At the ordinary meeting of the Institution of Civil Engineers, held on the 24th of April, a paper on the above subject was read by Mr. Edward Bayzand Ellington, M.Inst.C.E. The author observed that water power was no new force, but that, as formerly understood, it was limited in its application to systems of mechanism suitable for the low pressures found in nature. The effects obtained by the use of high pressure were so different in degree from all previous experience, that a new name was needed, and had been found in the term "hydraulic power." Bramah's genius produced the hydraulic press, and he clearly foresaw the future development and great capabilities of his system; but it was reserved for Lord Armstrong to work out and superintend the intricate details that had to be developed, before the system could be made fully serviceable. The public supply of hydraulic power in London constituted the latest development of this system. The hydraulic power was supplied through mains charged by pumping at a pressure of 700lb. per square inch. The first and largest pumping station had been erected on a site known as Falcon Wharf, about 200 yards east of Blackfriars Bridge. The engine house at present contained four sets of pumping engines, each set being capable of exerting 200 i.h.p. The engines were vertical compound, of a type comprising the advantages of a three-throw pump with direct connection between the pump plungers and the steam pistons. Each set of engines would deliver 240 gallons of water per minute into the accumulators, at 750lb. pressure per square inch, at a piston speed of 200ft. per minute. This was the normal speed of working; but, when required, they could be worked at 250ft. per minute, the maximum delivery being 300 gallons per minute. The condensing water was obtained from storage tanks over the engine house, and was returned by circulating pumps to one or other of those tanks. The water delivered into the mains was maintained all the year round at temperatures of between 60° and 85°. The boilers were of the double flued Lancashire type, and were made of steel. All were fitted with Vicars' mechanical stokers. At the back of the boilers was a Green's economiser, consisting of ninety-six tubes. The economiser and the stoker gear and worm were driven by a Brotherhood three cylinder hydraulic engine. The reservoir of power consisted of accumulators. The accumulators at the pumping station were two in number, each having a ram 20in. in diameter and 23ft. stroke. The weight cases were of wrought iron, and were filled with iron slag. The total weight of the case and load on each ram was approximately 106 tons, corresponding to a pressure of 750lb. per square inch. The storage tanks formed the roofs for the engine and boiler houses. The water for the power supply was obtained from the river Thames, and was pumped into the tank over the engines. The water passed through the filtering apparatus by gravity into the filtered water tank over the boiler house, which was 7ft. below the level of the unfiltered water tank. The filters consisted of cast iron cylinders, and each contained a movable perforated piston and a perforated diaphragm, between which was introduced a quantity of broken sponge; the sponge was compressed by means of hydraulic pressure from the mains. The delivery of power water from the Falcon Wharf pumping station was through four 6in. mains. The most distant point of the mains from the accumulators was at the west end of Victoria-street, and was 5320 yards, or just over three miles. To provide for all frictional loss in the pipes and valves, the accumulators had been loaded to 750lb., the stated pressure supplied being 700lb. per square inch. The total length of the mains at present laid was nearly twenty-seven miles. The mains were laid in circuit, and there were stop valves at about every 400 yards, so that any such section of main could be isolated. The method employed for detecting leakage was based upon an automatic record of the number of gallons delivered into the mains, and in cases of abnormal increase during the night, if found to arise during the early hours of the morning, the mains were tested. The power water used was invariably registered through meters on the exhaust pipes from the machines, and from the meters passed to the drains. There was a sliding scale of charges from 8s. to 2s. per 1000 gallons at 700lb. pressure per square inch, designed to meet, as nearly as possible, the variable conditions and requirements of consumers. The more continuous the use the lower the charges. The scale was intended chiefly for intermittently acting machinery, and experience had fully proved that these rates were sufficiently low to effect a large saving to the consumer in almost all cases, whether for a large or a small plant. The author believed any idea of supplying power from a central source at rates much below these to be chimerical. The practical efficiency of the hydraulic system might be fixed at from 50 to 60 per cent. of the power developed at the central station. No other method of transmission would, he thought, show a better result; and the general convenience and

Digitized by Google

simplicity of the hydraulic system were such that its use would hardly be affected, even if there were no direct economy in the cost of working.

In addition to the general supply of hydraulic power, in the City and adjoining districts, to the six hundred and fifty machines at present worked, a new departure had been taken by the application of hydraulic power to an estate at Kensington Court, the name given to an area of about seven acres opposite Kensington Gardens. Seventy houses and dwellings were to be built on this estate, of which thirty had been already erected. Each house was fitted with a hydraulic lift, taking the place of a back staircase, and the power supply was provided on the estate expressly for working these lifts. The driven machinery was of as great importance to an economical and satisfactory result as the distributing plant, but this obvious fact was not always understood. General regulations had been prepared by the author, defining the conditions to be observed by manufacturers in fitting up machinery for connection to the power mains. They were intended to secure safety, and an efficient registration of the quantity of power used; but they left the question of the economy and of the efficiency of the machines to be settled between the consumers and the makers. In London more lifts were working from the mains, and more power was used by them than by any other description of machinery. The number of all classes at present at work was over four hundred. The principal types in use were fully described. In some cases there had been, by adopting the public supply, a saving in the cost of working of about 30 per cent., as compared with the steam pumping plant previously in use. Lifts were now becoming so general, and the number of persons who used them was so great, that the author considered it necessary to urge the importance of securing the greatest possible safety in their construction, by the general adoption of the simple ram. Suspended lifts depended on the sound condition of the ropes or chains from which the cages hung. As they became worn and unreliable after a short period, it was usual to add safety appliances to stop the fall of the cage in case of breakage of the suspending ropes; but they could not be expected to act under all circumstances. As an indication of the important part which lifts occupied in a modern hotel, it might be mentioned that at the Hôtel Métropole there were, including the two passenger lifts and that for the passengers' luggage, no less than seventeen hydraulic lifts in use day and night, while the work done represented about 2000 tons lifted 40ft. in this time. The next largest use of the power was for working hydraulic cranes and hoists of various kinds along the river side, and in the city warehouses. It often happened that the pressure in the power mains was not sufficient for pressing purposes. The apparatus known as an intensifier was then used, by which any pressure required could be obtained. Hydraulic power was also used at Westminster Chambers, and elsewhere, for the purpose of pumping water from the chalk for domestic use. The pump was set going in the evening, and continued working till the tanks were full, or until it was stopped in the morning. For work of this kind, done exclusively at night, a discount was allowed from the usual rates. Mr. Greathead's injector hydrant, made at the Elswick Works, had been in use to a limited extent in London in connection with the power mains. A small jet of high pressure water, injected into a larger jet from the water works mains, intensified the pressure of the latter in the delivery hose, and also increased the quantity. By this means a jet of great power could be obtained at the top of the highest building without the intervention of fire engines. This apparatus enabled the hydraulic power supply to act as a continuous fire engine wherever the mains were laid, and was capable of rendering the greatest assistance in the extinction of fire; but there was an apathy on the subject of its use difficult to understand. In Hull, the Corporation had put down a number of these hydrants in High-street, where the hydraulic power mains were laid, and they had been used with great success at a fire in that street. The number of machines under contract to be supplied with power was sufficient, with a suitable reserve, to absorb the full capacity of the station at Falcon Wharf, and another station of about equal capacity was now in course of erection at Millbank-street, Westminster. The works had been carried out jointly by the author and Mr. Corbet Woodall, M.Inst.C.E.; Mr. G. Cochrane had been resident engineer and superintendent. The pumping engines, accumulators, valves, &c., and a considerable portion of the consumers' machinery, had been constructed at the Hydraulic Engineering Works, Chester. Sir James Allport, Assoc.Inst.C.E., who was the first to adopt hydraulic power for railway work, had been associated with the enterprise from the commencement of its operations in 1882. His wide influence and extended experience had greatly assisted the commercial development of the undertaking.

THE "UNIVERSAL" SCALING HAMMER.

Incrustation in marine and land boilers, although not so common now as it used to be, owing to the greater care exercised in the tending of boilers and the purifying of the feed water, is still sufficiently extensive to necessitate the periodical scaling of boilers. This process is often difficult of accomplishment, and entails a large expenditure for labour, owing to the confined spaces in which the scalers have to work. Hitherto, there have been few attempts to introduce suitable labour saving tools for this purpose, the ordinary slice which is used in places inaccessible to chipping hammers being an inefficient tool. The adoption of high steam pressures and smaller boilers, however, has increased the demand for improved scaling contrivances. Our illustrations show a new device for chipping the scale from tube plates, the necks of tubes and stays, and any flat or circular part of the boilers, which has been introduced by Mr. W. Cooper, Newcastle-on-Tyne. Fig. 1 shows a "universal" scaling hammer in two positions. On the left hand side it is fixed for removing the incrustation on the back of the combustion chamber of a marine boiler, and on the right hand side it is shown in position for performing the same operation on the necks of the tubes and stays. Fig. 3 shows a plan of the "universal" scaling hammer as arranged in the position shown in Fig. 1. In Fig. 2 we give an enlarged view of the apparatus and its immediate appendages. The apparatus consists of a universal joint B fixed to the slotted bar C by means of the bolt A and a

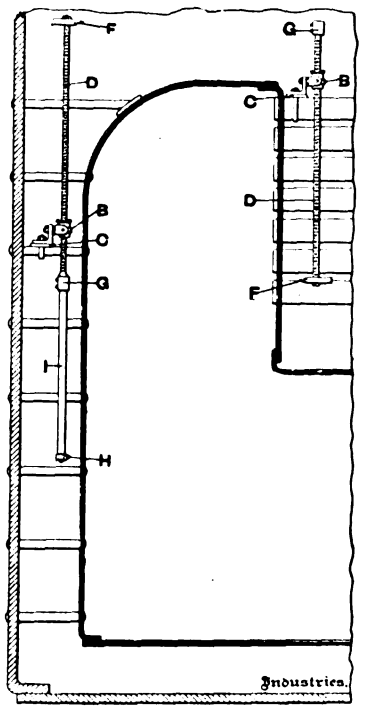

Fig. 1.

screwed bar D, which is provided with a hammer at one end and a socket at the other. When used in the combustion chamber, as shown in Fig. 3 and on the left hand side of Fig. 1, a lengthening bar with a hammer H is fitted in the socket G. The slotted bar is first fixed by two hooked bolts E to the stays (see Fig. 3). When the scaling hammer has been placed in

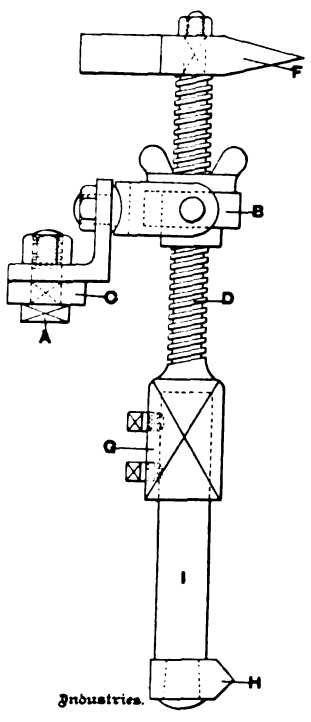

Fig. 2.

the desired position the T headed bolt A is passed through the slotted bar and fastened. The hammer H is actuated at the lower end of the bar D by moving the latter backwards and forwards at F, thereby striking the incrustation at right angles to the plate. As the work proceeds, the hammer is raised or lowered as required by means of the thumb screw shown on the universal joint B. In cleaning the tubes and tube plates of marine boilers the lengthening bar I is removed, and the screw bar fitted in a reverse position, as shown on the right hand side of Fig. 1. The slotted bar is fixed to the tubes by means of T bolts. By using the upper end of the screw G as a lever, the scaling may be accomplished both in the space between, and underneath and above the tubes, by means of the hammer F. In circular marine multitubular boilers of 6ft. 6in. diam., which have between the combustion chamber backs and

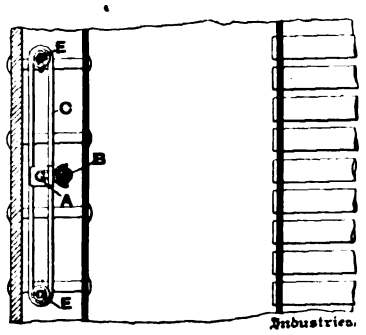

Fig. 3.

boiler shell a space of 3in. at the bottom and 4in. at the top, the plates were thoroughly cleansed of scale in a short time. It has also been successfully used in removing scale from the tube plates of the same class of boilers, and from the cross tubes of donkey boilers. It is claimed for this device that it may be efficiently used on any part of a boiler where scale is difficult to get at.

TASMANIAN RAILWAY CARRIAGES.

In a recent issue we published an article on the railways of Tasmania (see page 240), and we now supplement the information then given by an illustrated description of the passenger carriages in use on the Government lines in that colony.

Only two classes of carriages, viz., first and second, are employed; the first class are equal in comfort to those in use on English railways, whilst the Colonial second class are about on a par with the English third class. The fares charged are about 3d. per mile first class and 2d. per mile second class. In our illustrations, Figs. 1, 2, 6, and 7 represent a composite first and second class carriage. Fig. 1 is a half cross section of the first class and a half cross section of the second class portions, and Fig. 2 is an end elevation. This carriage consists of seven compartments, one second class at one end, with one first class smoking compartment adjoining, three first class compartments in the middle, and two second class compartments at the other end.

The carriage has an iron under frame carried on two four-wheeled bogies at 31ft. centres, the wheel base being flexible. There are fourteen india-rubber pads, 6in. by ¾in. by 1in. thick, fixed between the body and the iron under frames, to diminish shocks and vibration. The carriage is fitted with Clarke & Webb's continuous chain brake, the brake blocks being of cast iron and fitted to one side of each wheel. The bodies are 8ft. wide outside, and each first class compartment is 6ft. 6in. long between centres of partitions, each second class compartment being 5ft. 6in. long. The total length of the body of the carriage is 43ft. The height of body is 6ft. 3in. inside at the door, and a raised central roof is run from end to end, 4ft. wide outside, and 15in. high. The total height of the body from the floor to the top of the centre of the roof inside is 8ft. The compartments are all cross seated, with partitions from floor to roof. Each side of the first class compartment seats four persons, being divided by one arm and head rest in the middle of the seat.

All the frame work and panels which are visible are of Moulmein teak; the covered work is of Canadian oak, and the lining boards of St. Petersburg deals. The side lights, as well as the door lights, are arranged to slide up and down; they are supplied with louvre blinds, fitted with springs to hold them at any height. Each compartment is supplied with one roof lamp burning colza oil, with 1½in. wicks. The lamps were supplied by Messrs. Thomas Knight & Co., of Birmingham. The carriages have continuous footboards, as required by the Board of Trade. The wheels are 2ft. 7in. diam., 3ft. 6in. gauge, with Kirtley's spokes and Mansell rings; the axles are 4in diam. in centre, 4¾in. in the wheel seats, and the journals are 7in. long by 3½in. diam.

The under frames are made of channel and angle iron, connected by gusset plates and wrought iron knees riveted together at the joints.

Fig. 8 shows a longitudinal section, Fig. 3 a half section first class and half section second class, and Fig. 4 an end elevation of a special carriage used on the Parattah and Oatland Railway, a short line of light construction, the trains on which consist of a single engine and carriage. This carriage is of the American type, with a central passage 18in. wide, the doors being at each end, to which access is obtained by a flight of steps, so that passengers may enter and alight at any point. There are no regular

TASMANIAN RAILWAY CARRIAGES.

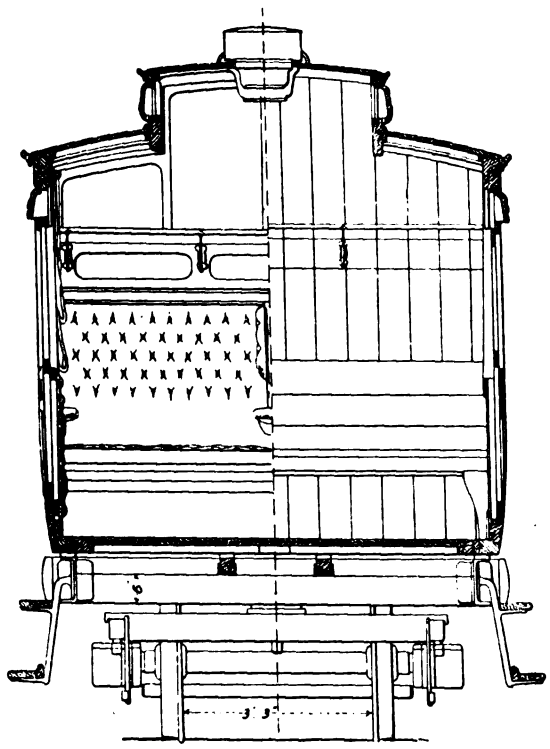

FIG. 1.

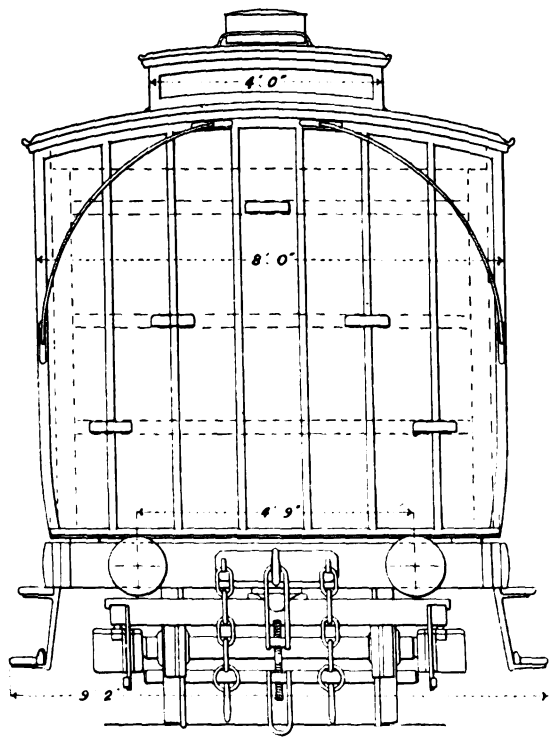

FIG. 2.

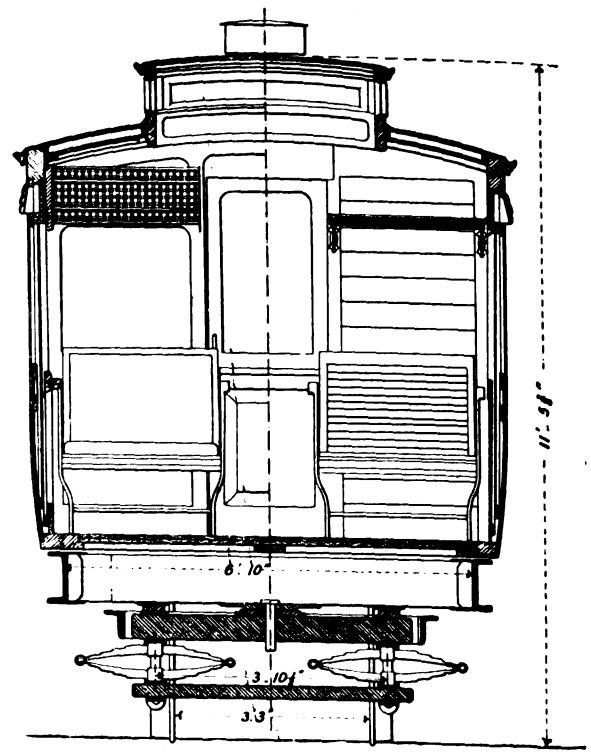

FIG. 3.

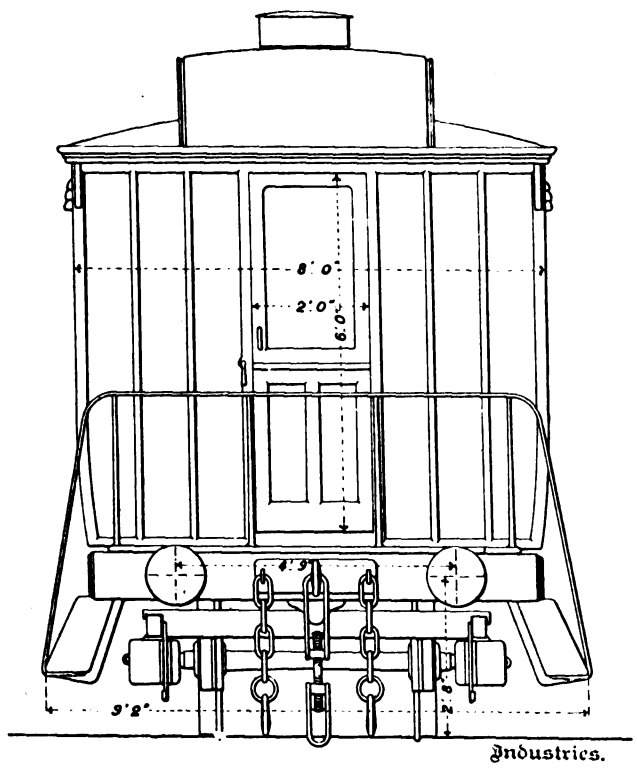

FIG. 4.

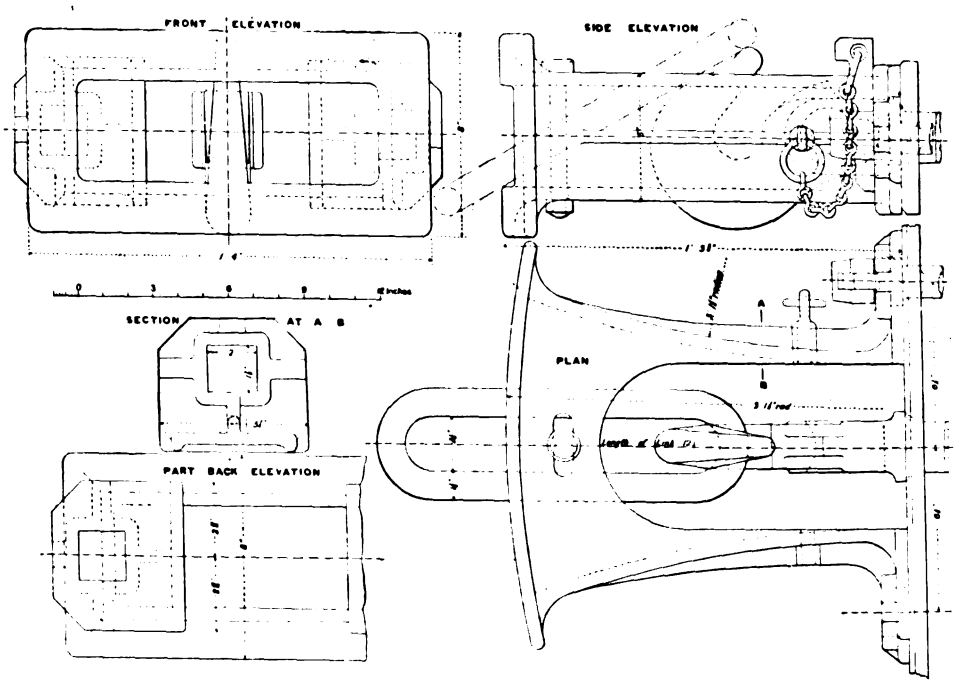

FIG. 5.

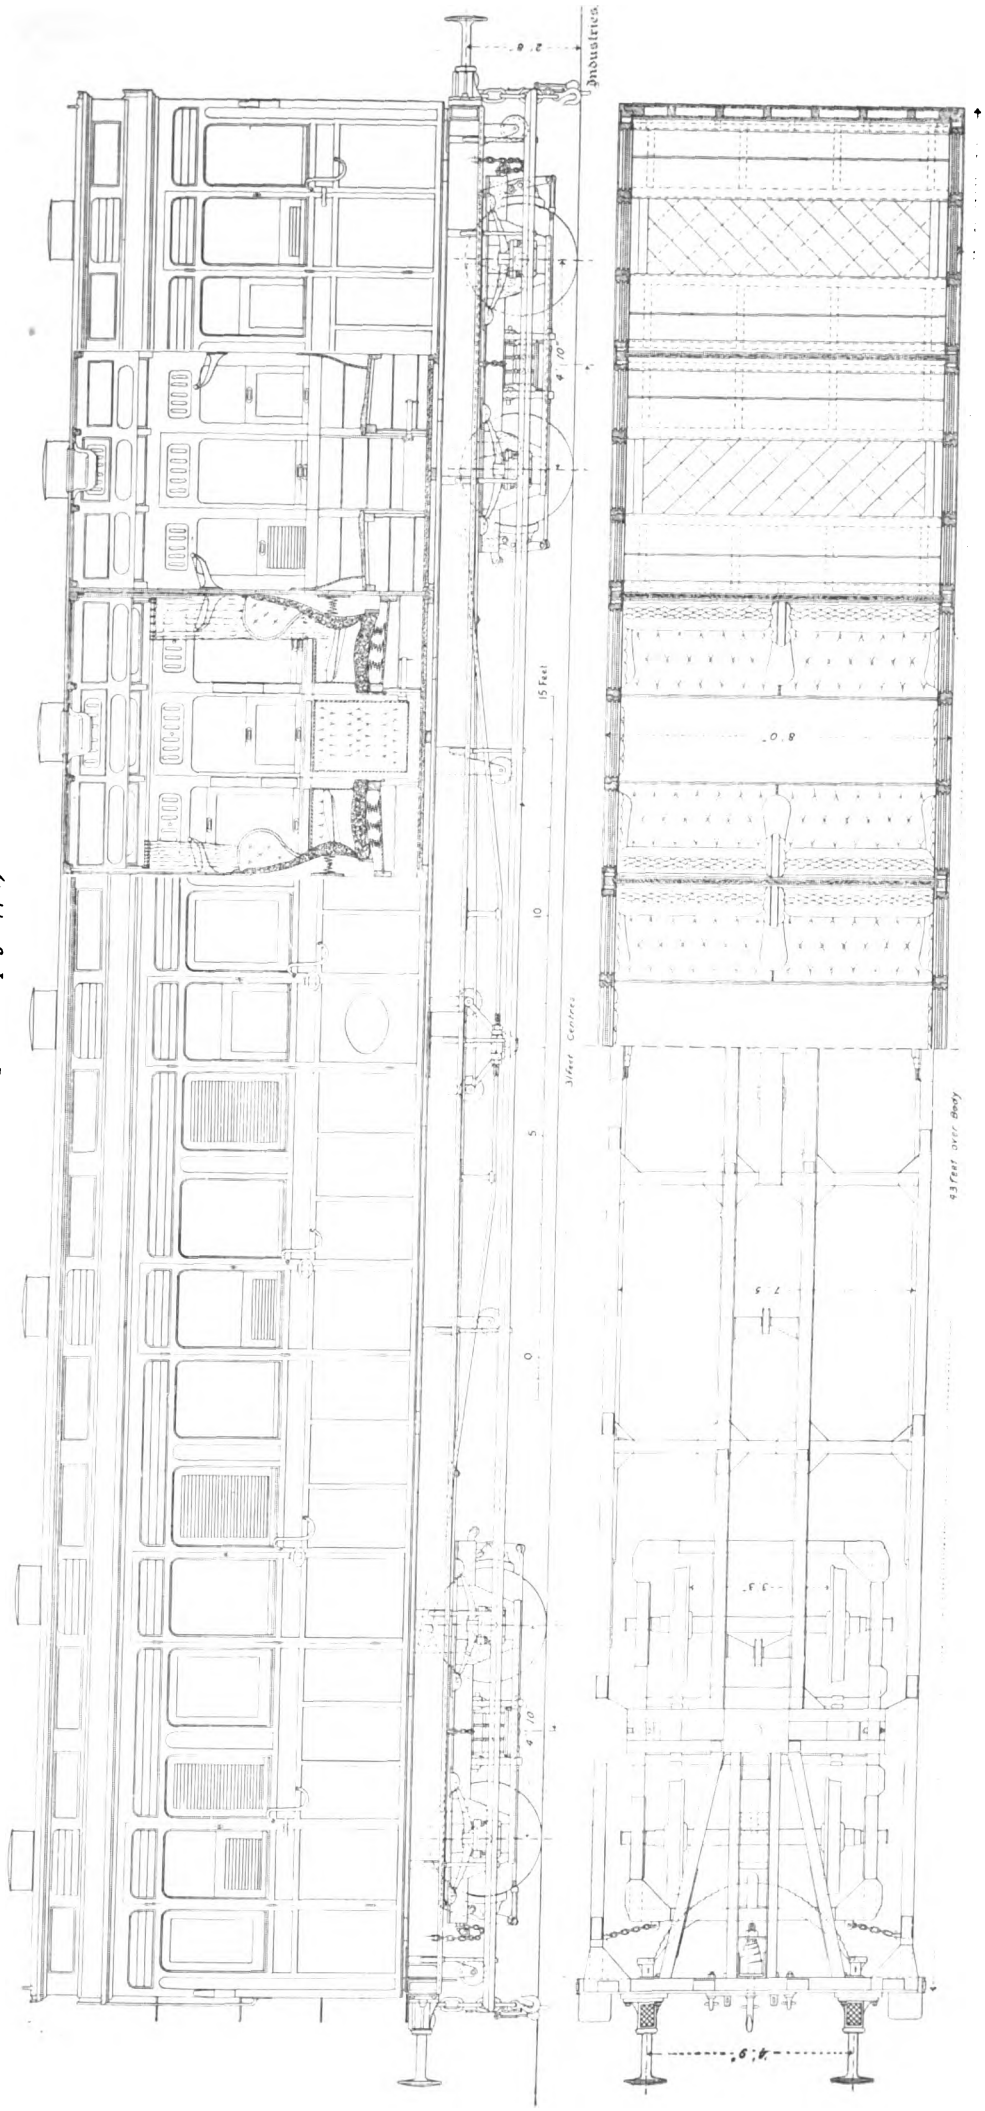
stations on this line, the train being stopped at the most convenient places to suit travellers. The general construction of the under frame is the same as for the composite carriage already described; the bogies are exactly alike, but in the present case are placed at 33ft. centres instead of 31ft. The carriage is 40ft. long over end pillars, with an additional length of 2ft. 9in. over each end platform. The seats are arranged crossways, with reversible backs, and the carriage is divided into two compartments by a partition in the centre, with a sliding door. The height and width are the same as in the ordinary carriages.



When the Government lines were made and the rolling stock ordered, a difference of opinion arose between the Government officials and the managers of the Tasmanian main line as to whether central buffers or side buffers should be used. The Government were in favour of side buffers; but the Tasmanian line strongly objected, as their stock was entirely fitted with central buffers. As there must be an interchange of rolling stock they contended that the new stock ought to be fitted with the same buffers, and that side buffers and central buffers could not work together in the same train. To overcome the difficulty Mr. Joseph Meilbek, Assoc.M.Inst.C.E., of 7, Westminster Chambers, Victoria-street, under whose supervision these carriages have been constructed, designed the neat form of removable central buffer shown in Fig. 5. At every station where there is a junction with the Tasmanian main line these special central buffers are kept in stock, and whenever any carriage passes from the Government lines on to the other line this buffer is slipped on to each end of the carriage, which is thus converted into a carriage on the central buffer system. This special buffer is complete in itself, and has two square holes through which buffer studs, fixed on the ends of every carriage, pass when the buffer is attached. These studs have cottar holes to fit a pair of cottars, which are chained to the buffer to prevent them being lost. The work of putting on or taking off the special buffer occupies no more time than the coupling of two carriages. All that has to be done is to pass the buffer over the studs, and drop in the two cottars. When a carriage comes off the Tasmanian Company's line, the action is reversed—the two cottars are withdrawn, and the buffer is free to be removed. The length of a side buffer is shorter than a pair of central buffers where they come together, so that there is plenty of clearance between the ends of a pair of side buffers and the end of a carriage without side buffers. The coupling arrangement with the special buffer is the same as with the ordinary central buffer.

The locomotives, carriages, and other rolling stock have been designed by Mr. W. E. Batchelor, the locomotive engineer. Messrs. Beyer & Peacock, of Manchester, are the locomotive builders; the Ashbury Carriage and Waggon Company, Manchester, the Bristol Waggon Works Company, the Birmingham Railway Carriage and Waggon Company, and Messrs. Brown-Marshall's, of Birmingham, are the makers of the carriages and waggons. The rails were manufactured by the Barrow Hematite Steel Company and the West Cumberland Iron Company.

FOREIGN INDUSTRIES.

(From our own Correspondents.)

PARIS, 1st May, 1888.

The Iron Market.—I am now in a position to give the particulars of the scheme which the manufacturers purpose to adopt to protect themselves against the merchants. It is proposed to establish a common agency at Paris under the control of one man, who will be accepted as the representative of all the manufacturers. It is argued that as one firm if existing alone could make its own prices, so when all are thus combined in one agency bound to act for the common good, the same result may be arrived at. The market is still somewhat weak here, and merchants continue to offer bars at £5. 12s. and joists at £5. 4s.; but elsewhere business is reviving. Orders come to hand pretty freely, and full prices are readily paid. The demand for wire and wire nails is very brisk, and is increasing. Galvanised wire is specially sought after. It now seems certain that, in the absence of political disturbances, trade will be fairly brisk throughout the early months of summer. The pig iron trade of the Meurthe-et-Moselle is in the best possible condition; the demand is steadily increasing, not only for France, but for Belgium, and prices move upward. The foreign trade in iron exhibits a tendency to shrink. In the first quarter of the year the imports of pig iron amounted to 31,169 (38,895) tons; those of finished iron to 5782 (8852) tons; and those of steel to 2428 (3848) tons, the quantities in brackets being those for the corresponding period of 1887. The exports of pig iron amounted to 8544 (10,358) tons; those of finished iron to 17,644 (17,418) tons; and those of steel to 5263 (13,188) tons. It is to be observed that the shrinkage in the exports is almost wholly in rails.

The Metal Market.—It is clear from the constant growth of the stocks in the hands of sellers that the consumption of copper is less than the production. Consumers, aware of this fact, defer the purchase of fresh material to the latest possible date, and then buy only for the wants of the moment. As a consequence the market is beginning to exhibit signs of weakness. Tin for prompt delivery has to be paid for at the prices which have been current for the last two weeks; but for future delivery large concessions may be obtained. Thus the tendency of the market is distinctly downward. Lead is active, and prices have further advanced 8s. a ton. Spelter is steadily declining.

Communication with the Continent.—The grounding of the "Invicta" on the Calais sands has directed public attention to the means of communication between London and the Continent, and particularly with Paris. It is interesting to trace, in connection with this subject, the progress of engineering science in the last fifty or sixty years. In 1828 the mail coach ran from London to Dover in 12 hours; 6 hours on an average were occupied in crossing the Channel to Calais by sailing boat; and the distance between Calais and Paris was covered by diligence in about 36 hours—a total of 54 hours from London to Paris. A few years later, a better built boat, the "Henry IV.," reduced the passage to 4 hours, and the diligence service was accelerated so as to save 6 hours on that portion of the journey. Twenty years later, in 1848, travelling on this route had been completely revolutionised. The time from London to Dover was by railway 3¼ hours, the steamboat "Courier" crossed the Channel in 2¾ hours, and the French railways conveyed the traveller from Calais to Paris by way of Lille in 8 hours, making a total of 14 hours for the whole journey. In 1868, the distance from London to Dover was traversed in 2½ hours; the "Samphire" did the passage in 1½ hours; and the journey from Calais to Paris was performed, *viâ* Boulogne, in 6½ hours—a total of 10½ hours. Another twenty years have brought further improvements. At the present time the London and Dover express is allowed only 1h. 45m.; boats like the "Victoria" and "Invicta" make the passage in very little over one hour; and the run from Calais to Paris, *viâ* Boulogne, occupies only 4h. 25m.; a total of 7h. 15m. actual travelling. A new steamer, the "Empress," is being built to make the passage in 50 minutes, and the Boulogne section of the line to Paris is being improved so as to reduce the time by 25 or 30 minutes. Thus visitors to the Great Exhibition will be able to perform the whole journey from London to Paris in about 6½ hours.

BERLIN, 30th April, 1888.

The Coal Market.—The condition of the coal market is only satisfactory as regards coking coal. Owing to the great demand for this variety the Königin Luise colliery has recently increased the price 3d. per ton, and this example has been followed by the colliery belonging to the Donnersmarckhütte; but for steam and household coal, colliery owners are obliged to make concessions, and a reduction in price of about 4d. per ton has taken place. The competition of collieries in Russian Poland is beginning to be more and more felt by Upper Silesian coal owners. The import of Polish coal is continually on the increase, and is partly due to the depreciation of Russian money, and partly to the reduction of freights on the Warsaw-Vienna Railway. Polish coal is from 1s. to 2s. a ton cheaper than Silesian coal, and consequently even those towns which are well situated for the Silesian trade, such as Posen and Gnesen, now import largely the cheaper coal. As there seems no prospect of Russian money rising in value, coal owners in Upper Silesia are agitating to induce the Prussian State Railway to make further concessions in their tariffs, so as to enable them to reach those towns at a cheaper rate.

The Iron Market.—During the past week a report has become current that the syndicate of rail makers has been dissolved, and this has caused a certain amount of uneasiness in the iron market. The firmness of the market depends to a great extent upon the existence of the various syndicates, and the dissolution of the rail makers' syndicate would endanger the condition of the others. Nothing definite is as yet known; but it is thought that the report has been circulated for stock jobbing purposes, since no confirmation of the fall of the syndicate has yet been received. Now that the inundations in Upper Silesia have ceased, business has resumed its normal aspect. The sales of crude iron have increased, and this branch has during the past week been more favourably situated. Common forge pig is still quoted at 50s., better qualities at 54s., and foundry pig at from 56s. to 60s. Engineering works continue well employed, and in some works more men have been engaged in consequence of the number of orders on hand. The output of the rolling mills is readily disposed of, this being especially the case with bars and girders, for which orders are numerous. Business in the crude iron trade of Upper Silesia continues satisfactory; but somewhat contradictory reports as regards future business are current. According to one of these reports the Donnersmarckhütte, anticipating some difficulty in disposing of about 6000 tons of forge pig, being part of their next year's probable output, has offered this quantity to the rolled iron syndicate at a reduction of 10s. per ton. On the other hand, the administrative council of the Tarnowitzer works have at their last meeting resolved not to make concessions in price for forward delivery, as they are confident that the demand will continue brisk, and prices remain firm. The Palatinate railway administration recently asked for tenders for the supply of various railway material. Messrs. de Wendel & Co., of Hagingen, obtained contracts for the supply of 7500 tons of ingot steel rails at 115s. 6d. per ton, and for 20,000 ingot steel fish plates at 113s. free at Ingbert. The Dortmund Union have obtained a contract for the supply of 7500 tons of steel rails, and 5600 tons of steel sleepers, at 110s.

Central Station Lighting.—In the electric light station at Lübeck, which is designed for 2000 lamps, but which will eventually be increased, a novel system of laying underground cables has been adopted. The method hitherto followed in Berlin and other towns consisted in the employment of either Edison tubes or Siemens lead covered cables, with an armature outside formed of spirally wound iron tape. To reduce the cost of the cables the iron armature has been omitted in the Lübeck cables, and the lead envelope is protected by a serving of jute heavily tarred. Since these cables are mechanically not so strong as those with an iron armature, they have been laid in flat channels of rolled iron with an iron lid. These channels are perforated at the bottom, so as to allow water which may find its way into them to pass out into the ground. Owing to the protection afforded by the iron channels, it has been found possible to lay the cables close under the paving stones. The junction, feeding, and distributing boxes are also smaller and less expensive than those used in Berlin. They are provided with short sockets, into which the iron channels fit. At the bottom of the boxes a plate of ebonite is fixed, to which are secured the various terminals and connections for the fusible plugs. Another departure has been made in the testing wires. These do not form part of the main cable as in Berlin, but are separate light cables brought back from the feeding centres to the station.

VIENNA, 30th April, 1888.

The Iron Market.—During the past week the iron market throughout Austria has continued firm, and business is very active. There is a good demand for agricultural machinery and implements, and this is bringing about an increase in the price of merchant iron. Considerable transactions are taking place in crude iron, and prices are as firm as in the winter months. Bar iron and black and tinned sheets are still in good request. Although the building trades are brisk the amount of business in building iron is not so great as was anticipated a few weeks ago. In Bohemia the condition of the iron trade has considerably improved, and the demand for girders and locksmiths' goods has especially increased. Large quantities of iron are being sold for agricultural and railway purposes, but bar iron and castings are neglected. Prices are generally well maintained, and a reduction has only taken place in galvanised sheets. In Hungary business is almost more favourable than in the western portion of the Empire.

Locomotives.—The Minister of Commerce has issued statistics showing the position of the locomotive trade in Austria, exclusive of Hungary. It appears that during the last year ninety-one new locomotives have come into service, of which number eighty-two were built by Austrian firms, while only nine were obtained from abroad, where three firms shared the orders. Locomotives before being allowed to be put in use must, according to a stringent police regulation, be submitted to an official test, and thus the tests are a reliable guide as to the number of new engines put on the road. The largest manufacturer of locomotives is the Austrian State Railway, which made last year twenty-four engines; a private company in Vienna made fourteen, and other railway works and private companies made smaller numbers.

Electric Lighting.—Considerable progress is being made in various Austrian towns with electric lighting. The total number of glow lamps now installed in Vienna may be estimated at eighteen thousand, and in addition there are about one thousand arc lamps in use. A small central station is projected for Neuhaus, in the south of Bohemia, where there will be a total of six hundred glow lamps installed, the motive power being supplied by turbines. Consumers will have to buy their own lamps, and pay for the current—not by meter, but at a fixed sum of 15 florins (about 24s.) per annum—for every 16 c.p. glow lamp fixed. In Pisek, also a town in Bohemia, a central station is in course of erection for twenty-two arc and one hundred glow lamps for street lighting; power will be supplied by a 45 h.p. water wheel. The station at Karolinenthal, near Prague, which I described some months ago, is in successful operation. There are now three hundred glow lamps in use, and the current is partly supplied direct from the dynamos and partly from Khotinski accumulators. One of the most complete installations in Bohemia is that on the Sophieninsel, in Prague, an island on which is a casino used for public entertainments. This installation has been erected by Herr Krizik, and consists of three Otto gas engines, each of 50 h.p., and a small gas engine for starting the big engines. There are four disc dynamos, each capable of supplying four hundred lamps. In the assembly rooms of the casino there are fixed five arc lamps, and nine hundred glow lamps; but as there is current to spare, some street lighting by arc lamps will be done from these dynamos. The whole of the plant for this installation, including the handsome electroliers, has been manufactured and supplied by Herr Krizik, who is also the contractor for the lighting. The light is paid for, not by the amount of current consumed, but by the amount of gas used in the engines, the charge varying from 20 kreuzer to 32 kreuzer per cubic metre, according to the number of lamps in use at a time. The gas for the engines costs 9½ kreuzer per cubic metre, or about 4s. 9d. per 1000 cub. ft., so that the contractor for the electric light receives a surplus of about 7s. on every 1000ft. of gas required, and this covers his profit, the payment of wages, lamp renewals, carbons, and other charges standing against the installation.

BRUSSELS, 1st May, 1888.

The Coal Market.—The situation continues favourable, and prices are very firm in all the districts. There is great activity on the State railways, 20,926 waggons of coal having been dispatched last week; and navigation on the Meuse to France having been resumed, numbers of boats are loading for the Ardennes district. The agitation still continues for lower railway rates, to enable our collieries to meet the German competition at home, which has been caused by the reduced tariff of the Grand Central. Owing to the brick making industry having been busy this year, there has been a good demand for inferior qualities of coal, which now show a tendency to rise. Stocks are very low in the Mons district, and coke is rising again. In the Liège district, steam coal and coal for metallurgical purposes are very firm; there is a slight falling off in the demand for household coal. During the first two months of the year the imports of coal and coke were as follow:—

From	Coal. Tons.	Coke. Tons.
Germany	59,975	2110
England	39,765	48
France	25,882	392
Holland	21,318	1270

Most of the imports entered as from Holland really come from Germany, which country shows a large increase at the expense of the other countries. During the same period our exports were:—

To	Coal. Tons.	Coke. Tons.
Germany	—	—
France	584,668	129,486
Luxemburg	15,823	30,316
Holland	21,730	—
Other countries	21,690	4,813

In addition to the above, we exported 45,954 tons of briquettes.

The Metal Market.—There is a falling off in the number of orders received, and in the export trade German and English competition is making itself severely felt. Steel is coming more and more into use for general purposes. Even in the construction of rolling mills it has nearly superseded every other variety of material. The Cockerill Company has obtained an order for 13,600 tons of steel rails for delivery at Venice, Ancona, and Brindisi, the prices quoted being respectively 111·75fr., 113·75fr., and 115fr. Delivery is to be made in June, July, and August. Tenders were also made for this contract by Bolckow-Vaughan, Ruhrort, and Terni. The Cockerill Company has also secured the supply of 2000 tons of steel rails to be delivered at Hamburg. The Société Franco-Belge furnishes two hundred waggons for the Roumanian railways. At the Belgian State railway contracts of last Tuesday Verhaegen obtained three mail vans at £304, Halot Frères forty-six waggon bodies at £64; Seneffe, thirteen at £50, and eight at £49; and Germain, forty-seven at £68. Trials of the Navez ores, made by several of our large establishments, have given excellent results. No buyer has yet been found for the blast furnaces of the old established firm of Dupret. There is some talk of a company being formed by English capitalists to purchase

Digitized by Google

the rolling mill of the Société de Châtelet-Marchienne, the Lion Belge rolling mill, the Châtelet blast furnaces, and other establishments in the same district.

Our Foreign Iron Trade.—The following are the figures of our foreign iron trade during the first two months of the year, in tons:—

	Imports.	Exports.
Steel ingots	10	211
Rails	60	701
Rolled steel	386	772
Pig iron	11,954	1,944
Old iron	1,998	107
Iron wire	567	556
Iron rails	65	2,531
Sheets	135	6,573
Rolled iron (various)	1,000	32,575

The imports show a marked increase as regards pig iron, which has been contributed solely by England and France. The total exports show an increase of 2000 tons, compared with the same period of 1887.

The Exhibition.—It is doubtful when the Exhibition will be opened; the 19th of May is now spoken of, but the Exhibition will not be complete till June. The English section, however, is almost finished; it is of an elegant design, and the way in which it has been erected by the English workmen has called forth favourable criticism. Nothing more is heard of the competitions which were the original object of the enterprise. The magnificent programme for lighting, of which so much was heard at first, has given place to a far more modest scheme. The illumination of the grounds will, however, be on a fairly large scale. The electric railway has been abandoned; but a small electric train, on the overhead conductor system, will be installed, the plant being brought from England. A Lartigue railway, as illustrated in *Industries*, Vol. I., page 317, will also be laid down. There will be a captive balloon, constructed by Thoulet & Cie. The tobogganing slide and switchback railway, and other attractions for the general crowd, are more likely to be successful than the scientific and industrial exhibits. The management of the Exhibition is trying to obtain an additional subsidy from the Government.

DÜSSELDORF, 30th April, 1888.

The Iron Market.—A little more life has shown itself this week in the iron market, both in the business in crude and in finished materials. This change for the better has given rise to a feeling of greater confidence, resulting in a more buoyant tone. A better demand has sprung up for spiegel pig for the United States, and forge pig for home consumption is again being actively dealt in. The renewed animation of the market for forge is a consequence of a reviving demand for bars, and an upward movement in the prices of coke. There is a steady current of business in basic pig, tending to increase, and foundry pig is being more largely bought. The total production of pig iron in Germany, including Luxemburg, in the month of March, amounted to 359,772 tons, against 315,713 tons in the same month of last year. This total was made up of 176,618 tons of forge and spiegel, 104,592 tons of basic, 34,781 tons of Bessemer, and 43,781 tons of foundry pig. The total production for the first quarter of the year amounts to 1,045,575 tons, against 885,818 tons in the corresponding period of 1887, a difference of 159,757 tons, or 18 per cent. The trade in finished iron and steel is a little more brisk in some of its branches. Bars are in better demand for home consumption. Manufacturers complain of prices being unremunerative. What justification there is for this dissatisfaction with the existing rates may be learned from a comparison of the current rates with those which prevailed a year ago. At the end of the first quarter of 1887 Rhenish-Westphalian forge pig was quoted 48s., and basic steel pig 43s.; while bars were being sold for £5. 10s. and common plates for £6. 13s. a ton. Now forge pig sells at 52s. and basic steel pig at 45s., while bars are quoted £6. 5s. to £6. 7s. 6d. and common plates £7. 5s. The market is slightly flat for joists this week; plates are in stronger demand, except in the Siegen district, where this branch of the trade is dull, and sheets are not much inquired after. Founders are generally very busy; but prices, especially for gas and water pipes, are low, being scarcely above the cost of production. The Rhenish Steel Works at Ruhrort tendered £5. 1s. 6d. per ton for 13,600 tons of steel rails for the Italian railways. This offer was underbidden by the Belgian Cockerill Company, who tendered £4. 12s.

Coal Tar Pitch from England.—English coal tar pitch is being largely imported into this district for briquette making. Two English vessels, the "Excelsior" and the "Eastern Belle," are now lying in Hochfeld Harbour, each laden with a cargo of about 140 tons of pitch from London. As return cargo, one will carry back to London empty bottles from Düsseldorf, the other mineral water from Remagen. Similar shipments each way will follow at short intervals.

LILLE, 1st May, 1888.

Textile Manufactures.—Business in textile goods has improved in some respects within the last few days. There is less distrust of the situation manifested, and the retail dealers seem disposed to buy more freely. In linen goods there is a steady current of business, but the weekly turnover is less than that of the corresponding season of last year. If this business follows its usual course, there will be greater activity after the middle of this month. In woollen goods there is a little more life, and manufacturers at Roubaix are beginning to regard the situation more hopefully; but there are no indications of anything like general activity. The demand has increased for fancy goods, striped fabrics being chiefly inquired after. Stock patterns of cloth are neglected. There is nothing new to report in the cotton goods trade, which remains dull, and there is no sign in the silk trade at Lyons. The Customs returns for the first quarter of the year show the foreign trade in textile goods relatively to the corresponding period of 1887. The declared values of the imports are: For linen goods, £56,080 (£54,080); for cotton goods, £480,000 (£639,280); for woollen goods, £576,360 (£578,040); for silk goods, £645,720 (£555,640). Of the exports the declared values are: For linen goods, £94,800 (£87,880); for cotton goods, £1,060,280 (£1,153,320); for woollen goods, £3,939,320 (£3,382,720); for silk goods, £2,396,920 (£2,454,040).

Flax and Yarn Markets.—The conditions of the flax markets have not changed since my last report. Business in home grown flax has been limited to a few unimportant transactions; but though the demand is light, offers are not pressed, and prices are maintained. There is scarcely more business doing in Russian produce, for which the quotations are the same as those of last week. The Ghent market is firmer, the demand being now fairly strong for home grown flax, and the quantity on offer small. Business in tows is dull. Yarns have been dealt in less briskly. The finer numbers are in good demand, at full prices; but the heavier sorts are somewhat flat, and concessions have to be made to buyers to induce them to deal in considerable quantities. Jute yarns are also quieter.

The Iron Market.—There is a steady and fairly abundant current of business in iron in this locality. Consumers, convinced now that lower prices are not to be expected, are giving out their orders more freely. Prices are very firm all round. Bars are quoted £5. 8s. to £5. 12s., and common plates £6. 12s. to £6. 16s. a ton. There is some talk of a further advance in these goods shortly; but it is not likely that manufacturers will push their advantage so rapidly, after the experience of the last few months. If the scheme for regulating the Paris market be carried into effect, a source of weakness will have been removed, and then higher prices may be expected.

The Export Butter Trade.—I directed attention some months ago to the efforts which were being made to extend the butter export trade of this district. Recent statistics show that considerable progress has been made, the trade with England having increased in a marked manner within the last three months. The total exports of fresh butter to England in 1887 amounted to 3,952,500lb., against 3,775,000lb. in the previous year. The quantity of salt butter sold to English consumers in the same time was 44,825,000lb., against 43,655lb. in 1886.

WINTERTHUR, 30th April, 1888.

Water Supply.—Herr Ritter, of Neuchâtel, has made a proposal to the municipality of Paris to supply that town with water from the Lake of Neuchâtel, the level of which is nearly 1000ft. above that of Paris. The distance is about three hundred miles. The quantity to be supplied is 20 tons per second, and the estimated pressure at Paris, after deducting loss by friction in the supply main, is 50lb. per square inch. The total energy therefore brought by water to the town of Paris would thus amount to over 8000 h.p. in falling water, or say 6000 actual h.p. obtainable from water engines.

Textiles.—According to figures which have been published by the union of Swiss silk spinners, there were last year in Switzerland 61 silk spinning mills, employing 5765 hands in the works, in addition to 2289 persons who were engaged in their own houses. The total wages paid during the year were rather less than was the case in 1885, although 300 more persons were engaged in the industry. The value of the exports from Switzerland in 1887 of cotton embroidered goods amounted in round figures to £3,600,000, whilst the exports of silk and linen embroidered goods in the same year were of the value of £400,000.

Extension of the St. Gothard Railway.—The second line of the St. Gothard railway has already been commenced, and active operations will shortly begin on the Faido-Rodi-Fiesso portion. This part of the line offers the greatest difficulties. It will involve the construction of two curved tunnels 15,000 metres long, and four straight tunnels of about 1000 metres, and two iron bridges of considerable span. The Faido-Airolo portion is to be completed by the year 1890; the Faido-Biaska portion by 1892; and the Erstfeld-Göschenen section by 1896. The total estimated cost is £650,000.

NEW YORK, 21st April, 1888.

The Coal Market.—In the anthracite coal trade it was hoped that the spring season would bring with it the usual activity; but this has not been the case. On the contrary, there is a disposition on the part of buyers to purchase only for immediate wants. Consumers are almost universally of opinion that lower prices will prevail. In the East, where navigation is just opening, there is a scarcity of coal; but the orders are only enough to supply present necessities, and this indicates the state of the trade everywhere. Production goes on at a great rate, and coal is being stored in large quantities. There has been no formal understanding about the output, but some steps in that direction are necessary, owing to the tendency of prices. The leading companies profess the most earnest desire to do all that is proper to maintain the trade on a profitable basis.

The Iron and Steel Markets.—The second quarter of the year has not opened very favourably for iron dealers. While there is probably a good amount of business in prospect, it will be at terms which cannot possibly leave much, if any, margin to manufacturers. Prices have been cut down far more rapidly than the cost of production has been reduced. There is a moderate degree of activity in pig iron. Standard brands, which are still scarce, are steady; but there is an increasing supply of "outside brands," the quality of which is generally uncertain. They are offered at lower figures than regular irons, but have not found much favour so far, and are not bought to any extent, except at extremely low prices, or in sample lots subject to approval. In this way options for thousands of tons have been bought; but whether they will result in actual sales remains to be seen, and will depend on how the iron turns out and how the market looks a little later on. It cannot be said that the position is any more settled than it has been for some time past, although the market is now so low that there can hardly be any further concessions; and when consumers realise this, purchases will be on a more liberal scale. The Thomas Iron Company have booked orders for over 30,000 tons since announcing the $20 rate for the year. Last year, after announcing their rate, the company had orders booked for 100,000 tons in less than a week. There has been a slight recovery from the rapid decline of blast furnace output which has been going on steadily since the beginning of the year; although there are fewer furnaces in blast now than there were a month ago, the output has increased, owing to some of the smaller furnaces blowing out and some of the larger ones starting again. On the 1st of April there were in blast 95 anthracite furnaces out of 198; 128 bituminous and coke furnaces out of 212, and 52 charcoal furnaces out of 175, having a total output of 110,769 tons. At present $20 to $21 per ton is the quotation for No. 1 foundry, and other grades in proportion. Southern and Western irons are more irregular, and are offered at from 50 cents to a dollar less than the quotations for local brands. There is a pretty fair demand for manufactured iron, and the business is improving slightly from week to week. Prices are somewhat irregular, and vary considerably with the size of the order. Plates have sold at 2 cents per lb., although in most cases 2·1 cents are asked; angles are quoted at 2·15 cents, and refined bars from 1·85 cents to 1·95 cents, but competition is very close. Business in steel rails is very quiet, and prices are steady at $31·50 per ton at mill as an inside price with large lots, and $32 for smaller orders.

The Metal Markets.—The copper market has been fairly active and steady during the past week. Most of the sales have been to consumers or for exportation, which partly accounts for the slight increase in price. There has been but little speculative buying, legitimate business alone being sufficient to strengthen the market. The stock in dealers' and consumers' hands is very small, so that the market is likely to remain firm for some time. Quotations are 16·85 cents to 16·95 cents per lb. for present delivery. Trading in tin has been very light, with declining prices. Prices for May delivery have fallen from 29·20 cents to 27·40 cents per lb. Plates are still dull, but prices remain unchanged. Stocks are small and very much broken, so that dealers have considerable trouble in filling large orders for one brand. Spelter is weak with a downward tendency, and little business doing.

PHILADELPHIA, 21st April, 1888.

Underground Cables.—The Town Council of this city have control of all electrical work, and some time ago they determined that all overhead wires should be undergrounded, which has been done. The engineer to the Council, Mr. D. R. Walker, has just sent in his annual report to the Mayor, describing the behaviour of these underground cables, which are used for telephonic, telegraphic, and electric light service. There are four companies in Philadelphia now using Waring underground cables, viz., the Brush Company, the Keystone Company, the United States Company, and the Underground Electric Light and Power Company. The Brush Company are using sixty arc lamps in one of their circuits, which is five miles long, and is worked at a pressure of 2800 volts, or about 45 volts per lamp. The lamps are generally placed at intersections of streets, and at a distance of about 500ft. apart. The cable for the Brush lamps consists of a seven strand 14 B.W.G., with insulation of from $\frac{1}{16}$in. to $\frac{4}{32}$in., and protected with a lead covering $\frac{1}{8}$in. thick. The same cable is used by the Keystone Company in a fifteen mile circuit at 2000 volts, and no difficulty has been found in working it. Along Chestnut-street the electric light cables are laid side by side with telephone and telegraph cables in a cast iron duct 20in. by 30in. In Broad-street the cables are laid in a wooden trough, covered with a plank and close under the pavement. According to the report, nine-tenths of the difficulties experienced with underground work were not in the cables themselves, but in the connections with the overhead portions. Mr. Walker also mentions an interesting case where lightning struck an overhead connection on an underground circuit, ran through three miles of cable, and burned the dynamo; the cable itself, however, was not injured.

FORMAL INVESTIGATION UNDER THE BOILER EXPLOSIONS ACT, 1882.

The report of the first formal investigation held under the Boiler Explosions Act, 1882, on the 11th, 12th, and 13th January, 1888, has just been issued, Messrs. H. R. Mansel-Jones and Druitt Halpin being the commissioners. The boiler explosion investigated occurred on the evening of the 11th October, 1887, at Leys Iron Works, Brockmoor, Staffordshire, belonging to Messrs. Brown & Freer. It was of the Rastrick type, heated by the waste gases from two puddling furnaces, seated and flued as shown by the accompanying illustration, in which Fig. 1 is a sectional elevation and Fig. 2 a plan. The boiler was 9ft. 3in. diam. and 17ft. 6in. high. The cylindrical part was made in two rings, each formed of nine plates. The top and bottom, which were hemispherical, were formed of sixteen and eighteen plates respectively. The vertical tube of the flue was 9ft. high, made originally in two rings of plating—the upper ring 3ft. 6in. diam. in four plates, the lower

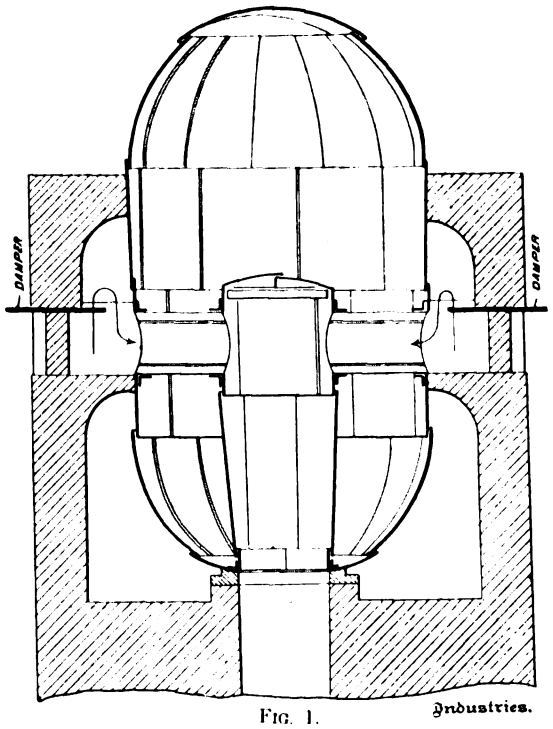

Fig. 1. Industries.

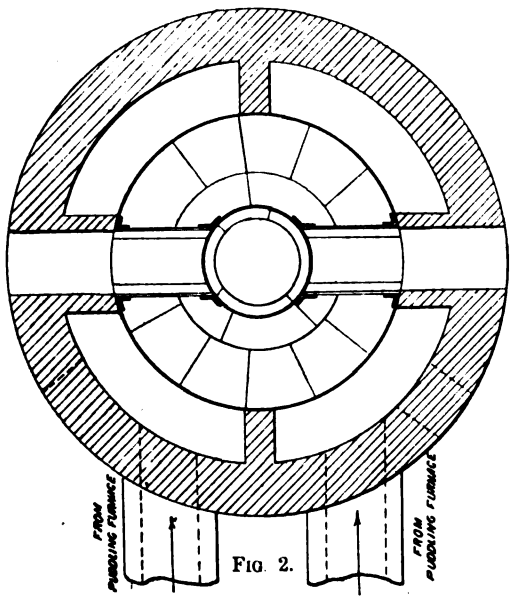

Fig. 2.

ring in six plates tapering to 2ft. 6in. diam. at the lower end; this ring had been cropped, and an additional ring 9in. broad fitted. The crown of the vertical tube was formed of two plates, and the cross tubes of four plates secured to the vertical tube, cross tubes, and shell by L rings 3in. by 3in. by ½in. All the plates appear to have been originally $\frac{7}{16}$in. thick, single riveted with lap joints, rivets $\frac{3}{4}$in. diam. and $1\frac{3}{16}$in. pitch. There was an internal manhole 15in. by 12in., with strengthening ring. The mountings consisted of one safety valve 5in. diam., with a counterbalanced lever with weights at each end loaded to about 30lb. per square inch; one stop valve; two floats with wheel standards to indicate the height of the water; one blow-off cock; one non-return feed valve, the feed valve and blow-off having only one pipe common to both, which is a most objectionable arrangement and liable to cause accident. There was no pressure gauge to the boiler which, from the evidence, appears to have been made by Messrs. Westwood & Wright, Brierley Hill, about 1853. The boiler was inspected about once a month by the engineer of the works, and, as might be expected from its age—thirty-seven years—had been extensively repaired from time to time; twice re-bottomed—once in 1863, and again in 1883. A report of these inspections had been kept by the engineer since 1870, of which the Commissioners somewhat suspiciously remark that "the entries are undoubtedly genuine, and made at the time they purport to have been made." The whole of these reports up to May, 1883, are appended to the report. Since 28th May, 1883, the engineer had inspected the boiler regularly, and with slight exceptions had reported it in good condition. In addition to this inspection, the boiler had been under the inspection of the Midland Steam Boiler Inspection and Assurance Company from the year 1863 to 1882, and from the latter date till the time of the explosion under its inspection and assurance for the sum of £500. A copy of the prospectus, names of directors, officials, rates of assurance, copy of proposal, copy of the policy and all its conditions, and also copy-reports of the insurance company upon the boiler are appended to the Commissioners' report, from which it may be inferred that this report is, at least, not wanting in the way of bulk.

Since the year 1863 the boiler appears to have been regularly inspected by the officers of the insurance company, and the reports clearly show that it had been in an exceedingly unsatisfactory condition for many years, as appear from the continuous leakage, caulking, chipping of seams, renewals of rivets, and patching alluded to therein. The last inspection was made by the senior inspector of the Midland Steam Boiler Inspection and Assurance Company, Mr. J. T. Short, the day before the explosion. The mill started about six p.m., and the boiler was worked as usual during the evening; three heats had been taken out of the furnaces, and the men were preparing for the fourth heat, when the boiler exploded, killing seven persons, and injuring nine others. The boiler gave way in the right flue, at one of the vertical seams of the lower belt of plating of the cylindrical part of the shell. The plates were blown violently outwards, the secondary rips following the line of rivet holes at the top, and the line of rivet holes of the curved end plates at the bottom, then vertically through the solid plates at each side within a few inches of the vertical seams of the next plate in the belt, and the plates were blown one to the right and the other to the left of the boiler site, scattering the surrounding brick work. The reactions of the outflowing steam and water through the opening thus made projected the boiler in the opposite direction, and it fell 34 yards from its original position, demolishing the shed in which the puddling furnaces stood. The plate that first gave way was cracked between the rivet holes of the joints. Most of the flaws have the appearance of having been of long standing, and were hidden by the inside overlap of the plates. The ring seam connecting the upper and lower belts of plates was also cracked for about 2ft. in length. The boiler does not appear to have been ever wholly stripped of brick work or subjected to a hydraulic test. The feed water by which the boiler was fed was taken from the hot wells of the condensing engines of the works, supplied from the adjoining canal, which is contaminated with sewage. From a report upon specimens of plates submitted to test by Professor W. C. Unwin, which is appended to the report along with his observations thereon, it appears that the mean breaking load of seven strips cut from the exploded boiler was 18·33 tons, with a minimum of 13·79 tons, the mean extension being 5·42 per cent., with a minimum of 1·5 per cent. Comparing these results with some tests of similar plates made by a Glasgow firm some years ago, which gave a breaking load of 22·42 tons, and a minimum of 20·20 tons, with a mean elongation of 8·72 per cent., and a minimum of 4 per cent., it would appear that the plates from the exploded boiler had only one half the combined resistance and ductility of similar plates from the same district. With regard to the cause of the explosion, the Commissioners say: "The remains of the boiler itself, together with the other evidence given before us, conclusively proves to our minds that the explosion was not due to over-pressure or shortness of water, but solely to the age of the major portion of it, an age which, having regard to the severe and alternating strains to which this class of boiler is subjected, must be considered very great. The plates and the rivet heads were very extensively reduced by wear from their original size, the seams had suffered severely from repeated chipping and heavy caulking, and the tests which we considered necessary to have carried out upon the original plates conclusively show that their quality had most seriously deteriorated, owing to their long exposure to intense and varying heat resulting in seam rips and edge cracks, which eventually caused the explosion, and it is impossible for us to explain how the inevitable calamity was so long deferred, particularly in view of the extensive seam rips existing in the boiler." . . . . . "No application was made as to costs." The last sentence is very disappointing, as it robs the whole report of the formal investigation of its distinctive value in a legal and moral sense, and reduces it to a mere report of preliminary inquiry. The report is, as we have stated, more diffuse and voluminous than usual, but that is of no real importance. This question of costs has apparently imparted a want of definiteness to the report, and prevented the Commissioners from plainly and clearly putting the blame, if any, where it is deserved, which is much to be regretted. Here is a boiler stated to be of a risky type, although it worked safely thirty-four years (from the evidence it would appear night and day), exploding in the usual course of work, apparently because it was thoroughly worn out, and no longer fit to withstand steam pressure. It does not appear that the actual remaining thickness of plate was ever ascertained, the boiler had not for the last twenty-four years at least been entirely stripped of brick work, nor even tested by hydraulic pressure. The insurance company do not appear to have recommended its replacement, nor does the possibility of a new boiler being required ever appear to have presented itself to the owners; and yet the Commissioners, deputed by the Board of Trade to make a formal investigation into the cause of its explosion, in framing an elaborate report of great length, formulate no conclusion as to where the responsibility should fall.

THE EFFECT OF OIL ON WAVES.

We have on several occasions mentioned the effect of oil on troubled waves, and stated a few of the experiments, both ancient and modern. The matter is now passing from the region of story to that of science, and is being discussed in papers and reports of Government departments and scientific societies, and a short time ago it was brought up in Parliament as deserving of attention. The Hydrographic Office of the United States has done the most effective service in bringing it into prominence and forcing it on the attention of the public. In 1886 the British Admiralty issued a memorandum on the subject, to which we directed attention at the time, and which was largely founded on the results published by the American Office. An interesting pamphlet has been published in Paris by Gauthier-Villars, the author being Vice-Admiral Cloné, and which contains a most admirable digest of the American results, supplemented by some striking examples which have occurred during the past year or two, and which further suggest some improvements in the methods of using oil for the purpose of stilling the waves.

The ordinary method of application is to hang canvas bags pierced with small holes, and containing a gallon or two of oil, over the side of the vessel. The oil slowly exudes through the holes, and spreads over the surface of the water with great rapidity and transforms a violent wave into a gentle swell, which lifts the ship without shock. Admiral Cloné has calculated that a film of oil, not thicker than one hundred-thousandth of a millimetre, is sufficient to produce this effect. In fact, it is shown that a small quantity of oil is more efficacious than a large quantity, as the thin film seems to spread more quickly, less than half a gallon per hour being sufficient to protect the largest ship. The oils most suitable for the purpose are those of the seal and the porpoise. Mineral oils have been used, although they are found to be too light, while the heavy vegetable oils congeal too quickly in cold seas.

Within the past few months various remarkable cases of the effect of oil on the waves have been published which are deserving of notice. Captain Kuhlmann, of the North German Lloyd steamer "Main," recently reported some experiments which he says were successful beyond conception. His words are as follow: "We were in 50°N. and 23°W., in stormy weather, with a high sea from the west. We steered west, and thus had the sea right in front of us, so that the vessel pitched and rolled badly, taking the heavy seas at the bows. The passengers could not remain on deck for the seas which rolled from the fore part and flooded the deck; and, moreover, the boats hanging in the davits threatened to be washed away in the shifting of the vessel. I resolved in this emergency to experiment with oil, and two pipes opening on the sides of the ship were stopped with tow and then filled with oil, which flowed slowly through the tow. I soon observed the effect, for from the foreshrouds to the stern no water came over. The sea had lost its power by reason of the oiling. We opened the doors and approaches, and the passengers could stay on deck at will. The oiling was continued seven hours, and the small quantity of 5lb. was used." A short time ago the steamer "Baumwall," of Hamburg (1050 tons), arrived at Leith with a cargo of wheat from Montreal. During the voyage heavy weather was experienced, and most of the deck fittings were washed away by heavy seas, which damaged the bridge. To prevent further damage being done, oil bags were hung over the side, and this had the effect of reducing the force of the waves. One of the most striking

Digitized by Google

cases is that of the "Stockholm City," which, on its passage from Boston to London, encountered a terrible gale, which raised waves to a very great height. The deck of the vessel was encumbered with two hundred head of horned cattle, which made the management of the ship all the more difficult. The captain caused bags of oil to be suspended from the stern, two amidship, and others at the bows. The effect was said to be instantaneous, and large breakers were converted into harmless swells, and not a sea was shipped during the remainder of the storm. These examples are sufficient to show that the subject deserves the attention of all who are interested in shipping, and to such we commend a careful perusal of Admiral Cloné's pamphlet, which we have mentioned.

THE "BAR-LOCK" TYPE WRITER.

A NEW type writer with this designation has just been introduced from America, and placed on the English market by Messrs. W. J. Richardson, of 12 and 14, Queen Victoria-street. The instrument may be described as a modified form of the well known Remington machine. The arrangement of the key board, and of the levers by which the type bars are actuated, is similar to that of the Remington; but, instead of placing a capital and small letter or two different signs on the same type bar, and effecting the change from one to the other by keeping a special key depressed while striking the printing key, and thus shifting the paper carriage, as in the Remington, each type bar carries only one type, so that seventy-two keys are used instead of thirty-six. This had already been done in the "calligraph," an earlier modification of the Remington; but in that machine the keys for capitals and figures were placed at each end of the key board, while in the present instrument the keys are arranged in six lines, sloping slightly upwards away from the operator. The small letters and stops are assigned to the three rows nearest the operator, and the capitals and figures to the other three rows, so that the change from a small letter to a capital is made by moving the finger three rows forwards. This appears a more convenient arrangement than that of the calligraph, but whether it is preferable to that of the Remington machine is a question which would probably be answered differently by different operators. The type bars strike downwards on the paper, instead of upwards, as in the Remington, and this allows the last line printed to be seen without lifting the carriage—a decided improvement. The depression of the keys is shorter and lighter than in the Remington, which is in favour of rapidity. Expert operators with the Remington can work the machine up to its extreme limit of about ninety to one hundred words a minute. Beyond this it is impossible to go, as the type bars then interlock. In the new machine, the distance through which the type bar has to rebound after printing a letter, in order to clear the next one struck, is considerably less than in the Remington, so that the mechanical limit to rapidity is higher. We do not, however, attach very great importance to this, as no operator could maintain a speed of much over ninety words for any length of time.

The bar-lock, from which the machine derives its name, appears to be an important improvement. A series of conical pegs are arranged in a small semicircle, having its centre at the printing point, and each type bar when printing a letter is locked between two of these pegs, which prevents the alignment becoming defective when the type bar sockets become loose through wear. The use of this device also enables the steel type bars to be made elastic instead of being rigid, as in the Remington machine, which obviates any possibility of injuring the type bars by striking two keys at once, or in too rapid succession. The pegs are made of phosphor bronze, to avoid wearing the type bars, and when they become worn they can be replaced at an insignificant cost. The paper carriage is lighter than in the Remington machine, and on completing a line the carriage is shifted, and the spacing for the next line simultaneously effected by a simpler movement of the hand, and with less exertion. As far as it is possible to judge from mere inspection, without the test of time, the machine appears to be well made, and to give every promise of durability.

GERMAN NICKEL WORKS.—A share company, with a working capital of £31,000, has been formed to establish works at Schwerte, on the Ruhr, for the production of nickel. The new company will be known as the Westphalian Nickel Rolling Works Company.

LIVERPOOL ENGINEERING SOCIETY.—The eighth meeting of the current session was held on the 25th ult. at the Royal Institution, Colquitt-street, Mr. Charles H. Darbishire, president, in the chair. The discussion of Mr. Webster's paper, entitled "Steam Boiler Explosions," was resumed and taken part in by members and visitors. After Mr. Webster had replied upon the discussion, Mr. C. F. Bamford read a paper entitled "Air Brakes." This paper was illustrated by numerous diagrams with the aid of an oxyhydrogen lamp, and dealt exhaustively with the question of continuous brakes for railway trains.

Notices of Meetings.

THIS WEEK.

GEOLOGISTS' ASSOCIATION.—Friday, 4th May, 8 p.m. Papers to be read on "Palæozoic Arcidæ," by Mr. J. Logan Lobley, F.G.S., and on "Pterodactyls," by Mr. E. T. Newton, F.G.S., F.Z.S., &c.

ROYAL UNITED SERVICE INSTITUTION.—Friday, 4th May, 3 p.m. Paper to be read on "Horse Artillery," by Captain M. Robertson, R.H.A.

NEXT WEEK.

SOCIETY OF ARTS.—Monday, 7th May, 8 p.m. Cantor lecture on "Decoration," by Mr. G. Aitchison, A.R.A.—Tuesday, 8th May, 8 p.m. Applied Art Section. Paper to be read on "The Decorative Use of Colour," by Mr. J. D. Crace.—Wednesday, 9th May, 8 p.m. Paper to be read on "Locks and Safes," by Mr. Samuel Chatwood.

ROYAL INSTITUTION OF GREAT BRITAIN.—Monday, 7th May, 5 p.m. General monthly meeting.—Tuesday, 8th May, 3 p.m. Lecture on "The Plant in the War of Nature."—Thursday, 10th May, 3 p.m. Lecture on "The Chemical Arts," by Professor Dewar.

ROYAL INSTITUTE OF BRITISH ARCHITECTS.—Monday, 7th May. Annual general meeting. Discussion of the annual report, election of officers, &c.

SOCIETY OF CHEMICAL INDUSTRY.—Monday, 7th May, 8 p.m. Paper to be read on "Standards of Light," by Mr. W. J. Dibdin.

INSTITUTION OF CIVIL ENGINEERS.—Tuesday, 8th May, 8 p.m. Ordinary meeting. Paper to be further discussed, "The Distribution of Hydraulic Power in London," by Mr. E. B. Ellington, M Inst.C.E. Papers to be read with a view to discussion, "The Tay Viaduct, Dundee," by Mr. Crawford Barlow, M.Inst.C.E., and "The Construction of the Tay Viaduct, Dundee," by Mr. W. Inglis, Assoc.M.Inst.C.E.

CIVIL AND MECHANICAL ENGINEERS' SOCIETY.—Wednesday, 9th May. General meeting for the presentation of report and election of Council, &c.

NORTH-EAST COAST INSTITUTION OF ENGINEERS AND SHIPBUILDERS.—Wednesday, 9th May. Closing meeting.

INSTITUTE OF PATENT AGENTS.—Wednesday, 9th May, 7 p.m. Ordinary meeting. Discussion of Mr. Hardingham's paper on "The Proposed Patent Law in Switzerland." Paper to be read on "Patent Claims," by Mr. J. Imray, Fel.Inst.P.A.

IRON AND STEEL INSTITUTE.—Wednesday, 9th, and Thursday, 10th May, 10-30 a.m., and on Friday, 11th May, if necessary. Papers to be read as far as time will permit. Adjourned papers (1) "On the Mutual Action of Sulphur and Silicon in Iron at High Temperatures," by Mr. T. Turner; (2) "On the Use of Water Gas for Metallurgical Purposes," by Mr. A. Wilson; (3) "On an Imperfection in Mild Steel Plates, considered Chemically," by Mr. H. Eccles; (4) "On the Mechanical Apparatus for Continuous Moulding at the Works of M. Godin, Guise," by Mr. Jas. Johnston; (5) "On the Effect of Arsenic on Mild Steel," by Messrs. F. W. Harbord and A. E. Tucker; (6) "On the Manufacture of Ordnance at Trubia," by Major Cubillo. New Papers: (7) "On the Melting of Wrought Iron or Steel Scrap mixed with Ferro-Silicon in Cupola Furnaces," by M. F. Gautier; (8) "On the Behaviour of Arsenic in Ores and Metals during Smelting and Purification Processes," by Messrs. John Pattinson and J. E. Stead; (9) "On a New Instrument for the Measurement of Colour, more especially as applied to the Estimation of Carbon in Steel," by Mr. H. Le Neve Foster.

SOCIETY OF TELEGRAPH ENGINEERS AND ELECTRICIANS.—Thursday, 10th May, 8 p.m. Paper to be read on "The Risk of Fire Incidental to Electric Lighting," by Mr. W. H. Preece, F.R.S.

PRICES CURRENT, 3RD MAY.

Quotations at per ton, unless otherwise specified.

Messrs. Carrick & Brockbank, Manchester, report as follows:—

COPPER has remained without much change since our last, to-day's price being £80 to £80. 10s. There are sellers for delivery in three months at about £5 per ton less, the rapid fall in tin having weakened the market for copper. It is reported that M. Secrétan has given it out that the copper syndicate, of which he is the head, are not affected by the collapse of tin.

TIN.—The great speculation by which this metal was forced up from £106 to £166, collapsed at the end of April. The price was kept up by steady buying, so as to exact the heavy differences upon sales made some time ago for April delivery, at low prices. The moment it became known that the syndicate had ceased buying, the price fell at a bound £60 per ton. It seems likely that prices will recede still further, as stocks are heavy and the production of tin has largely increased. To-day Straits tin, spot, is quoted £89 to £90; English, nominal.

LEAD.—Quiet and rather easier.

SPELTER improving. The fall in price has been considerable, and the present position of this metal is attracting attention. Warrants are quoted £17. 12s. 6d. to £17. 15s. per ton—a very low price.

CARRON PIG IRON—BRAND "CARRON."

Present prices of "Carron" pig iron are as follow:—

HOME INDUSTRIES.

MANCHESTER, 3rd May, 1888.

The Engineering Trades.—Engineers continue to be fully employed. There is still a brisk demand from India and the Continent, but very little new work is being received from home consumers. Mill gearing is in good request, and most millwrights are fully occupied, especially in the East and North-East Lancashire districts. The extension of weaving sheds still continues, and there is consequently a demand for shafting and gearing. As we have before noted, it is now becoming almost the universal practice to use steel instead of iron for this purpose, and fully 75 per cent. of all the work in hand is being carried out in that material. Boiler makers are well supplied with orders, and there appears to be no prospect of any diminution. Prices, however, are not so good as formerly, as the extensive use of special tools in this department tends to keep them low. Locomotive engineers are finding work a little easier to obtain. The condition of tool makers is also improving, but there is still plenty of room for improvement. Machinists have in many cases sufficient work to keep them employed for several months. Some good orders on Indian and Russian account have been recently placed, and Japan is also becoming a very good customer. The orders coming from India are mostly for ring spinning machinery, and it is also worthy of notice that weaving is being rapidly extended in that country. In miscellaneous engineering there is a quiet tone prevailing. Hydraulic engineers especially are doing badly, and copper smiths and brass founders are poorly employed. The phenomenal fall in tin from £166 to £103 per ton will enable makers to reduce the price of brass, and will permit of its use in larger quantities. Constructional iron work is not much sought after, and the prices which are being accepted are very low. Cast iron pipes for water and gas purposes have been taken at a rate of £3. 10s. per ton, a price which can leave very little if any margin of profit.

Technical Education.—A discussion on this subject was concluded at the last meeting of the Manchester Association of Engineers. There was a general agreement that some movement in this direction was necessary, but it was pointed out that there was a danger of exaggerating the importance of the subject. It was practically confessed that no system of technological instruction conducted in schools would be satisfactory as a sole means of education, and could only be recommended as an accessory to workshop practice. Eventually a committee was formed to draw up a syllabus of subjects which it was desirable should be studied by youths employed in the workshops. In this connection it may be mentioned that the designs for the new technical school at Blackburn have been considered, and those of Messrs. Smith, Woodhouse, and Willoughby, of Manchester, have been placed first in order of merit. The foundation stone is to be laid by the Prince of Wales on the 9th inst., and the estimated cost of the building is to be £25,000.

The Ribble Navigation Works.—The Bill empowering the Preston Corporation to spend more than £500,000 on the completion of this scheme has been before a House of Lords Committee for some days past, and has resulted in the limitation of the sum to be expended to £200,000. This, it is calculated, will allow for the completion of works at present undertaken, and for the payment of present liabilities.

A New Industrial Movement.—A movement is on foot in North-East Lancashire for the establishment of "self help weaving companies." Each weaver is expected to take at least one share of £5 value, which is to be paid up by instalments out of the wages earned, and the profits made after full allowance for depreciation, &c., are to be divided amongst the whole body of shareholders *pro rata*. This is a new development of the system of industrial partnerships, and it will be interesting to watch the working of the scheme.

LONDON, 3rd May, 1888.

The Money Market.—The general tone of the money market has become firmer, and rates will remain so to the end of the week in consequence of requirements for a couple of loans, one for India and the other for New South Wales. There have been considerable withdrawals of bullion, chiefly for the Cape and South America; and as further exports are anticipated, lenders have been keeping up the charges for loans for longer periods than a few days. Business on the Stock Exchange has been somewhat restricted this week owing to the May Day holiday. Prices have shown an inclination to rise all round. Foreign stock has advanced on account of the favourable reports of the Emperor Frederick's condition, and on account of the absence of disturbing news from Paris. Though some disquieting intelligence comes from South-Eastern Europe, Turkish stock has improved; Egyptian issues have resumed the upward tendency, which was checked by reports of the intended conversion of the preference loan. Home railway stocks are steady; the approach of summer weather is telling well upon the Southern lines, whose stocks should prove good purchases at present. The unfortunate Hull and Barnsley ordinary has now receded to the price which ruled before its revival, which was caused by the report of the negotiations with the Midland Railway. All hope of an arrangement of the kind is now abandoned. American railway stocks have begun to rise upon better traffic prospects, and in sympathy with the improved feeling in all the markets. The collapse in the tin market makes copper shares rather insecure, the same persons being interested in the "rig" in both metals. While so many new companies are being floated, the disappearance of one recently brought out may almost pass unnoticed; but as *Industries* was the first journal in the Kingdom to warn the public about the machine made bottle companies, we may note that the European and American company set on foot to exploit the much vaunted and hitherto unproved invention of Mr. Ashley has gone into voluntary liquidation. The directors have been generous enough to bear the whole of a very considerable loss.

Companies.—There is no falling off in the number of companies which are being promoted, as may be seen from the following long list of those which, among others, have been registered since our last report: Hadfield's Steel Foundry Company, Limited, with a capital of £110,000, to take over the business carried on at the Hecla Steel Foundry, Attercliffe, Sheffield; the Stanley Fire Proof Lathing Company, Limited, with a capital of £65,000; Anti-Friction Conveyor and Grinding Machinery Company, Limited, with a capital of £10,000, to carry on the business of general millwrights and mechanical engineers, and to acquire the business of Mr. Julius Schlesinger, 16, Mark Lane, E.C. (the Anti-Friction Conveyor was described and illustrated in *Industries*, Vol. II., page 212); Crypto Cycle Company, Limited, with a capital of £20,000; Electric Date and Time Stamp Company, Limited, with a capital of £100,000; Anglo-American Self Opening Square Paper Bag Machine and Manufacturing Company, Limited, with a capital of £100,000; Honduras Railway Company, Limited, with a capital of £8,000,000; Reynold, Limited, with a capital of £10,000, to manufacture earthenware goods, asbestos fuel, &c.; the Bostwick Gate and Shutter Company, Limited, with a capital of £25,000, to purchase the patent rights for inventions respecting folding steel gates and shutters, and to carry on business as engineers and ironmongers; South Down Metal, Chemical, and Brick Company, Limited, with a capital of £40,000; the Hele Cross Pottery and Terra Cotta Company, Limited, with a capital of £10,000, to purchase the pottery business now carried on by the Torquay Terra Cotta Company, Limited; Patent Lath, Splint, and Match Syndicate, Limited, with a capital of £10,000, to acquire inventions in machines for rending laths and cutting veneers; Guion Steamship Company, Limited, with a capital of £300,000; Thornebury Light Company, Limited, with a capital of £20,000, to carry on the business of light and lamp manufacturers; the Auxiliary Railways Company, Limited, with a capital of £1,000,000, to promote railways, tramways, and auxiliary railways in the United Kingdom, India, or foreign countries; the Colorado Gold and Silver Extraction Company, Limited, with a capital of £100,000; Normal Manure Company, Limited, with a capital of £10,000, to carry on the business of manufacturers of chemicals, artificial manures of all kinds, and guano from sewage; C. W. Boot & Co., Limited, with a capital of £10,000, to carry on the business of worsted spinners, &c., at Ponsanooth, Cornwall; Driffield Pure Linseed, Cotton, and "Union" Cake Company, Limited, with a capital of £54,000; Ashworth Brothers & Co., Limited, with a capital of £10,000, to carry on the business of an electric light company in Manchester and elsewhere in Lancashire; the Iron and Land Company of Minnesota, Limited, with a capital of £1,000,000; the Divisidero Gold and Silver Mining Company, Limited (Salvador), with a capital of £200,000; the New Drws-y-Coed Copper and Silver Lead Mines, Limited (Wales), with a capital of £50,000; Gwin and Singer United Tin Mines, Limited (Cornwall), with a capital of £45,000; the Bangor, Carnarvon, and Henddol United Slate Quarries, Limited, with a capital of £100,000; Mexican Coal and Iron Company, Limited, with a capital of £80,000; the Namaqua Copper Company, Limited, with a capital of £200,000; Jay Hawk Mining Company, Limited (Montana), with a capital of £175,000; Moodie's Golden Hill Gold Mining Company, Limited (Transvaal), with a capital of £33,000; the Dalmatia Mine, Limited (California), with a capital of £60,000; Havelock Gold Mining and Exploration Company, Limited (South Africa), with a capital of £120,000; London and Brazilian Exploration, Land, and Public Works Syndicate, Limited, with a capital of £20,000; Standard Mining Company, Limited, with a capital of £250,000, to acquire mines in Great Britain and Ireland; Cae Coch Pyrites Mine, Limited (Wales), with a capital of £20,000; and Silver King Mining Company, Limited (California), with a capital of £400,000.—Mr. W. H. Smith has stated in the House of Commons that the nominal capital of companies registered between the 1st of January and 17th of April of this year amounted to £100,206,857, as compared with £40,525,266 in the same period of last year.

Metals.—Messrs. Merton gave the stocks of copper in England and France on the 30th April at 57,449 tons, or with the quantities advised for Chili and Australia, 64,349 tons, as compared with 51,797 tons and 58,747 tons on 31st March of this year, and 48,722 tons and 56,172 tons on 30th April, 1887. In tin there has been a sudden collapse, the cash price of "Straits" having fallen £60 in two days.

Shipbuilding.—Returns have been compiled by Lloyd's Register of Shipping which show that on the 31st March there were 302 steamers and 78 sailing vessels building in the United Kingdom, against 247 and 80 respectively at the same date last year. The gross tonnages of the two classes of ship were 538,944 tons against 374,037 tons, and 55,482 tons against 66,542 tons respectively. Of the steamers all but about 20,000 tons were of steel, and of the sailing vessels nearly 34,000 tons were steel.

Railways.—The gross receipts of the twenty-three principal railways in the United Kingdom for the week ending 22nd April, amounted to £1,210,029 on 15,850½ miles, as compared with £1,175,077 in the corresponding period of 1887, when the mileage was 15,724 miles. An increase is thus shown in the mileage of 126½ miles or 0·8 per cent., and in the receipts of £34,952 or 2·9 per cent.

GLASGOW, 3rd May, 1888.

General Business.—The stock markets began the week with a tone of considerable liveliness, and a large amount of stock changed hands. In some securities, especially Americans, prices rose sharply from the closing figures of last week. In metals the attention of speculators has been turned to tin, which has dropped from some unexplained reason. It is not believed that there has been much buying in Glasgow for some time. Steel and iron manufacturers still continue to be fairly employed. It is rumoured that a very large contract has been placed with Messrs. Beardmore for steel boiler plates and crank shafts for two cruisers now being built at Barcelona for the Spanish navy. Local boiler makers are well employed, and there is a considerable amount of work of moderate dimensions on hand. Shipbuilding and marine engineering are both at the moment suffering from a lull, although the contracts booked at the close of the year are, of course, not yet out of hand. Mechanical engineering generally is moderately active, though there is very little prospect of any fresh work. Joiners, show case makers, and decorators have been very busy over the Exhibition, and over three thousand persons are being employed within the walls. It is understood that a large number of tradesmen have come to town from the country districts, and have during the past year found employment at the Exhibition buildings. Many of these are, it is said, intending to emigrate whenever they are paid off.

Trial of an Asphalt Boiler.—The Municipal Appliances Company, Liverpool, invited the Corporation of Glasgow to make an experimental trial of their new asphalt boiler on Monday last. The feature of the boiler is that the fumes are led from the smoking mixture into the flue, and melted bitumen and tar are drawn off by a tap, instead of being ladled out from an open boiler as is customary.

Mineral Shipments.—The coal shipments for the month of April show a serious falling off, when compared with the corresponding figures for April, 1887. Coal shipments in April, 1887, aggregated upwards of 82,000 tons; in April, 1888, they were only 43,000 tons. The decrease for the year, so far as it has gone, is 118,600 tons, a decrease of almost 50 per cent.

The Glasgow Subway Bill.—The Glasgow and Suburban Subways Bill is now before a Select Committee of the House of Lords. In order to secure the consent of the Corporation of Glasgow to the scheme, the company has offered to pay a sum of £65,000 to the Corporation as wayleave. A number of new features are embodied in the proposal. It is proposed that the tunnel should have an outer skin of iron, then a shell of concrete, then an inner skin of iron. At the point where the Kelvin bridge crosses the river, in immediate proximity to the proposed line of the subway, the promoters propose to co-operate with the authorities in building a new structure, which should comprise a subway and bridge combined. The trains will be drawn by ropes actuated at a central station. The speed of the rope will be eleven miles per hour. The evidence of the engineer, Mr. Alexander Simpson, was taken on Tuesday, and that of other parties to the Bill followed.

The Exhibition.—During the past week rapid progress has been made in placing the exhibits. The exigencies of the case have compelled the Executive to extend the time for receiving exhibits, and now to-morrow, Friday, is announced as positively the last day. The progress of every day makes it more possible to estimate the educational and industrial value of the Exhibition, and there is now no doubt that with due allowance for deficiency in certain departments, for example, in marine and locomotive engineering, the Exhibition is one of the most diversified and instructive of world shows. The improvement in the condition of the Emperor of Germany now removes almost all doubt as to the presence of the Prince of Wales. The Indian artisans who are to work at their respective handicrafts in a row of workshops in the Indian section, have arrived in Glasgow. A range of buildings has been erected in the Exhibition grounds for their accommodation. The trades represented by the Indian artisans are jewellery, pottery, wood carving, and confectionery.

(From our own Correspondents.)

LIVERPOOL, 2nd May, 1888.

Liverpool Overhead Railway.—The Mersey Docks and Harbour Board obtained Parliamentary powers in 1882 for the construction of an overhead railway along the line of docks; they took no further action in the matter until last year, when they applied to Parliament and obtained an extension of time and powers to make certain deviations at the Stanley Dock, the George's Dock, and the Queen's Dock, and also to lease the undertaking to a private company. The Board were of opinion that as a public trust they ought not to burden themselves with

Digitized by Google

the administration and management of such a railway; at the same time they felt that they ought to be the legal owners of the line, that those who worked it should be under their control, and that the Dock Board should have it in their power to settle what the lessees might and might not do. Application has been made to the present Parliament for power to promote a company on the above conditions. The only opposition to the Bill was from the Bootle Corporation. The Bill, after consideration by a Select Committee of the House of Lords, was passed on Monday last with certain amendments, by which the Bootle Corporation will have reasonable access to the quays and to the proposed ferry. The principal promoters are Sir William B. Forwood, Mr. Robert Alexander, and Mr. Arthur Earle, and the proposed capital is £450,000 in shares and £150,000 in borrowing powers.

SHEFFIELD, 2ND MAY, 1888.

THE HEAVY TRADES.—There is not much change in the price of iron, though quotations for some sorts are slightly easier. Angles are quoted at from £5 to £5. 10s., and up to £6. 10s. for best kinds. Rods can be obtained in quantities at £5. 5s., though the superior makes are fetching £6. 10s. and £7. Hoops and plates are in better request, and the tendency is perhaps a little firmer. The demand for Bessemer steel continues to be extensive, and the crucible houses are very busy. But everywhere there are complaints of the increasing keenness of competition; a great bulk of billets has been sent out during the past month at exceedingly narrow profits. The struggle for orders for steel rails on foreign account becomes more accentuated year by year, and the tendency of the buyer is more and more to look at the lower quotations rather than to consider the wearing power of the rails. In order to quote with any chance of success in large contracts, English makers are doing much to reduce the cost of production; but they are still under-quoted by Belgian and other foreign houses. There is a steady inquiry for shipbuilding material, such as plates, engines, propellers, and one or two Sheffield concerns are very busy in these departments. Hadfield's Steel Foundry Company is doing a large trade not only in heavy machinery and steel castings, but in steel shells. The latter branch of manufacture is one which the company has recently taken up with much success, their projectiles having stood very severe tests. There has been a keen competition for shares in this concern. At the armour plate works there is a little more being done; and Messrs. T. Firth & Sons are well engaged on war material. Messrs Davy Brothers have recently received additional orders for heavy machinery, and other engineering firms in the town are tolerably well employed.

LEEDS, 2ND MAY, 1888.

IRON AND STEEL.—Operations are rather quiet in best Yorkshire iron, though the trade is not in such an unfavourable condition as some people believe. Several weeks ago Messrs. Cooper & Co., of the Leeds Iron Works, gave their men notice to leave, and have now practically relinquished the manufacture of Yorkshire iron. But the decision has come as no surprise to the manufacturing community, for orders in best Yorkshire iron have been decreasing ever since Bessemer steel came into common use. Yorkshire iron, though used very extensively, is, after all, being driven out of the market by Bessemer steel, and this firm have consequently thought it best to discontinue operations. Still there are other concerns in and around Leeds who have adopted the manufacture of Bessemer, and converters are becoming gradually more numerous in the district. At the forges and foundries the men are well employed, and there is more railway work on hand than at the beginning of the year. The locomotive builders are busier, and for traction, pumping, and other engines the demand is more encouraging. Leeds makers of railway material are well supplied with work, and tyres, axles, and rails are selling with greater ease. Agricultural implements are on better call for the Colonies, though there is an unusually slow sale for them in the home markets. Cut nails, which have had such a prosperous market for months, are now rather a drug; but prices are on the whole maintained.

TEXTILES.—In spring goods there is a satisfactory demand, and most of the ready made clothing factories are busy. Attention is being turned to the sweating system in Leeds as well as in London; but it is contended, that however great the outcry, customers will go to the cheapest market, and that the public are really to blame.

NORTH STAFFORDSHIRE, 2ND MAY, 1888.

ENGINEERING.—There is no improvement noticeable in the general condition of the local engineering industry, and founders express themselves as very dissatisfied with current prices, which are, however, necessary to secure orders, owing to the keen competition which prevails.

THE IRON TRADE.—There are no additional demands forthcoming, and the mills and forges are working irregularly, making about four turns per week. The outlook is not an encouraging one, and there seems no probability of any improvement in price for the next few months. Deliveries of pig iron are being made on contracts entered into on quarter day, but in consequence of the inactivity at the forges a considerable quantity of pig iron is being put into stock. Of the thirty-nine furnaces in existence in this district, there are twenty-one now in blast. The Shelton Iron and Steel Company's new plant for steel making is approaching completion, and operations will probably be commenced next week.

SOUTH WALES, 2ND MAY, 1888.

TIN PLATES.—Notwithstanding that the recent extraordinary rise in the price of tin did not materially enhance that of plates, now that the tin ring has collapsed, and the metal is down at its normal figure, common sorts of tin plates can only find buyers at a reduction, viz., 12s. 9d. The nominal figure for Siemens quality with coke tinning is 13s., but orders are being freely booked at the lower figure. The value of "wasters" is a noticeable feature of the trade, fetching as they do in many cases the full price of the perfects. A company, with £50,000 capital, has been formed to take over the Gwendraeth Tin Plate Works, and Mr. Harries, of Pontymister, has been appointed manager. It is stated that the works are not to be started until the company can see their way to a profit of 1½d. per box. It is hoped that a return of the price of tin to its former value will shortly enable the company to commence operations, as the immediate district has greatly suffered since the closing of these works. Progress is being made with the building of the Victoria Tin Plate Works at Briton Ferry, a neighbourhood which has also suffered much since the iron works were closed.

NEW IMPORTS.—The first cargo of petroleum imported into South Wales has just been received by Messrs. Bird & Son, of Cardiff, who are arranging for the delivery of further cargoes periodically at that port. This firm also brought into Cardiff not long ago the first cargo of seal oil ever shipped direct to South Wales from Newfoundland.

BARROW-IN-FURNESS, 2ND MAY, 1888.

REVIVAL IN SHIPBUILDING AND ENGINEERING.—The anticipations of a permanent revival in the shipbuilding and engineering industries of this district are at length about to be fulfilled. In a few days the fact of large orders having been placed with the Naval Construction and Armaments Company, Limited, will be officially announced. In the meantime it is interesting to note that the preliminaries of work of very considerable magnitude have been arranged. It is certain that the local yard acquired by this new company will soon be very briskly employed, and that all the facilities at command for the building and engining of large steamers will be fully utilised. Further extensions of premises on a large scale have been decided on.

IRON AND STEEL.—There is a weaker tone to note in the iron and steel trade. The demand is much less active for iron, but makers are very busy, and are likely to remain so; indeed, they are fully sold forward for some months to come. The action of the holders of warrants in quoting less figures, in order to clear the stocks, has brought down prices, and 42s. 6d. per ton is now the quotation for parcels of Bessemer iron in mixed numbers. Makers, however, are not doing much business at this price, but are waiting until better prices can be obtained. Steel makers are very busy in all departments. Rails are largely sold forward, the mills are busily employed, and the output is well maintained. Prices have, however, gone down to £3. 17s. 6d. per ton net f.o.b. for heavy sections, and £4. 2s. 6d. for light sorts. In steel for shipbuilding purposes the demand is exceptionally strong, and very heavy contracts have been placed. In the iron ore trade business is steady but quiet, at from 8s. 6d. to 11s. 6d. per ton at mines.

MIDDLESBROUGH, 2ND MAY, 1888.

PIG IRON.—Stocks are decreasing and shipments are increasing, but prices continue to fall. It appears that the Glasgow speculators have the market under their control to such an extent that the ordinary economic law is powerless. No. 3 G.M.B. is now offered for 31s. 6d. per ton for prompt delivery. Makers, of course, hold to their price; but they cannot get it.

EXPORTS OF PIG IRON.—The exports of pig iron from the port of Middlesbrough for the month of April are greater than for some time past. They amounted to 90,641 tons, being 12,432 tons more than those of April, 1887, which had the highest record of the year. At this season the record is expected to be high, but this is certainly higher than was anticipated.

FINISHED IRON AND STEEL.—In manufactured iron there is hardly the same briskness that there was, and prices have, as a rule, dropped 2s. 6d. per ton. The works are busy, but there are few new orders to go on with when the present orders are completed. In finished steel prices are also easier, especially in plates, as there is not the same demand from the ship yards. The same trades union difficulty which troubled the N.E. Steel Works Company is affecting the Darlington Steel Company in exactly the same way. The manager has interfered with the right of the men to associate by dismissing the unionists, and the men have struck against this action.

SUNDERLAND, 2ND MAY, 1888.

SHIPPING TRADE.—The general condition of the market is satisfactory. Fixtures for Cronstadt are higher than those of last year, and a large amount of tonnage is engaged in very profitable employment in the Black Sea trade. During the last week the trade of the port was fairly satisfactory; 79,853 tons of coal were shipped, as against 75,925 tons in the previous week, an increase of 3928 tons, 30,031 tons being exported, and 49,882 tons sent coastwise. Other shipments comprised 1160 tons of patent fuel, as compared with 1946 tons in the previous seven days; 930 tons of lime, and 47,000 dozen bottles. Foreign imports included 29,205 sacks of wheat, 2298 bales of esparto grass, 2650 tons of iron ore, 483 tons of silver sand, besides a quantity of timber, block ice, and hay.

RIVER WEAR COMMISSIONERS.—The return for the month of March is scarcely so encouraging as it was for the early months of 1888, as in comparison with March 1887 there is a decrease in the total income of £391. 10s. 9d. The falling off in the river shipments of coal and goods traffic are answerable for the deficiency. The river shipments of coal show a falling off of 30,693 tons, but there is an increase of 13,103 tons in the coals shipped in the South Dock. Rapid progress is now being made with the new Roker Pier, and also with the new gates at the Gladstone Bridge. The depth of water at both entrances is satisfactory.

NEWCASTLE, 2ND MAY, 1888.

SHIPBUILDING.—The tonnage now building in the various yards on Tyneside may be approximately stated at 140,000 tons. Most of the shipbuilding firms have orders in reserve, but very few new orders are now being booked, and there is a probability that the present briskness in the yards will not be continued for a very lengthened period. The first wages dispute of any consequence which has arisen in this industry since business began to improve, commenced a week ago at Jarrow. About 400 platers struck work for an advance of 3s. per week on the present rate of 25s. Up to the time of writing no settlement has been effected. Work in this great establishment is now practically at a standstill, as progress in the other departments is prevented by the stoppage of the plating work. Messrs. Armstrong, Mitchell, & Co. have seven large vessels on the stocks at their Low Walker yard, and material is being received for several vessels that have not yet been laid down. Messrs. W. Dobson & Co. have received an order from Messrs. Milburn, of Newcastle, for a steamer of the largest class, and the frame work of this vessel has already been commenced. Messrs. Hawthorn, Leslie, & Co. have a large steamer, which has been built to the order of a local firm, nearly ready for launching. Messrs. Swan & Hunter will very shortly put a twin screw steamer off the stocks.

ENGINEERING.—Business at the marine engineering establishments could not well be more active, and in every instance night work is resorted to as the most effectual means of expediting contracts. The North-Eastern Engineering Company, Wallsend, are now engining the steamer "Rapel," which has just been launched by the Blyth Shipbuilding Company, and is owned by a firm at Valparaiso. Messrs. Palmer are also engining a vessel, and have another waiting its turn. Messrs. Clark, Chapman, & Parsons, Victoria Works, Gateshead, have just now a large amount of work in their steam winch, windlass, and steering gear departments; and some other firms that are engaged in the same lines are also doing well. Foundries are generally busy, and the manufacturers of ship and engine forgings have, in most cases, work enough to keep their furnaces and machinery fully employed.

BELFAST, 2ND MAY, 1888.

SHIPBUILDING AND ENGINEERING.—The ship yards still continue to be fully employed, and several orders for vessels of large tonnage have been placed during the past fortnight. There is at present a larger number of hands engaged in shipbuilding than there has ever been before. Wages are steady, with a slight upward tendency. It is rumoured that the Cork Harbour and Docks Company at Passage has been disposed of to a wealthy firm of shipbuilders; there is every facility, with the dry dock and convenient launching ground, for doing a large business. Most of the shipbuilding firms have forwarded handsome models of vessels, built by them, to the Glasgow Exhibition, and are preparing others for the forthcoming Irish Exhibition in London. Marine engineers and boiler makers are fully employed on both new work and repairs. Millwrights and iron founders are fairly busy, and some of the latter hold large orders. Messrs. Musgrave & Co., in consequence of their largely increasing business, have made arrangements for the erection of a large foundry at Bloomfield, near Belfast, for the manufacture of their patent stoves and stable fittings.

LINEN TRADE.—On the 27th April, Mr. Wm. Montgomery sold by auction the premises of the late Northern Spinning Company, Belfast. The entire mill and weaving factory was disposed of to Messrs. Ewart for the sum of £30,500. Trade still continues to be fairly good, but quiet, without any change in prices. The better numbers of yarns have had a slight upward movement, and find a good market. Tow yarns are somewhat easier. All the looms are fully employed. The general trade in hollands, canvas, &c., is up to the average, and prices remain as before. Damasks are in good demand, with prices slightly higher. In consequence of the fine quality of damasks now being turned out by power looms, the hand loom industry is rapidly declining. The manufacturers of fancy and hemstitched handkerchiefs, shirts, cuffs, &c., are doing a large and rapidly increasing trade.

THE "CYCLONE" DUST COLLECTOR.

Last week we had an opportunity of inspecting a "Cyclone" dust collector, as applied to wood working machinery, at the works of Messrs. A. Ransome & Co., Chelsea. The collector is an American invention, for the prevention of the escape of fine dust, which is often so troublesome in saw mills and other wood converting establishments. The efficient collection of chips and dust has also the great advantage of minimising the risk of fire. The principle of the collector which we are about

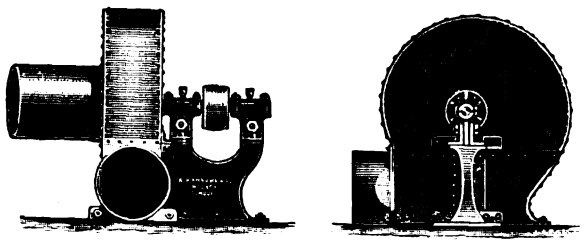

Fig. 1.

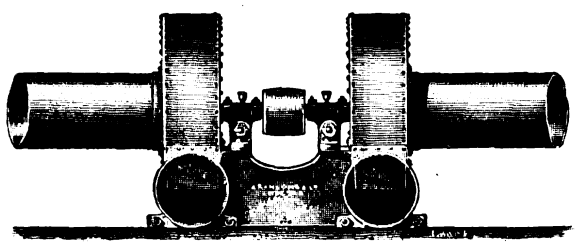

Fig. 2.

to describe as applied to wood working machinery, is also applicable to flour mills and other works where dust of all kinds has to be removed. At Messrs. Ransome's works the collector is established in conjunction with the well known pneumatic conductor system. We illustrate herewith the fans by which the light shavings and sawdust are drawn away from the wood working machines, and passed on to the collector. Fig. 1 shows a single, and Fig. 2 a double fan; while Fig. 3 is a part section of the collector. The sawdust and other particles of wood, after passing through the fan, are

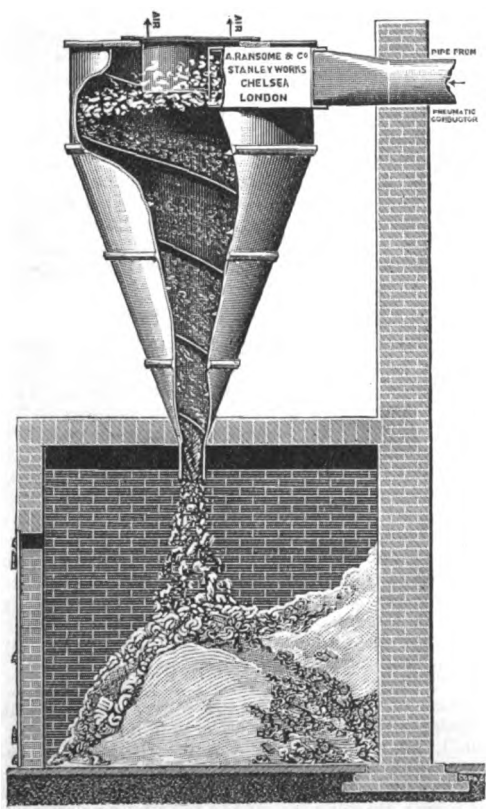

Fig. 3.

carried along the pneumatic conductor and enter the collector at its upper part, tangentially. The collector consists of a short cylindrical drum of galvanised iron, terminating in a cone, the point of which enters a chamber where the material is deposited. The drum is covered at the top by a plate with a central opening, through which projects a short pipe forming an outlet for the air. The interior surface of the cone is provided with a spiral shelf. The particles, as they are projected with great speed tangentially into the collector, are by this action of centrifugal force carried round the inner surface and acquire a spiral motion, and by the assistance of the shelf already mentioned are passed downwards into the chamber, the air escaping through the large central opening at the top. In cases where the sawdust and shavings are used as fuel for the boilers, the chamber can be dispensed with, and the material can be discharged directly into the stoke hole.

DIAGRAMS RELATING TO THE PROPERTIES OF WATER AND SATURATED STEAM.

II.

By Professor R. H. Smith.

(Concluded from page 426.)

Diagram II. gives expansion curves for gas and steam. There are three sets of curves, in each of which sets there are five curves, and in each of which the horizontal ordinate is the ratio of expansion. The first set of curves gives the ratio of the final or terminal pressures at the end of the expansion to the initial pressure for each grade up to 20. These ratios are given as percentages, the initial pressure being marked 100. These curves can be used either to find the terminal pressure for a given ratio of expansion, or to find the ratio of expansion required to reduce the pressure to a given terminal amount. The reason that they are carried out to so large a grade of expansion is to enable them to be used to find the volumes of the exhaust steam from an engine from the known ratio of back pressure to initial pressure. These curves are all marked with an F, the first letter of the word final; thus F(.....).

The next set of five curves is marked M (.....). These give the mean pressures for any given ratio of expansion, also in percentages of the initial pressure. This mean is, of course, reckoned from zero, there being no subtraction of back pressure. The mean effective pressure of an indicator diagram is different from this also because of the clearance volumes. The reckoning of the difference is shown below. It must be clearly understood that the mean pressure here tabulated is not that of the area under the expansion curve alone, but that of this area added to the area under the horizontal line showing the initial volume and pressure. In both these sets of curves the first portions lie so close together, and cut through the vertical lines so obliquely, that it is difficult to read them accurately. They are therefore plotted out again to a horizontal scale ten times more open. This more open scale is figured along the line marked A A. Throughout their range these curves should be used in preference to the others. The vertical scale of pressures for both these two sets is the same, and is marked F M at each end of the diagram.

The third set of five curves is marked W (.....). This gives the area referred to above, including that under the horizontal line; or rather it gives the ratio of this area to the area under the horizontal line alone, this latter being the value of the area without any expansion. The vertical scale for this set is different from that of the others, and is marked W at the two ends of the diagram. The ratio given here is the ratio of mechanical advantage obtained by the use of expansion without either clearance or back pressure.

To find the area of the effective indicator diagram, or the mean effective pressure for given clearance and given back pressure; let

c=ratio of clearance volume at one end to volume swept through by piston in one stroke;

$\frac{1}{r}$=cut-off, *i.e.*, ratio of volume swept by piston up to point of cut-off to whole volume swept through;

b=ratio of mean back pressure to initial absolute pressure.

Then real ratio of expansion is

$$r\frac{1+c}{1+rc}=\text{say } e.$$

On the proper curve W find the ratio corresponding to e, and call it w_e. Then the ratio of the area of the effective diagram to the rectangular area between the admission line and the line of zero pressure is

$$\left\{w_e(1+rc)-r(b+c)\right\};$$

and the ratio of mean effective pressure to initial absolute pressure is this divided by r, or

$$\left\{w_e\left(\frac{1}{r}+c\right)-(b+c)\right\}.$$

This latter is expressed rather more simply by

$$\left\{m_e(1+c)-(b+c)\right\},$$

where m_e is the mean pressure for real ratio of expansion e obtained from the proper curve M, divided by 100 so as to give it as an ordinary fractional ratio and not as a percentage.

Each of the expansion curves is drawn out to the formula:—

Final press. = Initial press. $\div n^{th}$ power of ratio of expansion where n is different for each of the five kinds of expansion.

If f represent the ratio of final to initial pressure and e the ratio of expansion, this formula is

$$f=e^{-n}.$$

If m represent the ratio of mean to initial pressure we have for the curves M ( )

$$m=\frac{1+\log_e e}{e} \text{ when } n=1$$

and $m=\frac{1}{n-1}\left(\frac{n}{e}-f\right)$ when n is different from 1.

If w represent the ratio of the area of the diagram up to ratio of expansion e to the area when $e=1$ (*i.e.*, area under initial horizontal line), we have for curves W ( )

$$w=m\,e=\frac{1}{n-1}\left(n-fe\right).$$

The following are the five cases of expansion tabulated with their values of n.

1. Hyperbolic or isothermal expansion of a perfect gas, marked H ..... $n=1$
2. Expansion of initially dry saturated steam with conduction of heat during expansion just sufficient to prevent condensation, marked S ... $n=1{\cdot}064$ =nearly $\frac{100}{94}$
3. Expansion of initially dry saturated steam without conduction of heat to or from the expanding steam, *i.e.*, adiabatic expansion, marked A S... $n=1{\cdot}135$ =nearly $\frac{100}{88}$
4. Adiabatic expansion of initially superheated steam, or steam gas, marked A S G..... $n=1{\cdot}304$ =nearly $\frac{100}{77}$
5. Adiabatic expansion of perfect gas, marked A G..... $n=1{\cdot}409$ =nearly $\frac{100}{71}$

THE PROSPECTS OF SOUTH STAFFORDSHIRE.

South Staffordshire has with other localities, though with greater severity, felt the extreme depression of the iron trade. Many causes have been assigned to explain why the district should feel more acutely than others the bad times of the past few years. For many years it has been declared to be "behind the times" in respect of scientific methods, and canal and railway companies have been abused, and perhaps with some show of reason, for the continued and severe depression. While very little has been done so far to remedy the excessive canal and railway rates under which the district suffers, it may be interesting to notice what manufacturers and managers have done to remove the dense commercial cloud under which they have so long existed. In its palmy days, before the discovery and development of the immense masses of ironstone in Cleveland, the West Coast, Northamptonshire, and Lincolnshire, South Staffordshire was probably considered the highest example of metallurgical industry. Men possessed of great energy, foresight, and perseverance were found ready to guide and improve its industries. From 1830 to 1860 considerable strides were made in the improvement of its manufactures. The substitution of round for square blast furnace hearths, increased dimensions in height and diameter of furnaces, together with the introduction of the hot blast, and the utilisation of furnace gases for heating purposes, all greatly augumented the prosperity of the district. These improvements resulted in a larger make of pig iron, economy of fuel, and diminished cost of production. When blast furnaces began to be built in Cleveland, South Staffordshire practice was considered so far perfect as to form the model upon which Cleveland furnaces were to be operated. Furnaces of 48ft. and 50ft. high, the type then generally employed in Staffordshire, were erected. Before many years elapsed Cleveland iron masters became aware, through the agency of the late Mr. John Vaughan and others, that to increase the height and capacity of their furnaces, to further increase the temperature of the blast employed, and to improve the methods of collecting and utilising the waste gases, gave them greater economy and increased production. However, the influence of progress is felt at last; and let us hope in time to save the iron industry of this famed district from extinction. It would seem that nothing short of an outlook of ruin has been sufficient to stir up some of the manufacturers

Advertisements intended for insertion in the current week's issue must reach the Manchester Offices not later than first mail delivery on Thursday morning. Scale of charges for displayed advertisements on cover and inside pages will be forwarded on application. Orders for single advertisements must be accompanied by payment in order to insure insertion, the charge for which is 2s. 6d. for the first four lines or under, and 6d. for each additional line; one inch and over at 7s. per inch; the line averages eight words. While all practical regularity in the insertion of serial advertisements will be observed, it can only be absolutely guaranteed in the case of those ordered to appear weekly.

All accounts are payable to the Publisher, JAMES F. BUTTERWORTH, *70, Market-Street, Manchester. Cheques should be crossed Manchester and Liverpool District Bank, King-street Branch, Manchester. Post Office Orders to be made payable at Manchester.*

With a Double-page Supplement, showing a
DIAGRAM RELATING TO THE PROPERTIES OF WATER AND SATURATED STEAM.

To Correspondents.

All communications intended for insertion in this Journal, or relating to Editorial matters, should be addressed to "THE EDITORIAL DEPARTMENT," *either at the Manchester or the London Offices, and must, in all cases, be accompanied by the name and address of the writer. No notice will be taken of anonymous letters.*

We cannot undertake to return manuscripts or drawings, and must request correspondents to keep copies.

Industries, VOLS. I., II., & III.

From July, 1886, to December, 1887.

A few Copies, handsomely bound in half calf, gilt lettered, may now be had at the Head Office, 70, Market-street, Manchester, Price 20s. each.

Industries:

FRIDAY, 4TH MAY, 1888.

INDUSTRIAL COMPETITION AND FREE TRADE.

AT the National Liberal Club last week, Sir Lyon Playfair opened a discussion on "Industrial Competition and Free Trade," in which he enlarged on some of the topics alluded to in our recent article (see *Industries*, page 401) founded on a paper by him on "The Progress of Applied Science, and its Effect upon Trade." He insisted on the point we have already mentioned, that the real cause of our depression could be summed up in a single sentence—that the world had not yet accommodated itself to the wonderful changes which science had produced in the modes of production and in the exchanges of commerce. If that be so, it strengthens the position we have all along taken in the matter of technical education, and proves that we require to train the rising generation, not only in the principles and applications of physical science, but also in those of political economy, combined with a thorough knowledge of what may be called the political geography of the part of the globe with which trade is being carried on. Too exclusive a devotion to science may end in industrial degradation and national disaster. As Professor Huxley put it some time ago, unless beneath all our scientific and technical education there is the strong moral fibre of healthy manhood, these will simply afford swifter methods of going to ruin. If Sir Lyon Playfair's opinions be correct, this is true not only individually, but also nationally; unless we study the improvements necessary for the distribution of the products of industry, improved industrial education will only add to the existing disorganisation.

Sir Lyon began his address by insisting that our long continued depression of trade had nothing to do with the fiscal policy of Free Trade; and he pointed out that in the United States, with a Protective policy, the unemployed had been more numerous and the labour disturbances greater than in England under Free Trade, and that the present depression was universal and synchronous in all machine using countries. Such periods of depression had been frequent; but the peculiarity of the present one was that it had lasted fifteen years, while the former depressions of the century had passed away in two or three years. The marked periods of depression in the United Kingdom have been in 1803, 1810, 1815, 1818, 1826, 1830, 1837, 1847, 1857, 1866, 1873, 1883, from which it will be observed that from the year 1837 to 1873 they were at tolerably regular distances of ten years. Since the latter date, with a short cessation for special industries in 1879-82, prices have maintained an abnormally low level; and this, in the opinion of Sir Lyon Playfair, as we pointed out in the article already alluded to, arises from the improvements which have been made in machinery, and by new inventions, which have produced great changes in the quickness and economy of distribution of commodities, and have profoundly altered the whole system of commerce. He maintained that since 1873 a great change has taken place both in commerce and manufacturing industry all over the world by scientific discoveries, as seen in the more economical use of steam, and the electric telegraph. The whole system of markets had been altered; to a great extent local markets had been destroyed, and the world itself had become the one market for all nations. The increased economy of transit had necessarily lowered prices, every ton of coal now carrying a much greater weight of cargo than it did a few years ago; while the improvements of machinery have increased the supply of commodities beyond the immediate demands of the world, and have too rapidly displaced the old forms of labour. The application of machinery demanded higher intelligence among the leaders of industry; but it was the essence of invention to displace unskilled labour, and its effect upon industry was, that while the labour of quantity, which was little more than brute force, was constantly decreasing in value as a factor of production, the labour of quality, or the labour carried on and directed by skilled intelligence, was as constantly increasing in value. All machinery and all invention tended to progress from simplicity to complexity, and therefore the workmen required a superior and versatile intelligence to be able to adapt themselves to the changes which constantly arose. Sir Lyon stated that in their last report the Inspectors of Factories mourned the fact that the labour of children in factories was decreasing; but this he looked upon as a happy sign, indicating an advance in the social condition of the people, for it proved that the labour now required more skill and intelligence than mere children could give to it, and as a consequence the labourers of low intelligence went to the wall, and flocked to large cities, and became familiar as the unemployed. Not only was this true of manufactures, but also of agriculture, the oldest and the most important of our industries. Agriculture was one of the few industries of a domestic character remaining in Great Britain, and our farmers had to meet in their isolation the competition of land cultivators in other countries, who carried on their industries through enlarged combinations, and with the use of machinery of the newest character. It was neither the climate nor the soil of England which stood in the way of our successful competition in food products; but the age of domestic manufacture was past, and English agriculture had now come under the common law of production. The conditions under which its products could be manufactured by combination and machinery had been established, and were in themselves of easy application. While willing to admit this, we must point out that people are beginning to see that there is still a very considerable field both for domestic manufactures and for the operations connected with farming. If things are made for use and not for sale, the workers are largely independent of foreign competition, and in agriculture, poultry, vegetables, and fruit might be raised to a much greater extent than at present; while many domestic industries might be cultivated by those who spend a great part of their time in idleness. Still, in the main, Sir Lyon Playfair's opinions are correct, and the world has become as one market for all nations.

The Fair Trade party would remedy matters by taxing imported goods which entered into competition with those produced at home, which, as Sir Lyon remarks, is much the same operation as when a person, dissatisfied with the working of a machine, adds a new cog, then a spring, then a lever, forgetting that, with every new addition, he is increasing friction and lessening power; and he is strongly of opinion that no fact in political economy is more clear than that taxation on foreign commodities must ultimately be paid by the consumers, and not by the producers. All taxation is a deduction

Digitized by Google

from the fruits of labour and from the fertility of the soil of the country imposing it. No political economist has ever been able to show how prices to consumers can be lowered by increasing the cost of production. He believes that the great industrial machine of this country is good enough in itself, but it needs proper oiling to make the parts work smoothly, and he is of opinion that the technical education of working men is the lubricant which we require. As we have very often pointed out, too much stress is laid on the education of the working men. While that is necessary, it is still more necessary that the leaders of the working men should be educated, or, at least, that every opportunity should be given for passing from the ranks to the position of commissioned officers. Sir Lyon seems to prove a little too much. The tendency of all labour is to become more mechanical, and while intelligence is necessary among the *hands*, the highest scientific knowledge is required for the *heads*. He, in fact, admits this when he says that Englishmen must prepare to keep the position of England in the increasing struggle of nations. They must give more of a trained intelligence to their producers, intelligence to the rank and file, and high technical education to the leaders of their industrial armies. He further insists, as we have always done, on the study of political economy, so that the workers may realise with tolerable certainty the conditions which regulate wages, and that both masters and men may be led to see that the interests of capital and labour are identical, and that the industrial prosperity of Britain is as much due to commercial freedom as the social condition of her people is due to political liberty.

TRANSFORMERS OR ACCUMULATORS?

The comparative merits of different systems of distributing electrical energy from a central station have been the subject of discussion amongst electrical engineers, and especially amongst the members of the Society of Telegraph Engineers and Electricians, for some months past. So far as the Society is concerned, the subject will now be laid aside; but individual electricians who may be called upon to decide for one particular system of distribution will not be much assisted by the lengthy discussions which have taken place at the Society. The subject in its present phase was first started by us in an article on the cost of central station lighting, which appeared in our pages on the 2nd December last. We there compared the installation cost, exclusive of building and land, for three different systems of distribution—one by storage batteries, the second by rotary transformers, and the third by alternating current transformers. The conditions of supply were in all cases assumed to be the same, viz., the same distance from the generating station, continuous service, and a maximum pressure of 100 volts in the houses; and under these conditions the first two systems came out almost equally costly, while the third system was found to be considerably cheaper than either. The question was further discussed in our correspondence columns, and in those of our contemporaries, until the matter was taken up by the Society of Telegraph Engineers and Electricians, to whom Messrs. Kapp and Mackenzie presented papers, the one on the construction of transformers, and the other on electric lighting by means of transformers. In the discussion on these two papers the relative merits of the rival systems were brought forward by their respective advocates; but the subject was by no means exhausted, for shortly afterwards Mr. Crompton contributed to *Industries* an article on the cost of central station lighting, which we published in our issue of the 16th March, and in which he endeavoured to show that the battery system was not more expensive, but far more efficient than the alternating current transformer system. This article was followed by a paper which Mr. Crompton read at the Society of Telegraph Engineers and Electricians on the 12th of April, and which led to a discussion lasting over three nights. It would be difficult to find a subject in applied science upon which so much has been written and spoken within the short space of four or five months; but we fear that, notwithstanding this vast amount of writing and talking, the practical question of central station lighting has been left very much where it was previously. It is certainly a significant fact that the small group of men who have in this country by far the greatest practical experience in distribution by transformers—viz., the engineers of the Grosvenor Gallery installation—have completely abstained from taking part in the discussion, and that in the face of a very determined attack on the part of Mr. Crompton, which was intended to prove that their system must be inefficient. Mr. Crompton, in fact, spoke of the consumption of coal at the Grosvenor Gallery installation as being so many tons per lamp in the daytime, and although this was obviously an exaggeration, the indictment was still sufficiently severe to induce the engineers in charge to refute it had they thought it worth their while to cross swords with Mr. Crompton on purely theoretical, not to say hypothetical, grounds. The engineers at the Grosvenor Gallery did, however, not think it worth their while to discuss the question; and whatever may be the theoretical objections of the advocates of the battery system to the low efficiency of the transformer system when the number of lamps is small, the broad fact remains that the Grosvenor Gallery station is doing an excellent business in selling electricity at 7¼d. per unit. The total number of lamps supplied from this station is at present about 28,000 10 c.p. lamps, and from an inspection of the plans of the circuits, we find that the area of lighting now extends southwards to the Thames Embankment, northwards to Marylebone Road, eastwards to Arundel-street, and westwards nearly to Hyde Park Gardens. At Deptford, machinery for the supply of 50,000 lights is now being erected; but this installation will eventually be very much enlarged, and it is intended chiefly for serving the City. These facts should be sufficient to convince even the most sceptical that the transformer system, whatever may be its theoretical disadvantages, is a great practical success.

The method of distribution advocated by Mr. Crompton is a combination of a five-wire direct supply system, with four local batteries. Its chief merit lies in the fact that the machinery need not be kept going during the hours of small consumption; but the limited pressure of 500 volts does not enable it to compete in point of distance with the alternate current system, where pressures of from 2000 volts to 2500 volts are employed, whilst it also violates the Board of Trade regulations, under which the maximum pressure on any conductor entering a house is limited to 300 volts. The last difficulty is to a certain extent overcome by the ingenious device of an earth connection midway between the extreme positive and negative ends of the circuit, and by the employment of lamps having one internal contact, which is always brought into connection with that wire on which the potential differs most from that of the earth. Mr. Crompton's system is, however, strictly speaking, not a storage system, because the supply in the busy hours of the evening must, as a rule, be simultaneously from the batteries and from the dynamos. It is true that the batteries are intended to give on an emergency the full output, but this is only for short periods. Now, the other battery system which we described in our article of the 2nd December, is strictly speaking a storage system, because each of the two batteries installed at the sub-centres is able to supply the whole of the demand whilst the other battery is being charged. This arrangement would of course be very much more expensive than the system advocated by Mr. Crompton, but it has the advantage of greater storage capacity. The merit of a high pressure system, say of about 2000 volts, is twofold. In the first place it enables us to locate the generating station on property of comparatively low value, without necessitating costly mains; and in the second place, as was pointed out by Mr. Preece, it makes it impossible for the local authority of the district lighted to exercise harshly the provisions of the Electric Lighting Act as regards compulsory purchase after the lapse of a certain number of years. It is obvious that no local authority would take over a central station if they could not work it profitably, and to do this they would have to secure not only the plant installed within their district, but also the distant generating station, and the right of way for the main leads. But as the generating station and a portion of the mains would be situated outside of their district, the purchase of the whole would have to be carried out on fair and equitable principles, so that the use of high tension currents is the very best possible guarantee to the investing public that their interests will not be set aside under a harsh Act of Parliament.

A great deal has been said during the recent discussions about the low efficiency of tranformers when working lightly loaded, and to overcome this difficulty Mr. Kapp proposes to switch off certain transformers during the hours of minimum demand, so that the remaining transformers may be used with a fairly large output, and may therefore work with high efficiency. It is, however, necessary to bear in mind that the switching out of transformers could not conveniently be done from the central station. It is necessary to switch off, not only the primary current, but also to interrupt the connection of the transformer with the secondary or distributing network, and this could only be done from the central station if some more or less complicated device were adopted by which the secondary current is automatically switched off as soon as the primary feeder has been switched off at the station. Such automatic appliances are in themselves objectionable, and it would probably be necessary to switch off both currents at the transformers themselves, for which purpose an employé of the company would have to visit the sub-centres at stated hours in the day. It is very doubtful whether the gain thus obtainable is sufficient to pay for the complication of the service thereby entailed. The experiments of Professor Ayrton in England and of Professor Forbes in America have shown that the efficiency of a transformer at full output is about 95 per cent. The loss of five out of every hundred horse power given off by the transformer may be roughly divided into 3 h.p. lost in heating the iron, and 2 h.p. lost in heating the copper. The loss in the iron is constant, so that, even if a 100 h.p. transformer is doing only 3 h.p., another 3 h.p. would have to be wasted in heating its core. The loss in copper heat at this low output may be neglected, so that the efficiency would be 50 per cent. In a station arranged for a maximum supply of 10,000 lamps the power required at the time of heavy lighting would, according to American practice, be about 1000 h.p., giving ten lamps per horse power. Supposing that only 3 per cent. of the lamps were lighted during the daytime, the power required at the station would be 60 h.p., or five lamps per horse power. Now, it will readily be conceded that the difference between 30 h.p. and 60 h.p., that is, the loss of 30 h.p., which is due to the low efficiency of transformers when these are very lightly loaded, is but a small matter in a station which at times develops 1000 h.p., and the annual coal bill would, therefore, not be materially affected by a falling off in efficiency during the daytime. It must also be remembered that as the efficiency of transformers becomes lower, that of the distributing plant increases. It is on account of these various reasons that transformer lighting, although theoretically not perfect, is yet a great practical success.

THE EDISON GLOW LAMP PATENTS.

We now continue our report of this important case from page 428 of our last week's issue. Sir Horace Davey, in his opening speech for the defendants, which occupied almost the whole of one day, pointed out that Lane-Fox's patent, taken out in October, 1878, contained a statement of the principles which lie at the bottom of a successful incandescent lamp to be used in a system of parallel distribution. It was there stated that the lamp must have a high resistance, and that the electromotive force must be considerable, say about 100 volts. A subsequent specification of Lane-Fox's was also referred to, which came very near to Edison's, except that Lane-Fox, instead of saying "I make use of carbon," had stated that he used certain metals "or other suitable material." Sir Horace Davey then passed on to the consideration of Swan's anticipations, and said that he hoped to be able to prove, that from as early a date as 1877, but certainly from 1878, Mr. Swan was engaged at Newcastle, with the assistance of Mr. Stearn, at Rockferry, near Birkenhead, in making incandescent lamps, and that he succeeded in making not only lamps with straight conductors, which had been called "stick" lamps, but also lamps with more or less filamentous conductors, in some cases made from carbonised paper. Speaking of the "stick" lamp which was produced in Court by the Edison Company, the one frequently exhibited by Swan at lectures before the date of Edison's patent, Sir Horace said: "It cannot be denied, and I think it never has been denied, that this lamp is identical with Edison's specification, unless you can distinguish it on the ground that this carbon conductor does not come within the description of what Edison meant by a filament." It had been said by the plaintiffs that it was a lamp of low resistance, 3 to 5 ohms, and no doubt it was so, although its exact resistance could not now be ascertained, for after a "litigious" life of ten years, the carbon had become damaged. The lamp was composed of a straight stick of carbon about 1¼in. long and $\frac{1}{25}$in. diam., mounted between two platinum wires in a glass globe, from which the air had been exhausted. The globe of the lamp was considerably dimmed in the inside by deposited carbon. The occluded gases had not been removed by Mr. Swan when he constructed the lamp in 1879. Sir Horace Davey then proceeded to point out the main lines of attack which he proposed to make on Edison's specification. He said that Mr. Edison had not on his specification added anything to the stock of knowledge possessed by the public in 1879; that Edison had not given sufficiently clear and definite instructions to enable a skilled working man to make a lamp without a considerable amount of experimenting; that he had in fact done nothing more than make a series of suggestions which he had not worked out in his own mind, but which he had left to be worked out by subsequent experimenters; that the mere statement that a combination of a carbon filament

Digitized by Google

within a receiver entirely of glass through which the leading wires pass, and from which receiver the air is exhausted (Edison's second claim), was nothing more than a statement of a desirable object which electricians had in view. Sir Horace then went on to discuss the meaning of the word "filament," and pointed out that the witnesses who had been called for the plaintiffs had been unable to give anything like an accurate definition of a filament, and would not commit themselves by stating where a filament ended and a pencil began, and he should argue that Edison had deliberately abstained from making his meaning clear, and that a patentee was rigorously bound in law to put up such a fence that everyone coming within that fence would be coming upon forbidden ground, and Edison had erected no such fence. Sir Horace then dwelt on the fact that, with the exception of a few lamps made for use in the former action against Messrs. Woodhouse & Rawson, and for use in this action, the plaintiffs had not been able to produce a single lamp made according to the directions given in Edison's specification without the addition of any other processes or improvements, although the counsel for the plaintiffs and their scientific witnesses had spoken of the world wide Edison lamp which had created a revolution in electric lighting. Edison himself had taken out several subsequent patents, in two, at least, of which he had given further instructions in the processes of manufacture. In one of these he had stated that purely structural carbon was the only carbon which would answer; which, said Sir Horace, is the greatest possible condemnation of that portion of the specification in question which described and claimed filaments made by carbonising lamp black and tar. He then proceeded to cite certain decided cases, which, he contended, showed that Edison's specification was invalid. Sir Horace Davey then went to the other patent upon which this action has been brought, viz., Cheesbrough's, which is a patent for an invention made by Messrs. Sawyer and Mann, in America, and communicated by them to Mr. Cheesbrough in this country. The invention consists in placing the filament in a vapour of some hydrocarbon, and then passing the electric current through it, so as to raise the conductor to a yellow heat. At that temperature the hydrocarbon is decomposed, and carbon is thrown down in a very beautiful manner upon the filament, the deposition taking place most rapidly at those points on the filament where the temperature is highest, which are the places where the filament is thinnest. By this means a filament of uniform electrical section is rapidly obtained. Sir Horace Davey stated that the anticipation upon which he intended to rely chiefly was a paper published by the eminent French chemist, M. Despretz, many years ago. M. Despretz had been anxious to ascertain whether he could fuse or volatilise carbon. He had placed carbon in the electric arc, and he had also passed a current of electricity through the carbon, and in the course of his experiments he had surrounded the carbon with nitrogen; but he found that some chemical action took place between the carbon and the nitrogen, and he then hit upon the idea of placing the carbon in a hydrocarbon atmosphere. To his astonishment the hydrocarbon was decomposed, and carbon was deposited not only on the piece of carbon operated upon, but also on the clamps in which it was held, and on the glass vessel containing them. Sir Horace also stated that he intended to rely upon that passage in Cheesbrough's specification in which he stated that his invention was not confined to carbon alone, but included many other substances which are infusible non-conductors, as for example lime.

Mr. Robert Percy Sellon, the chief electrician of the Anglo-American Brush Company, was the first witness called for the defendants. He was examined by Mr. Finlay, and described at full length the process by which the Brush Company had made the lamps complained of. That process, which is to some extent covered by patents, consists in taking cellulose in a pure condition and dissolving it in chloride of zinc, producing a jelly-like substance, which is forced through a small circular aperture into alcohol. The effect of the alcohol is to cause the cellulose to deposit in long fine homogeneous threads, which are very carefully dried on velvet, and then wound upon moulds the shape of the filament when finished, and the whole placed in carbonising crucibles, packed with charcoal, and raised to a high temperature, care being taken to exclude the atmosphere, and to allow for the contraction of the filaments during the process of carbonisation. The filaments are then mounted in clips and flashed for a few seconds only, so as to bring them all to the required resistance, or, as it is termed, to standardise them. The filaments are next mounted on to the platinum wires, by again flashing the surfaces where the carbon and platinum touch, and are then ready for mounting in the lamp and for having the globes exhausted and the occluded gases taken out, the vacuum which is obtained being a very perfect one. Mr. Sellon was examined at some length as to the insufficiency of the directions contained in Edison's specification, and more especially as to the carbonising, and the injurious effect alleged to be produced on the platinum leads by putting them into the carbonising chamber in those cases where the filaments are mounted to the platinum before carbonising. Mr. Sellon was then cross-examined by Mr. Aston, and admitted that in one or two of the papers in evidence in the case there were directions given for putting powdered charcoal into the crucible when carbonising carbons to be used for arc lighting, especially in a description of the process adopted by the well known French maker, M. Carré.

The next witness was Professor Crookes, who was examined by Mr. Graham. He described very minutely a large number of experiments which he had made upon the directions contained in Edison's specification, and which he had found the greatest difficulty in following, having failed to produce a lamp of any commercial value by any of them. Professor Crookes also described some very remarkable experiments which he had made upon that portion of Edison's specification where it is stated that the filament may be coated with some non-conducting non-carbonising body. Professor Crookes coated the filament with asbestos, fire clay, and other similar substances, and found that at temperatures below those which are usual in a lamp, a chemical reaction takes place between the carbon and the oxygen in those substances, the carbon burning off as carbonic acid. Professor Crookes had also made similar experiments with respect to the passage above referred to in Cheesbrough's specification. He took a small pencil of carbon, and surrounded it with lime, and passed the current through the carbon, while it, with its lime envelope, was surrounded by a hydrocarbon gas. Carbon was deposited throughout the pores of the lime. The witness then cut a small pencil out of the lime, impregnated with carbon, and mounted it in a lamp, which was then exhausted. When the vacuum was as good as that usually obtained in lamps, Professor Crookes passed the current through, and before the usual lamp temperature was reached a reaction commenced. The filament began to scintillate, and broke down immediately. Experiments of a similar character were made with magnesia and other bodies with similar results.

Professor Crookes was cross-examined at great length by the Attorney-General, and admitted that many of the references in Despretz's experiments were made with the arc phenomena and not with incandescent carbon.

We shall report the further progress of the case in our next issue.

THE SOCIETY OF TELEGRAPH ENGINEERS AND THE LATE MR. T. R. CRAMPTON.

At the meeting of this Society, held on the 26th inst., the President (Mr. Graves) announced the death of Mr. T. R. Crampton, member, and called on Sir Douglas Galton, as an intimate friend of the deceased, to move a resolution to the effect that an address should be presented to his widow and family expressing the sympathy and condolence of the Society with them in their bereavement. In moving the resolution, Sir Douglas Galton referred to Mr. Crampton's work in the early days of railway enterprise, and his invention of the "Crampton engine," which is still in use in France on the Chemin de fer du Nord. He reminded the younger members of the Society that the first successful submarine cable laid between Dover and Calais was due to Mr. Crampton. Earlier attempts had been made with cables consisting simply of a wire covered with insulating material, but they had not been successful. It was Mr. Crampton who devised the cable of 1851, which formed the model for all subsequent successful cables. He retired somewhat early from active engineering enterprise to undertake contract work, and this was shortly followed by his retirement into private life. He did not, however, abandon his interest in engineering works; and among other things he devised hydraulic machinery intended to be used in excavating a Channel tunnel, and he actually employed the method in excavating a tunnel near Sevenoaks, making use of the waste water in removing the excavated materials. Professor G. Forbes seconded the resolution, which was unanimously agreed to.

Letters to the Editor.

PROPOSED EXTENSION OF TEXTILE MANUFACTURES IN IRELAND.

To the Editor of "Industries."

Sir,—Although cotton spinning about fifty years ago formed one of the chief manufactures in Ireland, it has, unfortunately, from various causes, now become almost entirely extinct. The great prosperity attendant on the introduction of machinery into the flax manufacture while the cotton trade was passing through a season of depression, was the means of enticing many producers to discard the latter and adopt the former manufacture; while other concerns, which were endeavouring with worn and antiquated machinery to compete with the well equipped factories of Lancashire, were, as a consequence, forced out of existence. In this way, each year saw a diminished production of cotton yarns in Ireland, until, at the present time, the trade is represented by only two concerns of any magnitude, one of which is engaged in the fine trade. In the official returns to the Home Office, the extent of the cotton industry in Ireland is given as follows: No. of spinning spindles, 68,604; No. of looms, 2501.

That the position and climate of Ireland is of the most favourable character for cotton spinning is generally admitted; and, but for the disturbed condition of the country, we may conclude that English and Scotch capitalists who are on the look out for new fields of enterprise would, ere this, have made use of the advantages thus offered for the re-introduction of this dying manufacture on a large modern scale. In the North of Ireland, however, if our capitalists would only realise the fact, there is little to stand in the way of successfully establishing one branch of cotton spinning, and it is with the idea of showing them that such is the case that I now take up this important subject. Before, however, proceeding to that part of it which deals directly with this point, it may be well for me to give here the following explanatory remarks on the two systems of spinning now adopted in English mills, viz., ring and mule spinning.

In the United Kingdom at the present time there are estimated to be 40,000,000 spindles distributed throughout our cotton spinning concerns, of which about 36,000,000 are known as mule spindles, the remaining 4,000,000 being made up of throstle and ring frame spindles. The reason or cause of the disparity in numbers between the latter and the former is due to the fact that the ring frame, although not a new invention, has only been recently introduced to the trade, while the self acting mule has been in general use for nearly a half century. The great distinctive feature about the two machines is that the ring frame is continuous, while the mule is intermittent in its action of spinning; consequently the production is much greater by the former than by the latter machine. To explain this more clearly, I may state that the self acting mule is constructed of two distinct parts, viz., a stationary beam and head stock, and a traversing carriage. The material as it leaves the rollers passes to the revolving spindles fixed in the carriage, as it recedes from the beam, and after the length of its traverse has been reached the twisting and the delivery ceases, and the winding on of the threads begins, during which the carriage is drawn up to its original starting place. In the throstle and ring frame, delivering, twisting, and winding are effected simultaneously. In the throstle frame, however, owing to the spindle being weighted with a flyer, the number of revolutions at which it can be driven is limited, so that the production is little in advance of the mule, and accordingly machines of this class are not now being made. It is only during the past few years that the subject of ring as against mule spinning has been energetically taken up and practically tested; but the result has so far been in favour of the former system, at least for the spinning of the lower numbers of yarns. This fact may be, and is, disputed by some; but there need be little difference of opinion on the subject, as in numerous concerns where both ring frames and mules were in operation, the latter have given place entirely to the former machines. The advantages claimed for the ring frames over mule machinery may be briefly summarised as follows: (1) A ring spindle will easily produce 25 per cent. more than a mule spindle. (2) The yarn produced from rings is more regular, and very much stronger than that spun upon mules. (3) There is no cop bottom waste made with ring frame yarn. (4) Young persons can learn to work the ring frame with greater facility than the mule. (5) The ring frames are worked by females, while mules require the attendance of men. The attendants' wages, therefore, are much lower. (6) There is less danger from fire, as there is less friction. (7) The cost of repairs with ring frames is about 75 per cent. less than with mules. (8) There is greater economy in oil. (9) There is also economy in space, as fifteen ring frame spindles only occupy the same area as eight mule spindles. (10) There is less shafting and gearing required.

Against these advantages, however, must be taken into consideration the fact that the cost of the two machines, spindle for spindle, is greater in the ring frame than in the mule, and also that the yarn on a ring frame requires to be spun on a bobbin or tube, while the mule yarn is built up on the bare spindle. Probably a mule spinning mill in Lancashire can be built at the present time for about 21s. per spindle, while a ring mill will cost from 24s. to 25s. per spindle. This greater first cost is, however, of small moment when compared with the greater production and less working cost of the ring frame. As I have just stated, it is also against the ring frame that the yarn requires to be wound on a bobbin or tube, which, of course, increases the cost of production, and carriage or freightage of the yarn. These drawbacks are, however, more than accounted for by the greater advantages which a ring pirn possesses over a mule cop, and which may be enumerated as follows: (1) All the yarn made upon a ring frame can be utilised. A mule cop has always more or less yarn wasted in the cop bottom. (2) With a ring pirn there is no "readying" or "clearing" of the cop nose required, as all the yarn is built straight and regular, and will leave the pirn from beginning to end without waste, and very seldom breaking from the commencement to the finish of the unwinding operations. On the other hand, in mule cop yarn there is always a certain amount of "readying" or "clearing" necessary when the cop is fixed on the winding frame skewers or the shuttle peg, and in addition mule yarn is more liable to break than ring yarn in weaving. (3) Sometimes mule cops are "stabbed" by the winders and weavers, but in a ring frame pirn this cannot possibly happen.

For some time past at the quarterly meetings of Lancashire shareholders the subject of discarding the mules and replacing them with ring frames has been often discussed. This is owing to the fact that the few ring frame spinning concerns which have been floated within the past year or two, have succeeded in declaring dividends ranging from 8 per cent. to 10 per cent., while mule mills, built at the same time on the most productive and economic principles, can scarcely show dividends of half the above value. In Scotland, France, Germany, and America the ring system of cotton spinning is also proving remunerative, and consequently making rapid progress, so that taking into consideration the facts that the Belfast district possesses the

Digitized by Google

very highest commercial advantages, that the climate is specially suitable for the cotton manufacture, and that there is an abundant supply of unemployed labour, the subject of ring spinning mills is one well worthy of consideration.

To erect a ring spinning concern in Belfast, say of 40,000 spindles, and preparation machinery, with all the necessary engines, boilers, shafting, and gearing, a share capital of £60,000 would be necessary, augmented by a loan fund of £20,000, which could be raised at say 4 per cent. If this were accomplished, then of a share capital of say 12,000 £5 shares, or 6000 £10 shares, it would only be necessary to call up about £2. 10s. or £3 per share, equal to about £30,000 or £36,000. As a considerable portion of the capital would, no doubt, be raised in England and Scotland, the division into £5 shares would be the most popular, and receive greater favour at the hands of intending investors. Of course this would be a matter entirely for future consideration. The cost of erecting a mill of this size in Belfast I estimate at £56,000, which would include the building, driving power, preparatory and finishing machinery of every kind, all on the most modern, productive, and economic principles of construction. The production would, of course, depend on the counts or numbers of the yarn; but to take an average, say 30's, 42,000lb. would express approximately the net weight of yarn turned off weekly. The necessary cotton supply could be obtained from Liverpool at a slightly cheaper rate than from Liverpool to Oldham or Bolton, so that therefore, in this respect even, Belfast would be better placed than the great centres of the Lancashire cotton trade. A mill of this size in Belfast, under proper management, could not possibly fail to be a great financial success, and pay a return on the invested capital of from 12 to 15 per cent., and possibly even higher, as will be explained from the following tabular statement, contrasting the wages in a Lancashire mule mill of say 50,000 spindles (equal in production to 40,000 ring spindles) to a Belfast ring spinning concern of the capacity already stated:—

Comparison of the Weekly Wages in a Lancashire Mule Mill having 50,000 spindles, and a Belfast Ring Mill having 40,000 spindles.

	Lancashire. £ s.	Belfast. £ s.
In mixing room—		
Three attendants required...combined wages	1 15 ...	1 6
In scutching room—		
Six attendants required..... „	5 0 ...	4 0
In carding room—		
Carder, £2. 10s.; under carder, £1. 10s.; and a grinder, £1. 2s... „	5 2 ...	5 2
Seven other grinders ..... „	7 7 ...	5 12
Four card tenters ..... „	2 12 ...	1 12
Ten drawing frame tenters ..... „	9 0 ...	5 10
Seven slubbing frame tenters ..... „	6 6 ...	3 17
Six intermediate tenters..... „	5 8 ...	3 6
One intermediate tenter.....	0 14 ...	0 8
Four back tenters ..... „	1 8 ...	1 4
Sixteen rove frame tenters ..... „	14 8 ...	8 16
Eight back frame tenters ..... „	2 16 ...	2 8
In spinning rooms—		
Twenty-five spinners for mules (men)	50 0 ...	—
Fifty piecers for mules, at 12s. 6d. each on average	31 10 ...	—
Eighty ring frame tenters (women).....	— ...	44 0
Eight back tenters.....	— ...	2 8
For working engine, boilers, packing, &c., cost at Belfast would, at very lowest estimate, be £4. 11s. under that of Lancashire	4 3 ...	—
Totals	147 9 ...	89 9
	89 9	
Weekly balance in favour of a Belfast ring mill.....	58 0	

From the above statement, then, it will be seen that in wages alone there would be a saving of £58 per week, equal to £3,016—or say £3,000 per annum—a sum which would in itself be sufficient to pay the loan interest of 4 per cent (£800), and a dividend of 7½ per cent. on a called up share capital of £30,000. To this estimate must be added that of a Lancashire ring spinning concern, which, if I take at 8 per cent., after making allowance for depreciation, &c., will give a total dividend available for distribution of 15½ per cent.

As regards the greater productive capacity of the ring frame, the following statement, obtained from the working of machines erected within the past three years, may be interesting:—

Counts or Nos. of yarn.	Production of mule in hanks, per spindle.	Production of ring frame in hanks, per spindle.
20's	32½	44
24's	31	41
28's	29	39
30's	28½	38½
32's	28	37½
36's	27	35
40's	26	33
42's	25½	32

Before concluding this already long letter I would like to refer to another very important advantage which a ring frame concern in Belfast would possess. At the present time there is a large quantity of cotton yarn being consumed in Belfast and the neighbouring manufacturing towns, both in cotton and linen weaving factories. The numbers of these yarns, I find, range from 150's down to 10's; but as the different kinds are not specified in our import returns (the gross weight in tons merely being given), it is difficult to arrive at a decision of how much of this comes within the range of ring spinning. The counts or numbers which a ring frame is economically adapted to spin is limited to 50's, but 45's, or even lower counts, is considered more satisfactory. From extensive inquiries I have made, I have been led to believe that about two-thirds of the total import of cotton yarns would come under the ring frame capacity; but allowing that only half were of this description, then the requirements of our northern manufacturers alone could not be supplied by the total production of a ring mill of the size I have now been considering. For during the year 1885 there was imported into Belfast 5,022,080lb., or an average of 96,578lb. weekly; and during the year 1887 the import has been 5,800,000lb., or an average of about 111,000lb. weekly. If, then, I take 50 per cent. of these quantities as representing yarns which might be produced by a Belfast ring concern, I find that it would require about 56,000lb. weekly to supply the demand. As a mill of 40,000 spindles could only turn off say 40,000lb. of yarn weekly, there would therefore be ample scope for its encouragement and development. The cost of transit of yarns from Manchester, Oldham, and Bolton to Belfast being almost ¼d. per lb., there would therefore, from this item alone, be a saving to a local concern of about £42 weekly, or over £2,100 per annum, which in itself would be sufficient to pay about 7 per cent. on the share capital, or an aggregate dividend equal to about 22 per cent. This estimate can be formed on another basis, so that one will form a check upon the other. In Lancashire mule mills at the present time the margin of profit realised on the spinning of say 26's twist yarns, after paying every item of expense, and making allowance for depreciation, &c., averages from 1/16d. to ⅛d. per lb. In ring mills this margin varies from 1/16d. to ⅜d. per lb. To test, therefore, whether the results already given would be borne out by this statement, I give the following calculation: I will take the difference in wages between a Belfast ring concern and a Lancashire one as £45 per week, and I have thus a saving of £2,340 per annum. To this I must add the profit on the production of 40,000lb. weekly, which, if I take at the lowest figure, *i.e.*, 1/16d., would amount to £52 weekly, or £2,704 per annum, making a total of £5,044, or say £5,000. If from this sum I deduct the interest on the loan capital, viz., £800, I have then a disposable balance of £4,200, which would be sufficient to pay a dividend on the share capital of 14 per cent. Adding to this the percentage made up by the saving in carriage, viz., 7 per cent., and I get a total return of 21 per cent. Of course there would necessarily be greater expenses in connection with the directorate and the management of a concern in Belfast than in Lancashire; but I may safely assume that a well and economically conducted ring spinning factory should be able to pay at least 14 to 15 per cent. As I have already stated, workpeople are plentiful in the Belfast district, and there is one great advantage which would be derived by a ring spinning concern, viz., that flax spinning mill hands could, almost in a day's time, be initiated into the working of the cotton ring frame.

The task I have had before me for some time is now completed, and I shall be pleased if this letter is the means of interesting Lancashire capitalists in the question. That all the statements I have made are thoroughly reliable I can fully prove, and I may say that I shall at any time be happy to give any further information on the subject that may be required.

Yours, &c.,

Belfast, 28th April, 1888. HUGH MONIE.

SHIPBUILDING NOTES.

ON the 14th ult. a steel sailing barque named the "Lorton" was launched by Messrs. Workman, Clark, & Co., Limited, Belfast, for Messrs. P. Iredale & Son, Liverpool. Her dimensions are: Length, 241ft. 8in.; breadth, 27ft. 4in.; tonnage registered, 1360 tons.

On the 19th ult. there was launched from the Low Walker Shipbuilding Yard of Sir W. G. Armstrong, Mitchell, & Co., a steel twin screw steamer, for service on the Caspian Sea. The vessel, which is named the "Yang," is of 500 tons burthen and 180ft. long, and on her arrival at St. Petersburg will be divided so as to pass the canal locks. A portion of the holds of the "Yang" are fitted up for carriage of petroleum in bulk, and her bunkers are also arranged for carrying liquid fuel, with which object the main boiler and donkey boiler will also be fitted with a special apparatus for burning petroleum refuse or astatki, which is practically the only fuel now used on the Caspian Sea.

On the 23rd ult., Messrs. Edward Withy & Co. launched from their yard at Hartlepool a steel screw steamer, named the "Grenville," built to the order of Messrs. J. Holman and Sons, London. She is 260ft. by 35ft. by 18ft., and built throughout of Siemens-Martin steel; has a long raised quarter deck, long bridge house, and a topgallant forecastle main, bridge, quarter, and topgallant decks, skylights, bulwarks, rails, bulkheads, cargo battens, &c., being built of steel and iron; is constructed with a cellular double bottom (Withy & Sivewright's patent), all fore and aft, and is fitted with four steam winches, two donkey boilers, and patent windlass fitted on forecastle, hand and steam steering gear amidships, and patent screw stand-by gear aft. The accommodation for officers and passengers is under the poop aft, and is fitted up in hardwood. The panels in the sides of the saloon are handsomely painted in oils by the lady decorative staff of the firm, and considerable taste has been shown in the selection of the different subjects painted. The accommodation for the engineers is fitted up in a neat and comfortable style in the bridge, and the crew and firemen are berthed under the topgallant forecastle. The steamer is rigged as a two-masted fore and aft schooner, with iron lower masts, and is built to the 100 A1 class at Lloyd's, under the personal superintendence of Captain Holman. She will be fitted with triple expansion engines by Messrs. Blair & Co., Stockton-on-Tees, under the superintendence of Mr. E. J. Caiger.

On the 24th ult., the steel screw steamer "Zeta" was launched from the shipbuilding yard of Messrs. Jos. L. Thompson & Sons, North Sands, Sunderland. The vessel has been built to the order of Messrs. Turner, Brightman, and Co., of London. She is 3400 tons dead weight capacity, and of the "well deck" type, having raised quarter deck, hurricane house, and topgallant forecastle. She is to be classed 100 A1 at Lloyd's. The "Zeta" is now being fitted with engines of the triple expansion type and 200 n.h.p., and with boilers by Messrs. Blair & Co., Limited, Stockton-on-Tees.

On Wednesday, the 25th ult., Messrs. Russell & Co. successfully launched from their Greenock yard a large steel screw steamer, built to the order of a Liverpool firm. Her dimensions are: Length, 320ft.; breadth, 40ft.; depth of hold, 27ft. 6in. The vessel is classed 100 A1 at Lloyd's, and is built to the Admiralty requirements of a troopship. She has a dead weight capacity of nearly 4200 tons. The engines will be supplied by Messrs. Dunsmuir & Jackson, of Glasgow, and have cylinders 24in., 39in., and 64in. diam., by 45in. stroke. There are two double ended boilers of large size, each having six Brown's patent furnaces. The construction of the vessel and her machinery has been superintended by Messrs. Flannery & Blakiston, of Liverpool.

On the 26th ult., there was successfully launched from the shipbuilding yard of Messrs. William Simons & Co., Renfrew, a handsomely modelled screw steamer for passenger service on the Adriatic. Its dimensions are: Length, 157ft.; breadth, 21ft.; depth, 11½ft. The vessel is built of Siemens-Martin steel, under the superintendence of Lloyd's special survey. Saloon accommodation is provided at the after end for first class passengers, having ladies' cabin, lavatories, &c., and the panelling is of well selected birdseye-maple, pilasters and mouldings of mahogany, and cushions of Utrecht velvet. A second class saloon is placed under the main deck forward, and has sleeping accommodation for twenty passengers. Deck shelter for third class passengers is provided under the turtle back forecastle. Electric light is fitted in the various cabins, engine room, &c., and also for side lights. The engines are on the triple expansion principle, and are expected to propel the vessel at a high rate of speed. The boilers are constructed of steel for a working pressure of 150lb. per square inch. As the vessel left the ways, she was named the "Trieste C."

Messrs. Cochran & Co., steam yacht builders, of Birkenhead, launched from their Bidston wharf, on Thursday, the 26th ult., a steam yacht of the following dimensions: Length over all, 117ft.; length on water line, 106ft.; beam, 17ft.; depth, 10ft. 8in. She has been built to the order of Mr. Frederick Platt, Barnby Manor, Newark, and was designed by Mr. St. Clare J. Byrne, of Liverpool. She is fitted with triple expansion engines, having cylinders 11in., 17in., and 28in. diam. respectively, and 20in. stroke.

Messrs. Scott & Co., of Greenock, launched on the 27th ult., the twin screw steel steamer, "Sung Kiang," 1650 tons net register. The vessel has been built to the order of the China Navigation Company, and will be fitted with engines of triple expansion type, indicating 1000 h.p.

On Saturday afternoon, the 28th ult., there was successfully launched from the yard of Messrs. Wm. Doxford and Sons, Pallion, a handsome new screw steamer, "Brenner," built to the order of Messrs. Cag, Hall, & Co., of South Shields. The vessel is intended for the general trades, and is entirely built of steel to Lloyd's 100 A1 class. The principal dimensions are: Length between perpendiculars, 265ft.; breadth, 37ft.; depth moulded, 18ft. 6in.; with cellular bottom fore and aft. The vessel carries 2600 tons on 18ft. The engines are of the triple expansion type, and are supplied with all Messrs. Doxford's latest improvements; the cylinders are 20in., 33in., and 54in. diam. respectively, and the stroke 36in. She is fitted with Bow-McLachlan's patent steam steering gear, Hastie's screw gear aft, four steam winches, by Messrs. Welford Brothers, of Pallion, patent multitubular donkey boiler, by Messrs. Cochran, of Birkenhead, and all the most recent improvements for cargo purposes. The cabins are most tastefully constructed in teak, oak, and mahogany, in the poop aft.

A new screw steamer, the "Quito," built to the order of the Pacific Steam Navigation Company for their West Coast trade, was launched from the yard of Messrs. Laird Brothers, Birkenhead, on Saturday, the 28th ult. Her principal dimensions are: Length over all, 225ft.; beam, 35ft.; depth to upper deck, 22ft. 6in.; builders' measurement, 1270 tons. She is built of steel, with steel lower deck, and is designed to carry a large cargo, with space on deck for cattle and deck cargo. There will be accommodation on deck for sixty first class passengers. The saloon and state rooms are sumptuously fitted, and the former has a Mosaic floor of artistic design, which will be fully appreciated in the hot climate. The ship is fitted throughout with the electric light, and is provided with steam steering gear, and all modern appliances. The engines will be triple expansion, indicating 800 h.p.

On the 28th ult., there was launched from the shipbuilding yard of Messrs. Short Brothers, Pallion, a steel screw steamer, built to the order of Mr. J. S. Barwick, Sunderland. The following are the chief dimensions: Length over all, 325ft.; breadth, 39ft.; depth, 22ft.; and dead weight capacity, 4000 tons. The engines and boilers have been constructed by Mr. George Clark, of the Southwick Engine Works.

On the 30th ult., the steel screw steamer "Rapel," built for the Compania Sud Americana de Vapores, of Valparaiso, was launched from the yard of the Blyth Shipbuilding Company, Limited, Sunderland. The vessel has been specially designed for the South American trade, and will be equipped with four powerful steam cranes, &c., by Messrs. Robert Roger & Company, of Stockton-on-Tees. The engines and boilers have been constructed by the North-Eastern Marine Engineering Company, Limited, Wallsend-on-Tyne, and the donkey boiler by the Tyne Boiler Works Company, Walker-on-Tyne.

IMPROVED JAW CHUCK.

THE type of chuck which we herewith illustrate is an American design now being introduced into this country by Messrs. Clark & Wellington, of 73, Queen Victoria-street, London. Each jaw consists of two pieces, the lower, as usual, in one with the nut C (Fig. 2), which works over a screw for shifting the jaw, and the upper piece, which may be set farther in or out or reversed according to the size and shape of the job. The body of the chuck consists of a front and back shell arranged to screw on to the face plate of the lathe, and containing the gear for the universal or independent movement of the jaws as may be desired. The construction of this gear will be understood from Figs. 2 and 3, which show sections through a three-jawed chuck, whilst Fig. 1 is an outside view of a four-jawed chuck with independent jaws. The bevel pinions B can be brought simultaneously into gear with

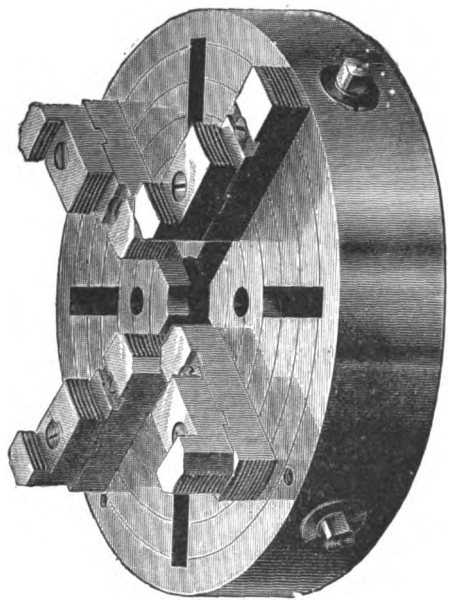

FIG. 1.

the toothed ring D, when the latter is lifted and backed up against the pinions by the ring H. In this position the turning of one pinion causes the ring D to revolve, and so to transmit an equal rotary motion to the other two pinions. At the bottom of the shell and opposite each pinion are projections G, and similar projections with tapering ends are fitted to the ring H, so that when the latter is turned by the thumb screw in one direction the projections are brought over each other, causing the toothed ring to come into gear with the pinions; whilst if the thumb screw is pushed in the other direction the smooth part of the ring H is brought over the projections G, and the toothed ring comes out of gear. The ring H is locked in either position by the thumb nut shown, and a plate covers the slot in the shell through which the thumb screw passes, so as to prevent turnings or filings getting into the gear.

IMPROVED JAW CHUCK.

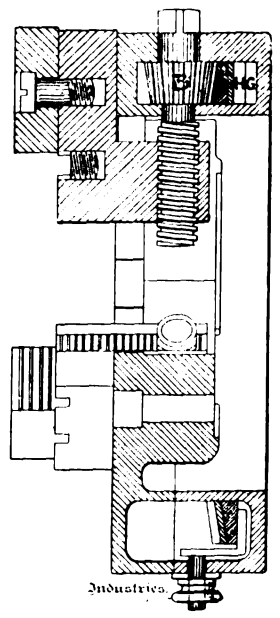

FIG. 3.

CENTRAL STATION LIGHTING.

(TRANSFORMERS V. ACCUMULATORS.)

IN our last issue (see page 432) we reported the second night's discussion on this paper, by Mr. R. E. Crompton, read at the Society of Telegraph Engineers and Electricians. The discussion was resumed on the 26th ult., and concluded.

The first speaker was Mr. W. B. Esson, who considered that the numerical results of the author's own experience were of great value, and regretted that he had not confined himself to these, excluding merely hypothetical calculations. It was generally agreed that accumulators charged with a current at 2·5 volts would give a discharge current of 2 volts, giving a maximum possible efficiency of 80 per cent. In actual practice probably even 70 per cent. would very seldom be attained, and the results obtained at Vienna, viz., an efficiency of 60 or 61 per cent., might be considered the general average. Mr. Crompton's estimate of £8,000 for the generating station, on the B.T. system, was too small; but he agreed with the author that his estimate for the cost of the alternating machines was below the mark, as at present their cost is much higher than that of continuous current dynamos. With regard to working expenses, he did not think there would be much difference between the two systems. He thought the reliability of either system would be about the same, for though there is an objection *per se* of moving machinery, there would be very little danger to a breakdown if a spare set of machinery were kept ready for use. On the A.T. system the alternative methods of distribution were: Large transformers feeding a network at 100 volts; or small transformers in every house, with a primary current at 2000 volts in a distributing network. He considered that our present experience would tend to induce distrust of the permanent reliability of an underground network carrying a current at 2000 volts. If the former system were used, the cost of the mains would be about the same as if accumulators were employed, except that the charging main in the transformer system would carry a current at 2000 volts, as opposed to one at 500 volts in the accumulator system, giving a considerable economy in favour of the transformers. He considered that, except in the matter of the charging mains, there would be very little difference in cost between the two systems.

Professor Forbes observed that the paper was of a character not often read before the Society, dealing, as it did, mainly with hypothetical results. He considered that the discussion was of much greater value than the paper itself. He would have liked a paper from Mr. Crompton describing the actual results obtained in Vienna and at Kensington Court, and giving precise details as to the efficiency of the accumulators. It was all very well for Mr. Crompton to say that anyone could go and inspect the Howell accumulators at the Kensington Court central station; but he, at any rate, was unaware of any method of testing the efficiency of an accumulator by merely looking at it when in use. The object of the paper, as set out by the author, was to show that distribution by means of transformers had no advantages over other methods. He had then selected an example as disadvantageous as possible to the former, viz., a small 10,000-light central station supplying a closely contiguous district. Therefore, even if he made out his case in the example selected, it would not prove his assertion. He might have considered numerous other systems, and there was no doubt that the least costly would have been the system recently carried out by Mr. Stanley in America, and referred to in Mr. Mackenzie's recent paper on transformers. The speaker had formerly obtained details of the cost of electrically lighting the club district of Pall Mall and St. James' from the secretaries of the clubs, and his calculations, based on these figures, and carried out with the assistance of Mr. W. H. Snell, showed that the cost per candle power per annum of the different systems was as follows:—

System.	Cost per candle power per annum. s. d.
Simple parallel system	2 0
Three-wire system	1 10½
Multiple series system	1 10
Multiple series system carried out in compliance with Board of Trade regulations as regards pressure at the house terminals	2 0
Simple series (Bernstein's) system	1 10¾
Transformers	1 11½
Storage batteries	2 4

The most important of Mr. Crompton's tables were those relating to the cost of installations and maintenance. He compared Table III. (see Vol. IV., page 406)—giving the cost of a plant for an output of 600 kilo.-watts—with the results obtained in America. With the Westinghouse transformer system in use there, 600 watts were obtained in the lamps per i.h.p. Mr. Crompton demanded 1450 h.p. instead of 1000, which would be sufficient according to American practice—that is to say, he added nearly 50 per cent. to the maximum, a reserve enormously exceeding what was requisite. This would reduce all the details of his estimate. The cost of dynamos and exciters per kilo.-watt given in the paper was correct according to the American estimate, but this would also include the cost of all adjuncts.

The cost of transformers Mr. Crompton estimates at £7,500, while it should have been £4,000. His chief error, however, was with respect to the mains, and arose from his not appreciating the advantages of the transformer system. His allowance of 22,000 yards of mains for 10,000 lights was too high. In a case like this no one would think of taking up the pavement and laying down culverts, because overhead wires were more suitable for a small installation of this kind. The pressure of 480 volts assumed by the author exceeded that allowed by law. His wires would carry a current of about 1500 ampères at this pressure, and for this he assumed that a wire of 2·55in. sectional area would be required, which could not be carried overhead. Still more would this be the case if the Board of Trade regulations were complied with. He would, therefore, reduce the estimate for the mains from £20,430 to £6,000, and the total cost of the station on the A.T. system should be £34,140, instead of £57,440, and it was the former figure which should be compared with Mr. Crompton's own estimate of £59,762 for the cost on the B.T. system. Mr. Crompton's calculations for the accumulator system also contained serious errors with regard to the efficiency. This he assumed to be 80 per cent. for the whole system—that is, for the conductors and accumulators combined—and he admitted a loss of 10 per cent. in the charging and 4 per cent. in the discharging mains. Professor Forbes found that the loss on the charging mains would be 12 per cent., making a total loss in the mains of 16 per cent., and therefore leaving only 4 per cent. for the loss in the accumulators, which would, therefore, have to give an efficiency of 96 per cent. Again, he gave 416 ampères as the rate of discharge of each cell for five hours, or 2080 ampère hours, and stated that they were capable of a rapid discharge of 1352 ampères. With this rate of discharge he only allowed 15 per cent. for depreciation. Professor Forbes did not know of any company that would agree to maintain storage batteries at this price. Mr. Preece, whose cells were being carefully attended to, had stated that they lost 1lb. in 16lb. during the first year. Mr. Crompton then assumed that he could get such cells as these at £40 each. This estimate of price he had only based on hearsay, as was also the case with his figures for the alternating system, which were to a great extent based on articles in *Industries*. If he had confined himself to his own experience, the results would probably have been very different. Mr. Crompton had stated that American experience was of no assistance; but the speaker, on the contrary, found that during the few months in which he had recently been studying the A.T. system in America, he had obtained more practical information than he could have gathered by reading everything that had ever been written by English authors on the subject.

Digitized by Google

Mr. Crompton had characterised as nonsense the statement that the cost of laying down conductors was approximately proportional to the cost of the copper. This would not be the case for small sections, but for these overhead conductors should be employed. For large installations requiring heavy mains it was necessary to put them underground, and for such installations—say of 100,000 lights—the cost of mains would be very nearly proportional to that of the copper. Mr. Crompton had offered to carry out an accumulator installation at his own estimate, it was true; but then he would not be allowed by the Board of Trade regulations to carry it out. On the other hand, the transformer system was allowed, and the speaker knew plenty of contractors who would be very pleased to carry it out on the alternating system at Mr. Crompton's estimate of £57,000.

Professor Forbes, at the request of Mr. Preece, next gave a short account of his experience of the transformer system in America, and stated that he had been specially impressed by the small number of men attending on the stations. As an example, he stated that at Denver, where coal was the fuel used, the staff for a 7000-light installation consisted of one manager at $150 a month, one secretary at $80, one office boy, two dynamo attendants at $70, two engine attendants, five firemen, two line inspectors, and one man for repairs. At Pittsburgh and Alleghany natural gas was used instead of coal, and the supply was regulated automatically, so that the boilers for a 10,000-light station were looked after by one man only. The Westinghouse engines were in very general use for alternate current lighting. They were not the most economical, but were very suitable; and the Westinghouse governor, which ran in an oil bath, was extremely sensitive. The dynamos differed greatly from the types used in this country. The field magnets consisted of an iron ring, with sixteen poles turned inwards. The armature was formed of thin iron plates bolted together, and wound with sixteen coils separated by wooden laths. The construction of these machines was excellent, both mechanically and electrically, and the heating was much less than would be expected. The power used in exciting was 2 per cent. of the total output. The weight of a 2000-light machine was 18,000lb., and the speed 1000 revolutions. The space taken up by the laths ought really to be occupied by useful material. If iron were put in the cost would be very largely increased, owing to the mechanical difficulties. He had suggested that the laths should be removed and replaced by a separate circuit lagging behind a quarter of a period. This would increase the output by 25 or 30 per cent. He had tested the converters at the Westinghouse Works at Pittsburgh by the same calorimetric method which Professors Ayrton and Perry had recently employed. He found that the 30-light converter, when working at half its maximum load, gave an efficiency of 95 per cent. Only three types of dynamos and five types of converters were constructed at the Westinghouse works; this restriction to a limited number of types enabled the machines to be manufactured on a large scale, and supplied at a much lower cost than would be possible if each machine were constructed to a separate specification, as was the custom in this country. It also had the advantage that if any part of a machine gave way, it could be supplied immediately from the works in answer to a telegraphic order. The switch boards in use at the American central stations were remarkably small and simple in comparison with those in use here for non-transformer systems. Some of the switches and other fittings used by the Westinghouse Company were exhibited.

Mr. J. E. H. Gordon pointed out with reference to the load diagrams exhibited, that while the London diagram showed a maximum demand at 7 p.m., that for Brooklyn was at 5-30, that for Cincinnati at 5-45, and that this exactly corresponded with the difference in the dinner hour in London and in the United States. Mr. Crompton had been put at a disadvantage by his desire to abstain from advertising his own wares. He himself had concluded a contract with Mr. Crompton for the supply and maintenance of Howell accumulators for the installation which he was carrying out at Whitehall. There were to be eight batteries of sixty cells each, and ten spare cells, at a cost of £6. 15s. per cell. The nominal rate of discharge was to be 105 ampères, with a capacity of 525 ampère-hours. At a discharge rate of 200 ampères the capacity was to be 375 ampère-hours. At 105 ampères discharge rate a minimum efficiency of 75 per cent. was guaranteed, 85 per cent. at 75 ampères, and 90 per cent. at 45 ampères. If these conditions were not attained, Mr. Crompton undertook to supply extra batteries at his own cost to bring the capacity and efficiency up to the required standard, by reducing the rate of discharge of each cell. The batteries were to be kept in a condition equal to new at a yearly rate of 12½ per cent. on the original cost.

Mr. Sellon thought that overhead mains will not be allowed in England as they are in the United States.

ELECTROLYTIC BLEACHING.

Strength of solution after electrolysis, 3·5 grammes chlorine per litre. Density of current 0·023 A. per square centimetre.

Most of the advocates of the transformer system admitted that distribution by accumulators was the ideal system, and that the other was only a stopgap. Accumulators had been discredited because they can go wrong without its being immediately evident, as in the case of dynamos. This objection would not apply to the system of distribution from local stations, where the accumulators would be under competent care. He considered that the ideal method would be the combination of continuous current transformers and accumulators. During the period of maximum demand the supply would be obtained from both sources; during the period of medium demand, or about half the time, the whole plant would be at work, and the surplus current would be used to charge the accumulators; during the period of minimum demand the supply would be from the accumulators alone.

Mr. B. Drake thought the public preferred the accumulator system, even if they had to pay more for the light. He advocated the same mode of working as the author, viz., running the dynamo continuously through the battery, and using the latter as a source of additional supply during the period of maximum demand, and also to guard against a breakdown of the machinery. The lighting during the day to be from the batteries only.

Mr. F. King thought Mr. Crompton might have used a higher pressure for charging. At Colchester they had used 1250 volts for two and a half years without a breakdown, and when the cables were taken up they were as perfect as when laid down, the good condition being due to their having been cased in lead. The speaker proposed to use a current of 2750 volts for charging. Mr. Crompton proposed only four subsidiary stations, and therefore the pressure would vary considerably; to avoid this, ten subsidiary stations would be necessary. He advocated the use of a complete storage system, as he did not think reliance could be placed on the continuous running of any dynamo, and he thought that accumulators could be constructed which could not be run down by any internal action. If the peroxide plate only lasted for three years, the accumulators could be maintained at a rate of 10 per cent. Storage batteries should never be charged in parallel, as very small differences in the counter electromotive force would produce large differences in the charging. He had made batteries which gave an output at the rate of 150 watts for seven hours, with a fall of only 4 per cent. in the pressure.

Mr. Stewart Russell thought that most of the failures in underground electric lighting cables, especially a few years back, arose from the use of inferior cables with light insulation, and with no mechanical protection. He gave instances of American cables laid underground for arc lighting from Thomson-Houston machines, which subjected them to a much greater strain than the A.T. system. Among other instances of successful underground cables he mentioned cables at Milan carrying a continuous current at 1500 volts, or an alternating current at 2000 volts; and a cable at Brussels, five miles long, carrying a continuous current at 1400 volts. At Silvertown, cables for arc lighting had now been underground for five years without requiring any repairs, and the two cables supplying fourteen or fifteen lamps had been laid side by side in the same trench.

Mr. Fleetwood observed that it would be quite impossible to put culverts such as Mr. Crompton described under most of the London streets, as the space was already so fully occupied that it was often impossible even to find room for 3in. pipes. He considered the use of iron pipes to be the best means of protecting permanent underground cables.

Production of Silver in Germany.—A report just issued on the present situation of the mining and blast furnace industries of the Cologne district, directs attention to the increase of the silver production of Germany since the year 1880. In that year the production amounted to 406,267lb., from which quantity it has gradually increased to 717,845lb. in 1887. The increase has chiefly taken place in the Cologne district.

ELECTROLYTIC BLEACHING.

At a recent meeting of the Society of Chemical Industry, a paper by Messrs. C. F. Cross and E. J. Bevan was read, upon the Hermite electrolytic bleaching process. The authors said that at the Liverpool section of the Society Dr. Hurter had severely criticised their first memoir on the subject, and spoken of it as unworthy of serious notice, because the results claimed to have been obtained were contrary to known chemical laws, for "if bleaching were oxidation" such results were impossible. They, however, responded that bleaching is not oxidation in the limited sense meant by him, and is not comparable with the conversion of FeO into Fe_2O_3. Certain conditions may modify the bleaching of cellulose: for instance, a solution prepared by passing chlorine into milk of lime has a totally different bleaching effect from a solution of bleaching powder of identically the same strength. In the experiments they had recently made, electricity was passed through a copper plate voltameter containing slightly acidulated copper sulphate, and then through a cell containing a 2½ per cent. solution of magnesium chloride. The plates were of such a size that the copper deposited was bright and coherent, and the voltameter was proved to accurately measure the electricity passing. The gases obtained from the chloride were collected in the nitrometer and analysed, and the total amount of oxidising chlorine determined with the results given in the above table, obtained from a typical experiment comparable with many others. The electrolysis was conducted in four stages, the gases were analysed each time, but the solution was analysed only at the end of the fourth period.

Platinum electrodes were used in the decomposition cell. They thought it might be worth while to thus compare Dr. Hurter's results with their own, and analysis of the solution proved that no perchlorate was present:—

Strength of Solution grms. Chlorine per litre.	Current Efficiency. Available.	Total.	Percentage of Total Chlorine available.
Dr. Hurter..... 3·19	... 21·8	... 47·5	... 45·9
Cross & Bevan 3·50	... 72·8	... 89·4	... 81·4

By using a stronger solution of chloride of magnesium greater current efficiency is obtained; but, for certain economical reasons having reference to the amount of $MgCl_2$ that would have to be wasted, a weaker solution than 14 per cent. of the crystallised salt is preferred, notwithstanding the lesser yield. In view of Dr. Hurter's assertion that potassium chlorate is converted into potassium perchlorate by electrolysis, they had tried it experimentally, and obtained no perchlorate at all. They found that the obtaining of it is simply a question of current density, governed by the size of the electrodes relatively to the current passing. An exhaustive series of trials had been made at Belfast as to the relative efficiency of the Hermite and the bleaching powder process, resulting as 4s. 8d. for the Hermite process, against 14s. 4d. for bleaching powder; the time by the Hermite process was 15min., as against 47min. when bleaching powder was used. They had made a careless mistake in their previous paper in saying that hydrogen peroxide was present. Dr. Hurter had not stirred his solution as the Hermite process demanded, and that had made a large difference in the bleaching efficiency indicated by his results. In conclusion, Mr. Cross mentioned that the process had been started in an American paper mill in January, and those using it now said that all the promises made about it had been fulfilled. In this statement the author was corroborated by Mr. Christie, who said that a friend of his, who was working the process on a large scale in America, was entirely satisfied.

Professor Dewar had no doubt that it was one of those cases explicable by the difficulties of electrolytic methods, although contrary to Dr. Hurter's knowledge and antecedent views. Messrs. Cross and Bevan had now established their position, in his opinion.

M. Hermite said that the process would bleach some valuable classes of fibre which other methods destroyed,

Digitized by Google

and that one firm of paper makers was bleaching 4½ tons of pulp per day with an excessively weak solution of chloride of magnesium; the results could not be accounted for on a theory of the bleaching efficiency of hypochlorite of magnesium. The bleaching compound is used in its nascent state, and an old solution does not work so efficiently. Dr. Hurter must have been using solutions at nearly the boiling temperature.

THE MANUFACTURE OF CHLORINE.

At the last meeting of the Society of Chemical Industry, Mr. C. T. Kingzett read a paper on the manufacture of chlorine, in which he described experiments made by him to ascertain if the Leblanc soda makers could utilise their spare hydrochloric acid by means of a permanent quantity of magnesia to be alternately converted into chloride by hydrochloric acid, and decomposition of the product by air at a high temperature, indefinitely, or by means of a nominal amount of magnesia to effect the interaction of air and hydrochloric acid vapour. In his first experiment he slowly passed dry air and dry hydrochloric acid gas for one hour through a red hot combustion tube containing a small quantity of magnesia and much asbestos, and obtained a certain amount of chlorine. Next he passed dry hydrochloric acid gas and common air through a combustion tube at a bright red heat, containing asbestos only, and obtained a smaller proportion of chlorine than before. In another experiment, he passed dry air for five hours over dry chloride of magnesium at a bright red heat, and obtained chlorine. In his fourth experiment, air was sent through fuming commercial hydrochloric acid, and afterwards for six hours over red hot pumice stone impregnated with a small quantity of magnesia, chlorine being obtained; and $MgCl_2$ being then present in the tube containing the pumice stone. He thought, therefore, that not alone chlorine but bleaching powder was economically made by the process. He mentioned that Henry Larkin and William White had, in 1870, received provisional protection for obtaining chlorine by the reaction of oxygen upon certain metallic chlorides at a high temperature. Mr. Ludwig Mond said that the paper did not go sufficiently into detail as to temperatures, and the proportions of oxygen and hydrochloric acid, consequently the value of the suggestions in it could not be estimated; the method had all the disadvantages of Deacon's process, whatever advantages it might have. Professor Dewar, president of the Society, did not doubt the results obtained in the few laboratory experiments described; but they could not be brought forward as novelties in advance of the Weldon-Pechiney process, which is now proving very useful in the manufacture of chlorates. That process depended largely upon good chemical engineering, and Mr. Kingzett should work with quantities of a ton at a time.

Notes.

JAPANESE IMPORTS.

A Foreign Office report on the exports and imports of Japan in 1887 gives the total value of the foreign trade at £17,500,000, an increase of £3,000,000. About three-fourths of this increase is in the imports. Cotton yarn was imported to the value of over £1,500,000, an advance of over £400,000 on the previous year. Brown sugar was taken to the amount of £470,000, an advance of over £90,000; but there was a falling off in refined sugar. Over 28,000,000 yards of grey shirtings and other cotton fabrics were imported, as against 20,000,000 yards in 1886, the increase in value being about £60,000.

PROGRESS AT THE FORTH BRIDGE.

The advent of spring has given a very notable impetus to the erection of the Forth Bridge, and the work of the last few weeks has been marked by important progress all over the structure. On the Fife cantilever the south bottom members now project over the estuary a distance of 280ft., and the north members are almost equally advanced. Tie I. is completed on both the north and south ends, and the internal viaduct is carried over the trestle at the end of Bay I. into Bay II. The top members are within 30ft. of the end of Bay I., and the first struts are built almost to their permanent junctions with them, while the second struts now extend 40ft. beyond their junctions with the bottom members. The positions of the Queensferry pier and cantilevers are almost the same as those of Fife, while the central ones at Inchgarvie are now only about ten weeks behind the others. Comparison between the progress reports for March and April strikingly illustrate the influence of the weather on the erection of the bridge. In March, when the work was very seriously retarded by this cause, the weight of steel placed in permanent position was 650 tons, while during April, the first three weeks of which have been most favourable to the work, and only the last unfavourable, the weight of steel erected has been 1700 tons. If the mild weather had continued during the last week the monthly return would have exceeded 2000 tons. This rate of progress is highly satisfactory to the engineers and contractors.

THE AUSTRALIAN RABBIT PEST.

At a recent meeting of the Académie des Sciences, in Paris, a sealed packet, deposited by M. Boné on 12th January of this year, was opened, containing a description of a method for dealing with the rabbit pest in Australia. The author suggests that a poisonous or asphyxiating gas should be introduced into the burrows in those districts which are infested with this vermin. Carbonic oxide, vapour of carbon bisulphide, and carbonic acid gas are proposed as those which would be the most effectual and cheapest to apply. Details of the proposed method and the means to be employed for simultaneously using this process of destruction over a large area have not yet been disclosed, but the author is confident that it would be found more economical than that suggested by M. Pasteur, or the present methods of extermination adopted by the Australian Government.

TECHNICAL EDUCATION IN INDIA.

Mr. Alfred Chatterton, B.Sc., has been appointed professor of engineering to the college at Madras. The selection was entrusted to a committee, appointed by the Secretary of State for India, which consisted of Sir Alexander Taylor, principal of Cooper's Hill College, Professor Unwin, of the City and Guilds of London College, South Kensington, and Sir Philip Magnus, secretary and director of the City and Guilds of London. The committee recommended two gentlemen, and of these Mr. Chatterton was selected. Mr. Chatterton received his preliminary education at St. Mary's College, Peckham; he subsequently studied at Finsbury Technical College, where, amongst other distinctions, he gained the Cloth Workers' exhibition and numerous medals. Mr. Chatterton's practical knowledge has been obtained at the locomotive works of the London and South-Western Railway at Nine Elms, where he has also been engaged in teaching the apprentices' evening science classes.

SHIPBUILDING IN GERMANY.

It is interesting to note that the output from the Vulcan Ship Yard, at Stettin, for the current year promises to be very large. In addition to being actively employed with repairing work on several ships, the company have in course of construction two large twin screw steamers, 460ft. in length, for the Hamburg and Bremen Lloyd's; two large paddle steamers; and two twin screw passenger steamers of about 270ft. in length. Altogether, there are upwards of 5000 men employed in this establishment at present. At Kiel, the various departments in connection with the Germania Schiffswerft are pretty busy. The firm has a fair amount of work in hand, and prospects are anything but cloudy. The torpedo boats already launched are being vigorously pushed forward towards completion, and the work in connection with the cruiser recently booked is well advanced The cruiser "Prince Wilhelm," which is supplied with triple expansion engines of 8000 i.h.p., will be ready for her preliminary trials on the measured mile in a few days, when it is expected that the stipulated speed will be exceeded.

THE WAR OFFICE AND METROPOLITAN HORSE OWNERS.

The *Times* states that the War Office have issued a circular inviting owners of twenty horses and upwards within the metropolitan area to register such a number of horses as they would be prepared to sell to the Government on the occasion of a great national emergency. Ten shillings per horse registered will be paid annually as retaining fee. Only serviceable horses of from five to ten years of age, and from 15 hands to 16 hands 2in. high, will be registered. Officers appointed by the Secretary of State will inspect the class of horse owners propose to register, on their premises, at least once a year, after which the final agreement will be made as to prices with the proprietors. The Government are prepared to agree to pay in case of taking the animals a price which would represent: (*a*) What it would cost to replace them; (*b*) the estimated loss which might accrue pending their being replaced. As it is evident that the amount of (*a*) and (*b*) above would vary in proportion to the number of horses required by the Government, the prices to be agreed upon should, it is considered, be based on a sliding scale. The following particulars should be given by owners of horses: (1) The number of horses of the description defined they are prepared to hold at the disposal of the Government in the event of their being required under an emergency; (2) the price per horse they consider should be given by the Government in the event of their horses being impressed—(*a*) if a quarter of the registered number be taken; (*b*) if one-half be taken; (*c*) if three-quarters be taken; (*d*) if the whole be taken. Varying rates can be named where owners have more than one class in possession. Forms of application can be obtained from Major-General F. G. Ravenhill, Inspector-General, Remounts, 69, Spring Gardens, S.W.

JAPANESE RAILWAYS.

The first railway constructed in Japan, which connects Tokio and Yokohama, was opened in June, 1872, and is the only double line of railway in the country. There are now open 245 miles of Government lines, 254 miles are in progress, and 52 miles more are in contemplation. There is also a line of 56½ miles in the island of Yezo. The Japan Railway Company, on whose paid up capital the Government guarantees 8 per cent. interest, has 289 miles of line open, and contemplates a new railway from Sendai to Awomori, a distance of 240 miles. The construction of a number of private railways has also been sanctioned by the Government.

NEEDLES IN CHINA.

The Chinese Commissioner of Customs at Wênchow reports that foreign needles find no market there, but samples of the native article have been sent through the Foreign Office to the Needle Manufacturers' Association, Redditch. The price is 5 cents or say 2d. per hundred. It is the only kind, as to make and size, fit for silk embroidery. The importance of the market may be measured by the fact that every well-to-do woman embroiders her own shoes (of which each pair lasts at the most two months), and her own head gear, besides fans, screens, and the like. The smallest foreign needles hitherto imported at Wênchow have been No. 12 "betweens," at a price of 9 or 10 cents per hundred, wholesale, and these are considered to be only fit for tailor work.

PRICE OF WHEAT.

In view of the present low price of wheat, the opinion expressed by Mr. Edward Atkinson, the well known American economist, in a recent letter to the editor of *Bradstreet's*, deserves attention. Mr. Atkinson not only re-affirms his position that the American farmer can sell wheat at London at 34s. per quarter with as much profit as when wheat sold at 50s., but after re-examination of the subject, concludes that America can compete as favourably to-day with wheat at 28s. as fifteen years ago at 30s. This is not a very encouraging prospect for either the British farmer or landlord. In connection with this subject it may be interesting to note that the fall of prices of ocean transit from New York to Liverpool has been as follows:—

	1880.		1886.
Grain, per bushel	9½d.		1d.
Flour, per ton	25s.		7s. 6d.
Cheese	50s.		15s.
Cotton, per pound	⅝d.		5/16d.
Bacon and lard, per ton	45s.		7s. 6d.

BULL'S METAL.

We have this week seen samples and test pieces made from a new alloy containing copper, zinc, and some other metals, which at present are the secret of the inventor, Mr. John Bull, of 18, Adolphus Road, Finsbury Park. The metal is at present prepared in two varieties. One is a soft variety which is more adapted for cold working, and which has a tensile resistance of slightly over 30 tons; the other is a strong variety, with a tensile resistance of nearly 35 tons; but this alloy is not so well adapted for cold working. Both varieties can, however, be forged and stamped at a dull red heat, the same as wrought iron. In the diagrams which have been prepared from tests made by Messrs. J. Buckton & Co., of Leeds, and which we have had an opportunity of inspecting, the strong metal exhibits a very peculiar property. Shortly after the elastic limit has been passed, which happens with a load of 24 tons, there is a sudden drop in the curve; but on further straining the metal it seems to recover itself, and there is as sudden a rise, so that finally the curve passes on as if this period of unstable equilibrium had not existed. Certain qualities of mild steel exhibit a similar property; but we have never seen it so marked as in this metal. At the tests referred to, the hot rolled sample bar of the strong metal broke at 34·76 tons, with an elongation of 19·3 per cent.; whilst the soft metal showed 30·46 tons tensile resistance, with an elongation of 30 per cent. We have seen test pieces of Bull's metal made from a round bar at a dark red heat, which in finish leave nothing to be desired. The inventor states that the metal can be cast like gun metal, in dry moulds. The chief precautions to be observed are to use a large head, stir up and skim well, and pour quickly.

Patent Record.

Compiled from "The Official Journal of the Patent Office," by W. E. Heys, *70, Market-street, Manchester.*

APPLICATIONS FOR PATENTS.

(The names in italics within parentheses are those of Communicators of Inventions.)

ENGINEERING.

20th April, 1888.

5872. Theermann, W. P. ..... Gas engines.
5880. Kelso & Hill ..... Indicating and recording speed of engines.
5882. Stanley & Vicarman... Automatic letting off and taking up motion for looms.
5883. Merrall, E. R..... Machinery for twisting or doubling yarns or threads.
5887. Poyser, J..... Sewing machines.
5890. Hawkins, F. P..... Steam engines.
5892. Müller, F. W..... Sewing machines.
5896. Mouradian, M..... Apparatus for drawing a thread from woven cloth for the purpose of testing it.
5911. Smith, M. H..... Railway rolling stock and arrangement of switches.
5914. Lake, H. H. ..... Hydrocarbon engines (*Spiel*).
5915. Pitt, W. A..... Steam engines.
5919. Cotton, J..... Steam boilers.
5927. Preston & Cornish ..... Apparatus for establishing communication with pipes containing fluid under pressure.

21st April, 1888.

5929. Eddington & Steevenson ..... Brick moulding machines.
5930. Merrall, E. R..... Faller operating mechanisms of gill boxes used in the preparation of wool.
5939. Elliott, G. W..... Grinding and pulping machines.
5940. Dack & Barlow ..... Transferring vessels from one canal to another.
5941. Hetherington, J. M.... Carding engines.
5942. Butterfield, F. ..... Wheel and rack cutting and dividing machines.
5945. Hill & Hill..... Cold iron sawing machine.
5948. Scott, W. ..... Rolling machines for stripping cloth off cropping machines.
5954. Crawford, M. ..... Machines for removing the lint from cotton seed.
5956. Newman, T. W. ..... Machinery for drying at a high temperature.
5957. Cook & Buchanan ..... Manufacture of paper boxes.
5958. Parker, H. ..... Manufacture of paper.
5960. Stubbs & Heaton ..... Reeling yarns.
5961. Skinner, G. J. C. d'U... Slide valves.
5963. Schoder, E. ..... Production of metal paper.
5965. Delhaye, H..... Apparatus for elevating grain.
5966. Barraclough, T. C. ... Machinery for dressing ramie (*De Landtsheer*).
5972. Rayner, T. J. ..... Steam generation for distilling purposes.
5973. Simpson, W. S..... Fire arms and ordnance.
5980. Gibbs, W. A..... For the production of hot air for drying.
5982. Fricker, G. C..... Cleaning the surfaces of metallic bodies.

23rd April, 1888.

5989. Buxton, J. H., & others Newspaper printing machinery.
5997. Turner, C. ..... Loose reed looms.
5998. McCallum & MacCllum Hand printing presses.
5999. Kirk & Lee ..... Apparatus for finishing woven fabrics.
6028. Malvez, M. ..... Polishing and grinding plateglass.
6031. O'Neill & O'Neill..... Compressed air engines.
6032. Hallatt, B. ..... Twist lace machines.
6034. Mayos, T. T..... Apparatus for compressing hay.
6036. Gaze, E. H. ..... Gas engines.
6040. Poyser, J. ..... Sewing machines.

24th April, 1888.

6054. Emmens, S. H. ..... Ordnance and small arms.
6058. Robinson, C. H. ..... Tube expanders.
6060. Marjerison, J..... Spinning or twisting machinery.
6061. Dewees, J. W. ..... Sewing machines.
6065. Taylor, E. ..... Steam engines.
6066. Farrer, J. W., & others. Signal apparatus for tramways.
6069. Vickerman, J. ..... Sizing, warping, and beaming machines.
6071. Serjent, G. E..... Bearings for machinery.
6074. Whitwam, H. ..... Looms.
6078. Pullan & Spence ..... Type writing machines.
6080. Larsen J. D. ..... Tramways and railways.
6081. Burdon, L. L. ..... Manufacture of compound ingots
6083. Burdon, L. L. ..... Straightening metallic tubes.
6084. Whitney, A..... Machine for milling twist drills.
6088. Thompson, W. P..... Gas engines (*Durand*).
6094. Bryce-Douglas, A. D... Marine boilers.
6095. Russell, J. ..... Portable ramps for railways.
6096. Brisay, J. D..... Valve gear.
6097. Lake, H. H. ..... Apparatus for facilitating the repair of ships' propellers (*Kirkham*).
6098. Fletcher, G. ..... Sugar cane mills.
6101. Lindheimer, F. O. ..... Crushing and grinding mills.
6106. Austin, H. K. ..... Axle boxes and bearings.
6108. Wells & Pickburn..... Hot air motors.
6109. Wells, C. ..... Obtaining power from the heat contained in waste steam.

25th April, 1888.

6118. Bellhouse, E. L..... Hydraulic packing apparatus.
6124. Smith, W. ..... Machines for agitating substances.
6128. Thompson, W. P..... Fluid pressure motors (*Lemonon*).
6147. Hodgkinson, J., and others ..... Mules.
6153. Armstrong, J..... Apparatus for blowing & moulding glass.
6154. Schenkenwald and Osborn..... Manufacture of paper.
6156. Jagger & Priestman... Manufacture of cloth.
6159. Vismes, Count A. V. de Drilling machine.
6163. Daniels, F. H..... Reeling apparatus for rolling mills.

26th April, 1888.

6165. Jardine, J. ..... Carriages employed in lace machines (*Sival*).
6166. Gaunt & Stansfield ... Looms.
6168. Simpson, H. C. ..... Water wheels and paddle wheels.
6179. Linkleter & Linkleter Deck seats self convertible into lifeboats.
6181. Hollingworth, E..... Shedding and taking up motions of looms (*Hutchins*).
6187. Hacking, W. H..... Drop box looms.
6201. Comings, W. R..... Machinery for cutting blanks (*Knowlton*).
6203. Margetson & Hek..... Waggons and vans.
6208. Reynolds, C. L., and others ..... Sewing machines.
6209. Cowburn & Peck..... Looms.
6210. Hovell-Thurlow-Cumming-Bruce, T. J. ... Fire engines.
6211. Witthoffft, L. ..... Circular saws.
6219. Goodwin, A..... Hydraulic meter or motor.
6224. Ford, T. P. ..... Valve operating apparatus for hydraulic lifts.

ELECTRICITY.

20th April, 1888.

5870. Rauschke, R..... Electric batteries.
5898-99-900. Chadburn, W... Telegraph apparatus for communicating between one part of a navigable vessel and another.
5913. Heaviside, A. W..... Electric telegraph, telephone, and electric light insulators.
5922. Stuart, G..... Joining electric conductors.

21st April, 1888.

5937. Collingridge, A..... Galvanic salts.

23rd April, 1888.

6046. Fischer-Treuenfeld, R. von..... Coupling for electrical conductors

24th April, 1888.

6075. Ries, E. E. ..... Heating by means of electricity.
6076. Gross, A. ..... Electrical appliances for a mariner's compass to give alarm upon deviation from the ship's course.
6093. Jacob, F. ..... "Morse inker" apparatus for telegraphic purposes.
6100. Todman, J. T. ..... Locking electrical indicator.

25th April, 1888.

6133. Boardman & Teague ... Electric arc lamps.
6157. Keen, R. E. ..... Electric arc lamps.

26th April, 1888.

6184. Ruddle, M. ..... Telephones.
6191. Schroeder, C. A. J. H. Carbons for electric lighting.
6214. Farquhar, C. W..... Laying underground electric conductors.

CHEMISTRY.

20th April, 1888.

5909. Abel, C. D..... Blue colouring matters (*Actien Gesellschaft für Anilin Fabrikation of Berlin*).
5910. Abel, C. D..... Azo colouring matters (*Actien Gesellschaft für Anilin Fabrikation of Berlin*).

21st April, 1888.

5949. Kuhnt & Deissler..... Explosive compounds.
5953. Daudenart, L. G. G. ... Extracting magnesia from sea water.
5971. Haddan, H. J. ..... Extraction of oil by the naphtha process (*Evans*).
5981. Saunders, T. S. ..... Soap.
5985. Lewkowitsch, J..... Obtaining fatty acids and glycerine from fats and oils.

23rd April, 1888.

6026. Hucks, W..... Treatment of brewers' worts.

24th April, 1888.

6102. Jensen, P..... Extracting metals from ores (*Russell*).
6104. Weirich, J. ..... Treating auriferous ores.

25th April, 1888.

6151. Chatfield, R. E..... Ammonia carbonate.
6152. Chatfield, R. E..... Manufacture of ammonia and its sesquicarbonate.

26th April, 1888.

6175. Parnell & Simpson ... Production of sulphur from sulphuretted hydrogen.

MISCELLANEOUS.

20th April, 1888.

5865. Gye, P..... Landing nets for fishing.
5866. Payne, S. J..... Powder for cleaning and polishing plate.
5875. Cochrane, J. G..... Sectional revolving brush.
5876. Hugel, J. ..... Tools for preparing dowel and tenon sockets.
5877. Oates, W. ..... Apparatus for forming gullies and traps.
5881. McAra, A..... Cement.
5886. Morawetz, G. V..... Lamp chimneys.
5889. Travers, W..... Pedals for velocipedes.
5893. Paris, R. J. ..... Composition for protecting ships' bottoms.
5902. Fairfax, J. S. ..... Velocipedes.
5903. Nicol, A. ..... Handles for writing instruments.
5905. Lawrie, T..... Protections for cellar openings.
5908. Hill & Mayfield..... Drying apparatus for developing aniline dyes.
5912. Smith, W..... Filling paraffin lamps.
5917. Spence & Spence..... Fire resisting materials.
5921. Kreysler & Mohr..... Ornamentation of glass and ceramic ware.
5923. Austin, H. K. ..... Lubricating axles.
5924. Burton, E..... Apparatus for screening.
5928. Winterros, C. E..... Driving belts.

21st April, 1888.

5934. Roberts & Elliott ..... Coke forks.
5935. Benson, W. A. S., and others..... Artificial lighting.
5944. Whitehead & Ball ..... Holders for gas burners.
5946. Skinner, C. E. ..... Velocipede pedals.
5950. Rawlings & Rawlings. Blow pipe apparatus.
5951. Wigzell & Pollit ..... Trip gear for valves.
5962. Charles & Wells ..... Safety lamps.
5969. Barfoot, H. ..... Chimney pots.
5970. Burrow, W. B., & others Apparatus for bottling liquids.
5976. Utter, H..... Barbed fencing.
5977. Vavasour, Sir W. ..... Valves.
5984. Player, J. E. ..... Railway lamps.

23rd April, 1888.

5990. Sainty, J. ..... Fencing.
5993. Hoop, J. F. H. van der. A secret lock.
5994. Lindon, H. ..... Hoop fastenings.
6005. Tanner & Howe..... Taps and cocks.
6007. Coulson & Mulholland Lubricating journals.
6010. Sutcliffe, R. ..... Hinge.
6012. Wailes & Dove ..... Preservation of metal structures from corrosion.
6015. Fehlen, A..... Apparatus for warming rooms.
6016. Lee, W. ..... Manufacture of ears for buckets.
6019. Thornelor, J..... Fire lighters.
6020. Grandjean, E. F. L. ... Watches.
6022. Bickle, J. ..... Metallic packings for pistons.
6029. Gross, H. ..... Dyeing cotton.
6030. Harvey, R. ..... Eliminators for saccharine liquids (*Cornish*).
6035. Woodward & Foster... Utilising scrap leather.
6039. Dando, I. T. ..... Ventilators.
6044. Johnson, J. Y..... Oil lamps (*Upton*).
6045. Gooch, W. D., & others. Lamps.
6047. Imray, O. ..... Heating liquids (*Aries*).
6050. Davies, A..... Automatic ball and nut lock.

24th April, 1888.

6051. Welsh, S. ..... Destroying sewer gas.
6053. Schumann, C. B. ..... Extension ladder and hose carriage.
6062. Buckley, W..... Metallic packings.
6070. Schott, G. A. J. ..... Purifying sewage (*Lortzing*).
6072. Neilson, A., & others... Gas lamps.
6073. Turner, W. ..... Joining driving straps.
6077. Wallwork, R..... Instrument for screwing and unscrewing pipes.
6087. Wild, A. J. T. ..... Manufacture of bottles.
6089. Butzke, F..... Regenerative gas lamps.
6090. Shaw, H. ..... Cisterns.
6092. Thompson, G. H..... Fire escapes.
6099. Paling, F..... Securing corks in bottles for containing aerated liquids.
6103. Brothers, C. ..... Ventilator.
6105. Chinnock, A. S., & ors. Preparing china clay.
6107. McEvoy, C. A. ..... Ammunition.

25th April, 1888.

6112. Taylor, G. B. ..... Key stopper bottle.
6114. Kemp, J. R., & others... Shuttle boxes.
6115. Tye & Ancil..... Slides of gasaliers.
6121. Turner, T. H..... Wire grain screens.
6123. Helliwell, R. B. ..... Fire lighters.
6125. Boulay, D. de la M. du. Horseshoes.
6126. Kilner, T. ..... Forming glass bottle necks.
6127. Merryweather and Jakeman ..... Pipe connections.
6129. Hart, A. ..... Oil lamps.
6132. Minto & Smith ..... Ports for the discharge of water from ships' decks.
6134. James, S. H..... Sounding apparatus.
6135. Mitchell, W. ..... Ladders and fire escapes.
6136. Woolley, T..... Coating the bottom of iron ships.
6143. Davies, E. A. ..... Galvanised cisterns.
6144. Sharples, T., & others. Stoppering bottles.
6146. Delton, A. ..... Valves.
6148. Hughes, G. ..... Rapid engraving with immediate stereotyping (*Motteroz*).
6150. Heenan, R. H..... Stirring and mixing substances.
6160. Hall & Hall ..... Fire extincteurs.

26th April, 1888.

6169. Hoblyn, W. P..... Smoke consuming arrangement.
6171. Lawton, J. E. ..... Lubricator.
6172. Kirk, A. S. ..... Metallic fence.
6174. Hughes, T. ..... Sliding gas chandeliers.

Digitized by Google

6183. Burgess, J. T. M. ..... Taps.
6185. Rochester & Dejean... Horseshoes.
6186. Blakeney, W. H..... Pneumatic carrying apparatus.
6188. Fourness, W. A. ..... Regenerative gas lamps.
6189. Jones, W. ..... Gas light reflectors.
6193. Brooks, H. ..... Bottle stoppers.
6196. Royle, J. J ..... Connecting hose pipes to water fittings.
6197. Mayall, E. ..... Filling cartridges.
6199. Brown, R. ..... Securing covers of ships' hatches.
6202. Jenkins, T. ..... Revolving gas lights.
6205. Barkley, W. M. ..... Stop for gates.
6206. Palmer, C. A. E. T..... Velocipedes.
6207. Arnold, G. E. ..... Pipe joints.
6212. Tellier, C. ..... Producing cold by means of waste heat.
6213. Engert, A. C. ..... Reflectors.
6215. Lawton & Blackman... Packing cases.
6222. Palmer, W. ..... Eaves gutters.
6225. Pullin, A. R. ..... Signals.

COMPLETE SPECIFICATIONS ACCEPTED.

Persons interested in opposing the grant of the following patents may give notice of opposition at any time within two months after the dates given.

ENGINEERING.

28th April, 1888.

5957. Greth, J. ..... Colour printing.
6143. Beckwith, H. J. F. ..... Sight feed lubricators.

ABSTRACTS OF BRITISH PATENT SPECIFICATIONS.

Compiled from the Published Specifications by W. E. Heys, 70, *Market-street, Manchester.*

ENGINEERING.

Mitre Planing Machine.—*G. T. Webster, Drypool, Hull.*—The object of this invention is to construct a mitreing machine which shall be simple in its parts. One end of the iron case A is cut at an angle of 45°, and two slides J are bolted to it. The plane B works in these slides, and is centrally pivoted by

the pin K to the connecting rod C. The shafts F and H turn in suitable journals, which are supported by the frame work, and the band M passes round the wheels G and L. On the wheel L being turned by hand or by power, the band M, wheel G, pin D, and connecting rod C transmit the motion to the plane B. The wood is inserted in the case A, and is pressed against the end I; the incline of the mitre which is obtained is constant. Three claims are made for the inclined end, which is provided with guides, and for the employment of the plane to run in these guides, as described.—No. 793. January 18th, 1888. 6*d.*

Hardening Steel.—*R. A. Hadfield, Sheffield.*—The stee article to be tempered is made partially hollow, and a continuous stream of cold water is fed through its interior, when it is placed in position in the furnace. The running water keeps the interior of the steel cool, while the outer portion is heated to any degree, according to the temper required. After being heated, the steel is removed and immersed in the usual bath. Instead of water, the inventor sometimes charges the hollow portion with some metal which has a low melting point, such as lead, and by this means the temperature of the interior can be more perfectly regulated, and injury from expansion prevented. By these two processes, a gradually varying condition from hardness to softness is obtained in the steel. Two claims are made, one for each process.—No. 6173. April 27th, 1887. 6*d.*

Digitized by Google

MACHINE FOR DRYING FABRICS.—*G. Tolson, Dewsbury.*—A chamber is mounted upon central trunnions, upon which it is made to rotate or oscillate. The materials to be dried are placed inside the chamber, and a current of hot air is forced in through a tube in one of the trunnions. Valves and dampers are employed to regulate the supply of air. In another form of apparatus the chamber is made stationary, while the fabrics are agitated by a number of oscillating or rotating forks. Two claims are made, one for each form.—No. 6254. April 29th, 1887. 8*d.*

STEAM BOILERS.—*J. P. Bordone, Paris.*—The improved form of boiler described in this invention is illustrated in the two accompanying figures. Fig. 1 represents a longitudinal section of a locomotive boiler, and Fig. 2 a transverse section of a modified form. A is the steam collecting cylinder, and B the feed water heating cylinder; C is the mouth of the furnace, and D D^1 D^2 the furnace bars, counterweight, and lever of the

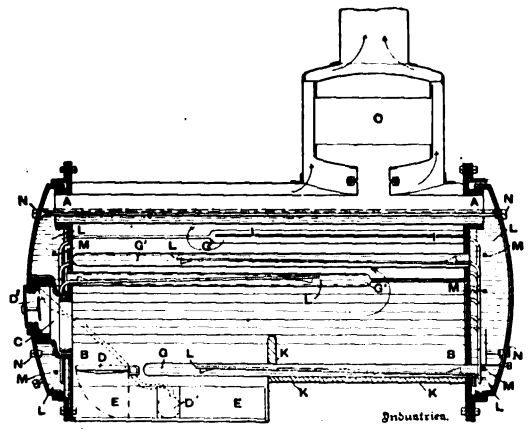

FIG. 1.

fire bars respectively. E is the door of the ash box, G are the grate tubes, G^1 the heating tubes, and I the obstructing bars. L are the small circulating tubes, and M the rods for maintaining the circulating tubes in place. N is a movable plate, and O O^1 are the domes for drying the steam. In Fig. 2 is shown the adjunct P to the chimney, forming a steam drying device. The series of tubes Q form a passage for the water and steam accumulated in the collector, and the tube R returns the water to the lower part of the boiler. The movable sheet metal plate S closes the upper flue round the cylinder which supports the engine T, while the flue serves as a steam dome. The water grate is shown at V, and X are nozzles forming intermediate

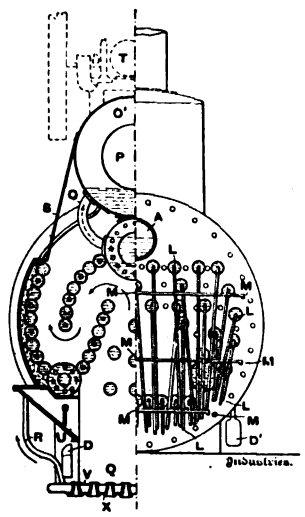

FIG. 2.

stays. The tube A serves as a steam collector, and carries the steam to the dome O. The steam is here superheated by the gases, which pass in the direction of the arrows. The pipes B are arranged symmetrically in the lower part, and serve as heaters for the feed water. The tubes are arranged as shown, and act as baffle plates to cause the most advantageous circulation of the products of combustion. Another advantage of this arrangement is that a rapid circulation is insured between the coldest and hottest parts of the boiler. The feed water is retained in a state of repose in the heating cylinders B, and the water in other parts of the boiler is efficiently circulated, so that all impurities of the water are deposited at once. Five claims are made for these arrangements of the tubes of the boiler.—No. 15326. November 9th, 1887. 8*d.*

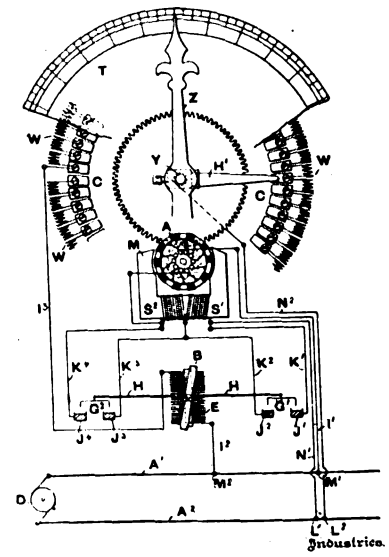
BOILER FURNACES.—*J. Lyle, Paisley.*—This invention relates to the application of petroleum as fuel in ordinary boiler furnaces. The ordinary furnace bars are removed, and the charging doors are securely closed; a new close plate is fixed over the entrance to the ash pit, and to it are secured the new fittings which are required by this invention. When compressed air is used for forcing in the oil spray, a small auxiliary engine is employed. The air pipes are led through stuffing glands in the lower central part of air supply boxes which are secured to the closing-in plate; the boxes are also provided near the centre with two cocks and knee branches, which lead into a spray jet burner on each side. A corresponding general oil supply pipe is led along and below the front of the furnaces, and is fitted with vertical branches and screw couplings leading up to the centre of each furnace; a knee and coupling is led through the lower spray furnace plate into a T branch in the inside of the plate and furnace, and the oil is heated during its passage through it. The T tubes are each to be led out at their extreme ends through coupling knee branches on the outside of the plate, and on the opposite side of the spray apparatus, to those of the air branches. These branches are here similarly coupled on the opposite side to the air branches, so that each spray apparatus can be swivelled up on these double sets of couplings, for cleaning their nozzles and orifices. Each spray apparatus consists of an internal central tube, with a conical jet nozzle in front, and with a lateral oil supply branch on the outside. The compressed air is supplied to the burner through an outer annular tube close to the hinder end, and is led forward to a conical nozzle in front of the internal tubular nozzle. Screws regulate the distance apart of the two nozzles. The apparatus is fitted with a short widening-out entrance part of a combustion chamber, projecting a little beyond the nozzles so as to rest on a large checked widening-out main combustion and air supply chamber, with small air inlet ducts, secured by a flange to the front plate of the boiler. By turning the flange, any desired amount of air may be made to enter the furnace. An angular platform of fire clay is supported on brackets, and extends across the whole furnace. The flame is by means of this platform deflected upwards, and caused to fill the whole flue. Five claims are made.—No. 6774. May 9th, 1887. 8*d.*

BRICK MAKING MACHINES.—*W. Barker, Birtley, and R. F. Boyd, Houghton-le-Spring, Durham.*—The inventors discontinue the use of the vertical rollers which served the purpose of collecting the clay, and substitute for them a pair of curved guides. Two of the sides of the die are parallel to each other, and the top and bottom only are tapered. By this arrangement the bad effects of the retardation of the clay against the sides of the die are, to a large extent, avoided, and the lateral and middle portions of the clay are delivered uniformly to the cutters. There are five claims.—No. 4458. March 25th, 1887. 8*d.*

STEAM ENGINES.—*J. Maynes & C. L. Watchurst, London.*—By these improvements the mean effort on the crank can be varied in exact proportion to the work to be done, without interfering with the ratio of expansion, the steam pressure, or the speed of the crank. The object is accomplished by increasing or decreasing the stroke while the length of the crank remains the same. In carrying out this idea the inventors interpose a curved link and sliding block between the piston rod and the connecting rod. Six claims are made for the mechanism employed by this method.—No. 4659. March 29th, 1887. 1*s.* 1*d.*

LOADING SHIPS.—*A. B. Brown, Edinburgh.*—A pair of horizontal girders can be moved in guides, so as to project from the side of the vessel just below an upper deck. A small truck runs on the pair of girders and carries two pulleys, between which hangs the loop of a chain and a tackle pulley for carrying the load. One end of the chain is fixed to the outer end of the girders, and the other end is led round pulleys which are worked by hydraulic power. The same means is employed for moving the girders and the truck. Three claims are made.—No. 6810. May 10th, 1887. 8*d.*

COTTON WASTE MACHINES.—*J. D. Tomlinson, Rochdale.*—This invention relates to the toothed coverings of the cylinders, doffers, and rollers of machines used for treating engine cleaning waste. Hitherto such coverings have consisted of iron or wooden lags, or of strips of leather, into which the teeth are inserted. When the teeth had been inserted, they were bent to the requisite angle. This arrangement necessitated the use of soft steel, and, as a consequence, the teeth were easily broken. According to the present invention, each tooth is made singly and bent to the proper angle; the teeth are then hardened before their insertion in the lag. The foot of the tooth is formed with a head, and is squared at the neck; the iron lag is bored to receive the teeth, and may be countersunk on the lower side to receive the head. The lags are bored of such a size that the teeth must be driven forcibly in. The inventor claims the provision of the rollers with steel teeth, which are formed with a head, and with a squared neck, and finished, bent, and tempered before insertion on the lags.—No. 8729. June 17th, 1887. 8*d.*



NAIL MAKING MACHINES.—*C. March & W. Dick, Glasgow.*—In the machines to which these improvements are applicable, the nails are cut transversely from strips of iron or steel, and the taper is imparted to them by presenting them at a slight angle to the cutters and whilst being turned half round between each cut. The strip is raised a little between each cut to allow of its being turned over, and in order to effect this motion the present inventors make use of a cam, a spring, and a fixed surface on which the cam bears. The cam is fixed on and encircles the holder, through which the strip is fed, and by means of which it is turned over. The cam is made with flat surfaces on opposite sides, and each flat surface extends equally on both sides of the point which is directly under the middle of the horizontal position of the strip. The fixed bearing surface is made of equal extent with the flat surface of the cam, so that there is no tendency to rock; and the holder is made to bring the cam quickly to its bearing after each turn over. Another part of this invention relates to the dies which form the head. When the blank is severed, it is held by a gripper which bears upwards on the under side of the nail, and holds it against a lip on the inner face of the stationary piece. When the heading operation is completed, the gripper travels backwards and removes the dies. The motions of the gripper are obtained by cams on the main shaft, and by springs and levers. Two claims are made, one for each improvement.—No. 7538. May 25th, 1887. 8*d.*

DANDY ROLLS FOR PAPER MAKING MACHINES.—*R. Brown, Penicuick, Midlothian.*—In constructing the dandy rolls which are used for making the water lines in paper, the inventor first covers a cylindrical frame with coarse wire cloth. A "laid" wire is then wound spirally over the woven cover, and soldered at each end, and on top of this wire are soldered a series of longitudinal line mark wires. The laid is thus made to run along the machine, instead of across it as heretofore; it is claimed that this arrangement produces a better "laid mark," and also permits of a higher speed. One claim is made.—No. 6563. May 4th, 1887. 8*d.*

ELECTRICITY.

DYNAMOS.—*R. E. B. Crompton & J. Swinburne, Chelmsford.*—The present practice of the makers of dynamos of the drum armature type is to wind the armature with little wire and with few ampère turns. The inventors reverse this method, and make the ampère turns comparatively large. For small machines, in which this method of winding is adopted, it is preferable to use single horseshoe magnets. The pole pieces are made to offer as little magnetic resistance as possible to the induction of the field magnets, but to oppose as great resistance as possible to the cross induction. The section of the iron connecting one horseshoe with another is made small; it is allowable to let the horseshoes be absolutely separated; but it is preferable to make the internal surface of the pole pieces practically continuous in order to avoid the heating of the armature bars. The armature is made up of thin discs of soft iron, and the spindle on which they are strung is made of manganese or other steel. In large armatures, the inventors employ the usual end connections, arranged in two layers, but of an improved form. The path of the conductor is first inwards towards the axle, and then away from the armature head in a direction parallel to the axis. Afterwards the path curves toward the other conductor in a plane at right angles to the axis. The connectors thus form two layers. The inner parts of the connectors are made radial, and the outer parts are curved as much as possible. The connectors are made so that they can be disjointed at their central part; the object of this construction is to allow the radial part to be withdrawn whilst the other part is not disturbed. At one end of the armature the commutator sections may form part of the connectors; but it is preferable to connect them separately, so as to admit of ventilation. The inventors make twelve claims.—No. 6754. May 9th, 1887. 11*d.*

ELECTRICAL MEASURING AND INDICATING APPARATUS.—*C. D. Abel, London.* (*Siemens & Halske, Berlin.*)—The apparatus here described is adapted to obtain reliable indications without requiring the attendance of experts. Two parallel circuits, the regulating and measuring circuits respectively, are employed, and are supplied from one source of electricity. Apparatus in the regulating circuit maintains the strength of the current in the second circuit constant. The application of this invention to the measurement of the difference of potential is illustrated in the accompanying figure. Two main conductors A^1 A^2, whose difference of potential is to be measured, lead from the current producer D to the outer circuit; from them branch the regulating circuit, in which are included the coils S^1 S^2 of the field magnets and the coils A of the armature of the motor M. The measuring circuit also branches from the main conductors, starting from the point M^2 and passing through the coils of a solenoid E, through the

resistance coils W of the measuring apparatus, and through a contact lever H^1. The solenoid E is surrounded by a pivoted frame B, with the axis of which is connected a two-armed lever H of insulating material; to each end of the lever are fastened the forks G^1 G^2 of conducting material. Under the prongs of these forks are two pairs of mercury cups J^1 J^2 J^3 J^4. The cups J^1 J^2 are in connection through the leads K^1 K^2 with the ends of the coil S^1, and the cups J^3 J^4 with the coil S^2, so that by the inclination of the rod H in one direction or the other, the coils S^1 or S^2 are short circuited. With the normal current tension at the terminals of the generator D, the frame B of the solenoid is so placed that the forked lever is horizontal and the coils of both limbs of the field magnets of the motor are in series in its circuit. As soon as the tension increases or decreases, the frame of the solenoid is turned, and the coil of one or other of the magnets of the motor is short circuited, and the rotation of the armature of the motor ensues. The axis of the armature is connected with the axis Y of the measuring apparatus. The pointer Z and lever H^1 are made to move, and the lever H^1 travels over the contact plates C and introduces more resistance into the circuit of the solenoid, until the proportion of total resistance between the points of connection of the measuring circuit with the main circuit to the current tension between these points again becomes a normal one. The forked lever H then resumes its horizontal position, and the movement of the armature ceases. Four claims are made for this arrangement and for other adaptations to special cases.—No. 4545. March 26th, 1887. 8*d.*

ELECTROMOTORS.—*G. Scarlett, Liverpool.*—The object of this invention is to construct an electromotor which will work without field magnets. A revolving ring or rings of soft iron are employed, which are cut at one or more points, and the gaps thus formed are filled with a connecting piece of non-magnetic material such as brass. On the circumference of each ring is a

Digitized by Google

groove suited to carry a gut band or driving strap. The rings are supported and held in position by flanged rollers. Surrounding the rings are a series of solenoids; the ends of these coils are carried to commutators, which are arranged so that when the ring rotates, one or more of the coils are connected to the actuating battery circuit, and the other coils to the secondary circuit. It is so arranged that the battery current is set up in the coils nearest the ends of the soft iron portions of the annular bar, and the current will therefore cause their magnetisation. As these coils are at the ends of the magnet only, the magnet is propelled forward so as to bring the centre of the magnet into the field of the lines of force. The moment, however, that the magnet goes beyond a coil and enters another the battery current is cut off by the commutator, and is admitted to the one which the magnet is just entering. There is, therefore, a constant struggle on the part of the magnet to get into equilibrium, and a continuous rotary motion is accordingly set up. In the meantime, secondary currents have been set up in the remaining coils, especially in the two immediately following the one through which the battery current is passing. When the battery current is cut off from the actuating coil, a secondary current is generated in it. The secondary currents are picked up and conveyed away to secondary batteries for storage, or may be utilised for driving another ring. If not collected they would soon cause the overheating of the machine. One of the advantages claimed for this machine is that the secondary currents are utilised instead of their being left to neutralise the action of the apparatus. There are three claims.—No. 7021. May 13th, 1887. 8*d*.

Dynamos.—*W. M. Mordey, London.*—In alternate current machines the inventor proposes to employ a field magnet which with a single exciting coil supplies the whole inductive effect; in some cases two such magnets may be used. When applied to armatures of the Siemens type, the whole periphery of the armature is surrounded with iron. Inside this iron ring is placed a magnetising coil, whose convolutions also entirely surround the periphery of the armature; or the coil may be at the side of the armature near its circumference. From the outer iron ring, iron pole pieces project towards the axis; a number of similar magnetic poles are thus produced on one side

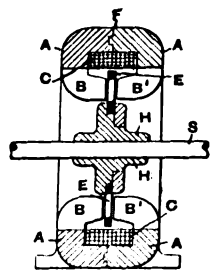


Fig. 1.

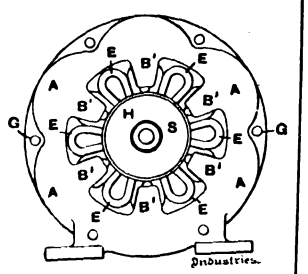

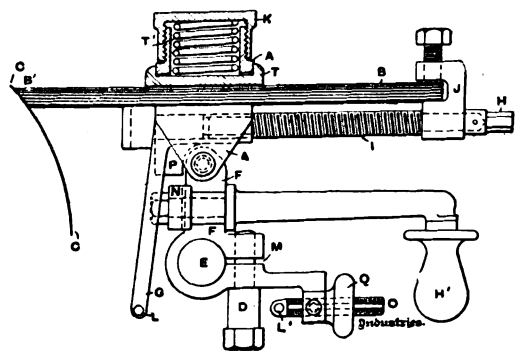

Fig. 2.

of the armature, faced by a number of poles of the opposite sign on the other side. The accompanying figures illustrate a dynamo constructed according to this method. The armature consists of a number of coils E carried by the hub H. The whole circumference is surrounded by the iron ring A, and inside is placed the magnetising coil C. From the outer iron ring the pole pieces B B¹ project. These pole pieces are magnetised by the peripheral winding C. In the case of an ordinary alternate current machine, the number of polar projections on each side of the armature is made exactly half of the coils E, and the enclosing iron E is divided as shown in Fig. 1. The two portions are machined true on the inside faces F, and then bolted together at G after the armature and coil E has been inserted. Several other applications of this principle are described in this patent. Eleven claims are made.—No. 8262. June 8th, 1887. 11*d*.

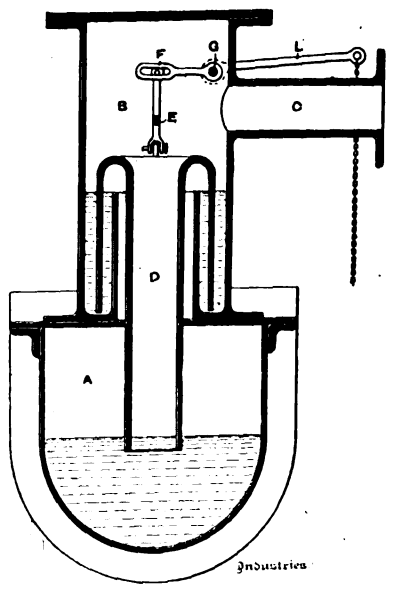
Brush Holders for Dynamos.—*A. P. Trotter & W. T. Goolden, London.*—These holders allow the brush to be traversed in a direction perpendicular to the axis of rotation of the commutator, or at any desired degree of obliquity to the axis. The

curved lines C C denote part of the circumference of the commutator on which the brush B B¹ bears. The fixed part F of the holder is clamped to the insulated arm of the usual brush carrier by means of the shouldered stud D. The movable part of the holder A is secured to the fixed part by the pin N, about which it is free to rock. The lower end L of the arm G, forming part of the movable portion, is connected to the end L¹ of the regulating screw O by a spiral spring, and thus tends to draw the brush on to the commutator, the tension of the spring being regulated by the thumb nut Q. The feed or traverse of the brush is effected by the handle H, which is pinned to the outer extremity of the unthreaded portion of the screw I; the threaded portion engages in a corresponding threaded opening in the movable part of the holder. The backward or forward motion of the screw I imparts a similar motion to the sleeve clamp J. The upper portion of the movable part A is formed as a box for the strong spiral spring T¹, which is held in compression by the threaded lid K. The lower end of the spring T¹ presses on the thickness piece T, and serves to steady the movement of the brush during the traverse, and aids in maintaining a uniform pressure and flexibility of contact on the commutator. When it is desired to lift the brush off the commutator, the handle H¹ is given a quarter turn. By this means the cam piece N is brought to bear against the projection P, and the whole of the movable part A is thereby rocked about its pin, so throwing the end B¹ up and off the commutator. The inventors make one claim for this method of constructing the brush holders.—No. 5186. April 7th, 1887. 8*d*.

CHEMISTRY.

Manufacture of Hypophosphites.—*P. G. W. Typke, New Malden, Surrey.*—Hitherto the phosphoretted hydrogen given off in the manufacture of hypophosphites has been either wasted or converted into the comparatively valueless chemical phosphoric acid. According to this invention, the gases and steam, resulting from the treatment of alkaline earths with water and phosphorus, are first cooled, so as to deposit the greater proportion of water. The gases are afterwards conducted through a tube, which is heated by a furnace, and filled with pieces of unslaked lime. The result of this action is the production of phosphide of calcium. This chemical is converted into hypophosphite and phosphoretted hydrogen by the action of water, and the phosphoretted hydrogen is used again in the same way as before. Two claims are made for this utilisation of the phosphoretted hydrogen as described.—No. 7504. May 23rd, 1887. 6*d*.

Treating Ores.—*J. S. MacArthur, R. W. Forrest, & W. Forrest, Glasgow.*—The ores to be treated by this process may contain lead, zinc, iron, gold, or silver in the form of the sulphides. The ore is first finely powdered and treated with a solution of per-salts of iron at their boiling temperature. Certain of the metals are dissolved as per-salts, and are separated by washing. If lead is present, it is preferable to use hot water to wash out its salts; and if silver is present, a hot solution of common salt is used for the same object. The per-salt of iron becomes partly or wholly reduced to the proto-salt, having given up the rest of the acid to the copper, zinc, lead, and silver. The precipitation of the salts of these metals is effected by running the solutions through a series of tanks. Most of the lead and silver will settle in the first two tanks, and the copper can be precipitated by means of metallic iron. The zinc falls to the bottom on the addition of oxide of zinc or sulphide of sodium. The proto-salt of iron is regenerated for further use by any of the ordinary oxidising or chlorinating processes. In the second stage of treatment the ores are mixed with a halogen per-salt and other salts of iron; the gold is thus converted into a soluble salt, while the compounds of the base metals are prevented from dissolving. Three claims are made.—No. 7278. May 19th, 1887. 6*d*.



Colouring Matters.—*J. Y. Johnson, London.* (*Badische Anilin und Soda Fabrik, Ludwigshafen am Rhein, Germany.*)—In order to prepare a soluble naphthazarine, the inventors take one hundred parts of a paste containing 20 per cent. of dry naphthazarine powder, and intimately mix it with thirty-five parts of a solution of bisulphite of soda of 38°Bé. to 40°Bé. This mixture is then digested in closed vessels at a temperature of 50°C. to 70°C. for a period of eight days, at the end of which time the desired soluble colouring matter is obtained. This invention also relates to an improved mordant for use in dyeing with naphthazarine, viz., the new chromium compounds of naphthazarine. If these chrome lakes are produced within the textile fibre they give rise to shades of colour varying from an intense black to the most delicate grey or slate; they can thus be used in conjunction with other colouring matters for the purpose of toning down the colour. As an example of their action the inventors describe the application of them to woollen goods. One hundred parts of well washed wool are taken and boiled for an hour and a half in water to which has been added about three parts in weight of bichromate of potash and two and a half parts of bitartrate of potash. The wool which has thus fixed the chromium mordant is then well washed and placed in a dye bath. In the bath are contained forty parts of naphthazarine paste of 10 per cent. strength, dissolved in cold water. In order to neutralise the carbonate of lime usually suspended in the water, about one part of acetic acid is added for every thousand parts of water. The temperature of the dye bath is then raised to the boiling point, and there maintained for two or three hours. This process of mordanting may be varied by the application of other mordants, such as chrome alum, or bichromates of potash and soda in combination with sulphuric, tartaric, or oxalic acid; but the above described method is preferable. In preparing the soluble naphthazarine in the commercial form of dry powder, its aqueous solution is either evaporated to dryness, or it is saturated with common salt; in the latter case a precipitate is formed which is collected upon a filter and dried. An analogous result is obtained if the bisulphites of ammonia or potash are employed instead of the bisulphite of soda. The powder of soluble naphthazarine has the appearance of a dark brown powder, and its aqueous solutions possess a brown colour and exhibit a strong bluish green fluorescence. Two claims are made, one for the mordanting process, and one for the production of the soluble naphthazarine.—No. 7833. May 28th, 1887. 6*d*.

Explosives.—*H. H. Lake, London.* (*Wohanka & Co., Vienna.*)—When the nitro derivatives of the hydrocarbons of the aromatic phenol series are dissolved in concentrated nitric acid they yield exceedingly powerful explosives. The disadvantage of these explosives is that they are liquid. The object of the present invention is to transform these liquids into a gelatinous or plastic compound. This is accomplished by the addition of cellulose in the form of fine wood wool, cotton, or other fibrous substances. The cellulose swells up by its contact with the nitric acid, and forms with the explosive a plastic mass like gelatine. Sometimes the cellulose is nitrated before its mixture with the explosive. Two claims are made.—No. 7608. May 25th, 1887. 4*d*.

Printing Ink and Dyes.—*L. A. Groth, London.* (*C. Collin and L. Errani, Paris.*)—The object of this invention is to prepare a black liquid, which shall be antiseptic and insoluble in water, for use as the base of several compositions for dyeing, printing, and varnishing. The different kinds of black known as black aniline, blue black, compound black, and unitarian black, are dissolved in either aniline, nitrobenzine, or phenol. When these colouring matters are dissolved, quantities of rosin, bitumen, or fatty substances are added to the mixture in proportions varying with the purpose for which the compound is used. One claim is made.—No. 17925. December 30th, 1887. 6*d*.

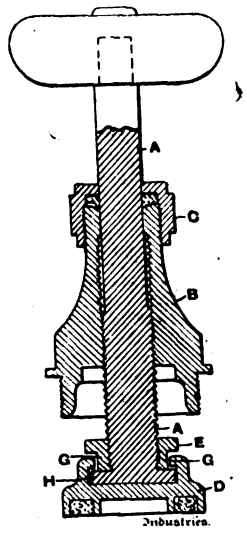
MISCELLANEOUS.

Relieving Gas Retorts from Pressure.—*T. Settle, Huddersfield.*—The accompanying illustration shows a transverse section of the hydraulic main, dip pipe, and bridge pipe. The apparatus consists of the hydraulic main A, upon the top of which is bolted the chamber B; the lower part of the chamber B is annular, and capable of containing liquid. To this chamber is cast the bridge pipe C, which connects the chamber B with the ascension pipe. Within the chamber there is an annular dip pipe D; the outer annulus of this pipe descends and enters the liquid contained in the cup of the chamber B, while the main part of the pipe enters

the liquid in the hydraulic main. The dip pipe is suspended by a strap E, which is connected to a slotted lever F turning on an axis G. The lever L is fixed to the axis G, and a chain hangs down from its free extremity. The liquid is supplied to the cup, and the retort charged; the chain is then drawn down, causing the dip pipe to be withdrawn from the liquid in the hydraulic main so as to afford an unimpeded course to the gas. The pipe may be allowed to dip into the water slightly if a seal is desired. The annular cup will always be supplied with liquid from the condensation of the gas. By this apparatus the retort may be partly or entirely freed from pressure. Three claims are made for the dip pipe, chamber B, and manner of suspending the pipes.—No. 1274. January 27th, 1888. 6*d*.

Jointing Sheets of Metal.—*W. Orr & P. S. Brown, Glasgow.*—The object of this invention is to provide a simple means of securing the sections of sheet metal together, without the necessity of overlapping the edges. The edges, which have hitherto been riveted together, are bent upwards or downwards, and are butted together. Over the downwardly or upwardly projecting parts there is slipped a circular or oval tube, which has a longitudinal slot along the whole of its length. When the edges are so placed, the joint is made tight by the insertion of wedges between the edges of the plate, or by curving the edges of the slot inwards to grip the sheet. The fastening of the sheets, if used for roofing, is preferably in the direction at right angles to the eaves; and the tubes are secured to the purlin bars by bolts and brackets, or they may be carried in slots made in the bars. Several modifications of the tube are described in the specification. Three claims are made.—No. 7280. May 19th, 1887. 8*d*.

Manufacture of Tin Plates.—*A. J. Maskrey, Nant-y-glo, and P. S. Phillips, Crumlin, Monmouthshire.*—The apparatus here described is arranged so that the coating of successive plates is effected in a continuous manner by the aid of two operators, who feed the plates into the bath and remove them from the delivery rollers respectively. The bath is in the form of a rectangular basin with a curved bottom, and is divided by a partition which extends some distance down into the metal. The partition is made hollow, and its internal space is open at the top, so that it can be charged with molten metal. The heat is applied at the feeding side of the partition, and passes through the partition to the other part of the metal, which is covered with grease; if no metal is in the hollow of the partition, the metal on the other side will be cooler. Within the bath there are two or more sets of guide bars of circular curvature sweeping round under the partition; and below these are guide pulleys for an endless chain, which also passes over a chain driving wheel at the top of the bath. Some of the links have studs projecting from them. As each stud presents itself over the top of the bath, the operator places a plate in front of it, and introduces the front edge of the plate between the curved guide bars. The plate then travels through the bath of metal and grease, and is delivered through rollers at the other end in a finished state. One claim is made for this apparatus.—No. 6109. April 26th, 1887. 8*d*.



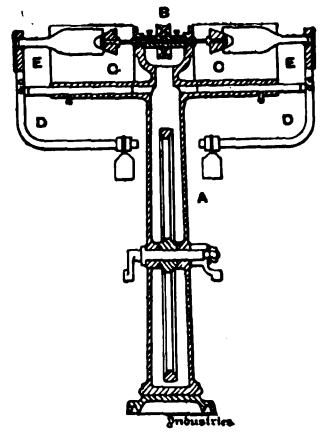
Digitized by Google

CAGE FOR CARRYING FIBRE.—*H. M. Girdwood, Manchester.*—This invention relates more particularly to Patent No. 9270 of 1887, in which is described a method of treating fibres. The cage in which the fibres are packed is made of metal rods, and is preferably in three pieces, consisting of the main portion, the lid, and the dividing portion. The parts are unfolded while the fibre is packed in, and when the movable pieces are fastened down on the main portion, the cage becomes divided into six compartments. The interior divisions are made by a series of metal rods, which are fixed in the main portion and in the lid. Two claims are made for the cage, which is divided into separate sections.—No. 1675. February 4th, 1888. 6*d.*

DISTRIBUTING OIL UPON WOOL.—*P. Bairstow & J. Bairstow, Halifax.*—The object of this invention is to distribute oil and soap suds upon wool whilst it is being fed to the drawing frames or combing machinery. An oil trough is kept supplied in any suitable manner, and inside it is placed a series of cranked tubes; these tubes revolve, and take up the oil and pass it along a second stationary tube above the wool. The stationary tube is perforated, and a circular revolving brush, coming in contact with it, takes off the oil, and throws it in a fine spray among the fibres. The amount of oil distributed can be regulated by driving the feed tubes at a different speed. The inventors claim the combination of the revolving tubes and brush.—No. 6726. May 7th, 1887. 8*d.*

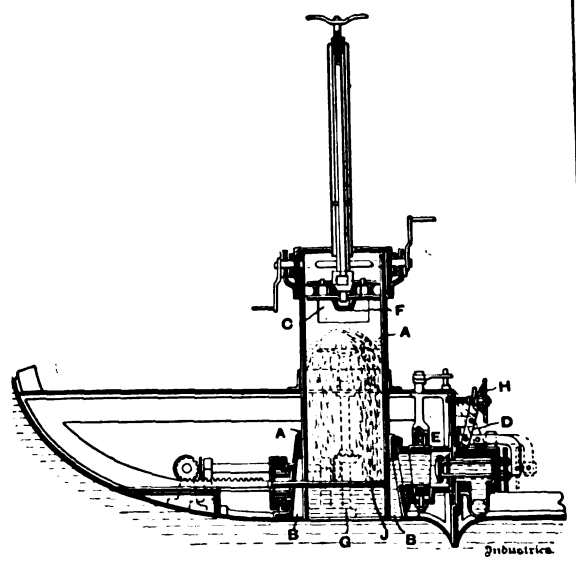
SHUTTLES.—*H. Burgess & T. Burgess, Congleton, and C. Clay, Manchester.*—In looms employed for weaving smallwares, such as ribbons, the axis of the bobbin which carries the weft yarn usually runs parallel to the longitudinal axis of the shuttles; this arrangement requires the use of a shallow horizontal bobbin which carries only a comparatively short length of the weft yarn. In overcoming this disadvantage the inventors place the axis of the bobbin transversely to the axis of the shuttle, so that when in use it will assume a perpendicular position; the bracket which carries the axis and the controlling spring is arranged so as to allow of the free movement of the bobbin, and the bridle is so placed as to take up the slack from the top to the bottom of the shuttle. Five claims are made.—No. 387. January 10th, 1888. 8*d.*

STOP VALVES.—*W. P. Thompson, Liverpool. (The Barnett Brass Company, Mansfield, Ohio, U.S.A.)*—The spindles and valves are attached to each other in such a way that the valve proper can have a rotary motion round the spindle, and can be easily separated for repairs or renewal. The figure represents a section of a stop valve constructed according to this invention. B is the hub of a valve having the usual stuffing box C, and an internal screw thread to receive the corresponding thread on the valve spindle A. The valve spindle has an annular collar F at its lower end, and above the collar is placed a nut E, which can be screwed closely against the upper side of the collar. The valve proper D is constructed with the usual annular groove containing the packing H. An annular chamber is formed in the top of the valve D, and at one side of the chamber is a lateral opening wide enough to allow the collar F to pass into the chamber. The nut E is screwed down in position as shown in the figure, so that neither the nut nor the spindle can pass laterally between



the sides of the passage, and hence the valve and the spindle are securely attached to each other. The desired freedom of movement between the parts is still allowed for, but the possibility of an accidental detachment is reduced to a minimum. The slight rotation of the valve spindle, when the valve comes to a bearing on the seat of the stop valve, causes a like movement of the nut E, and as the nut is so fitted into the opening in the top of the valve that it does not come into contact with the upper projecting rim of the valve D, there is no danger of the nut coming loose. The inventor claims the combination of the collar, nut, annular chamber, and the overhanging rim, as described.—No. 1061. January 24th, 1888. 6*d.*

COTTON GINS.—*A. M. Clark, London. (A. G. Jennings, Brooklyn, U.S.A.)*—In order to increase the efficiency of the ginning process, the inventor makes use of a current of air to force the fibre from the carrier on to the receiving roller. The carrier band is made of wire cloth, and passes over a series of rollers in succession. Two ginning or receiving rollers are caused to revolve in close proximity to the carrier, and are separated from it by a fixed longitudinal grating. The extremities of two air pipes come close up to the carrier, just opposite to the ginning rollers, and the blast of air issuing from them carries the fibre through the grating on to the rollers, from which it is stripped by doffers. The husks and foreign matters are prevented from passing through the grating. Four claims are made for the application of the blast of air for the purpose described.—No. 2592. February 21st, 1888. 6*d.*



GERMAN PATENT ABSTRACTS.

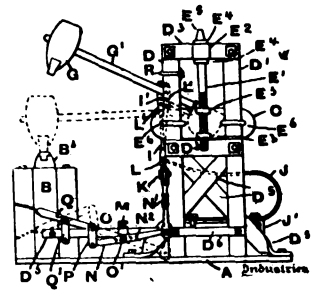
BOTTLE WASHING MACHINE.—*W. A. Zemsch, Worms.*—The bottles are held between elastic cushions C and weighted levers D, fitted with suitably shaped ends E. The cushions are

attached to a spindle which is actuated by means of a belt and the pulleys A and B, thereby revolving the bottles. The inside of the bottles is cleaned by brushes made to the shape of the bottles under operation. These brushes are inserted through a hole in E. The apparatus is arranged to take different sizes of bottles.—No. 42363. May 24th, 1887.

ASH REMOVER.—*Franz Liebler, Kiel.*—This apparatus is intended for removing the ashes from parts of a ship which are below the water line. The ashes are introduced through the door F into the cylinder A, and after shutting F and drawing back

the plate J they are discharged by the piston C. The sea water enters the openings B. The valve E is in communication with a Kingston valve, which is adjusted by means of a lever D and a hand wheel H.—No. 42828. August 3rd, 1887.

UNITED STATES PATENT ABSTRACTS.



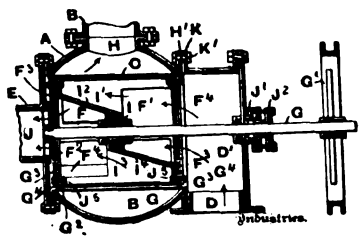
PYROXYLINE VARNISH.—*W. D. Field, Short Hills, New Jersey.*—In making lacquer or varnish of pyroxyline, the pyroxyline is first dissolved in naphtha, and then a menstruum is added consisting of the acetic acid derivatives of the lighter alchohols contained in fusel oil. It is found that this preparation does not dry so rapidly, and the brush marks will thus have time to disappear from the lacquered surface. Three claims are made for the admixture of these acetic acid derivatives with the pyroxyline.—No. 381354, dated 17th April, 1888.

STEAM ENGINE.—*E. A. Moon, Chicago.*—This invention relates to the transformation of the reciprocating motion of the piston rod into the rotary motion of the crank. Two spiral shafts in the form of helicoidal blades revolve in bearings, which are aligned in a parallel direction with the piston rod; two clutches are carried by the piston rod, and gear with the spiral shafts. The blades on the spiral shaft are opposite handed, and the clutches are so arranged that one of them operates during the forward stroke, and the other during the return stroke of the piston. At the other end of the spiral shafts are toothed wheels which gear with a common pinion, and in this way the alternating motions of the spiral shafts are transformed into the continuous motion of the shaft on which their common pinion is fixed. One claim is made.—No. 381160, dated 17th April, 1888.

SCOURING FIBRES AND FABRICS.—*G. Toppan, Salem, Massachusetts.*—The present invention relates to the composition of the bath used for scouring yarns and fabrics. A mixture is made of benzine, mustard seed oil, and an alkali, preferably caustic soda, and the whole is well diluted with water. This bath may be used for any kind of fibre without the fear of any deleterious action on the part of the chemicals. Three claims are made for the composition and for its application.—No. 381444, dated 17th April, 1888.

ORNAMENTING SHEET TIN.—*J. Koebel, Milwaukee, Wisconsin.*—This invention relates to the production of a coloured crystalline surface on sheet tin. The sheet is first heated until the tin begins to melt, and the surface is then cooled by sprinkling cold water upon it or by blowing a blast of cold air over it. The cooled surface is treated with a mixture of nitric acid, muriatic acid, and bichromate of potash. Afterwards cold water and muriatic acid are successively poured over the metal, and after these have been drained off, the same process is performed with a solution of hyposulphite of soda. The object of the invention is then attained. Two claims are made.—No. 381390, dated 17th April, 1888.

FOOT POWER HAMMER.—*C. J. Rundquist, Opheim, Illinois.*—The accompanying illustration shows an elevation of a hammer, and the mechanism employed in actuating it by means of foot power. The handle G^1 of the hammer G is mounted on a rocking shaft, which is carried by vertically adjustable bars and a clamp plate. The anvil is shown at B, and the lever Q is adapted to be moved by the foot of the operator. The levers P N K transmit the motion to the rock shaft, and cause the



hammer to rise; the weight of the hammer causes it to fall. The handle is adjustable, and the rock shaft may be adjusted vertically by means of the screw E^1 and plate C. The plate C slides up and down the standards D D^1, and carries the rock shaft and clamp plates with it when the screw E^1 is turned. The length of the foot leverage may also be varied by means of the fulcrum O^1 being inserted through the several holes N^2 in the lever N. Thirteen claims are made.—No. 379818, dated 20th March, 1888.

THREAD GUIDE FOR LOOM SHUTTLES.—*T. J. Mayall, Reading, Massachusetts.*—The thread passage in the shuttle is formed by bending a piece of sheet metal strip back upon itself, and fixing it on the shuttle so as to form the walls of the thread space. These two parallel walls have slots in them, through which a spring piece passes. The spring holds the thread down, and a button resting upon the spring affords the means of retracting the spring so as to allow the entrance of the thread. There are three claims.—No. 381402, dated 17th April, 1888.

CARDING ENGINES.—*E. Wright, North Andover, Massachusetts.*—Certain improvements are here introduced into the construction of the mechanism for operating the doffer combs of carding engines. The driving shaft has its inner end enlarged and provided with two or more holes at different distances from the centre. The purpose of the holes is the reception of a shank, to which is attached a sleeve. The sleeve receives the end of an arm, which forms part of a hub on the comb shaft. The amount of motion communicated to the comb is thus made to depend upon the hole into which the shank is inserted. There are two claims.—No. 381516, dated 17th April, 1888.

HYDRAULIC VALVE GEAR.—*R. L. Teed, Chicago.*—The accompanying illustration shows a section through the rotary water valve. The water supply enters at D, and the water may be made to leave either at E or B. Inside the casing A is placed an inner casing C, in which are two ports communicating with H. The rotary valve F is mounted on the spindle G, and is

made to fit tightly against the inner casing. The central partition I divides the interior into the two spaces F^1 F^2, and the passages I^1 I^3 allow the water to travel through. The rotation of the wheel G^1 causes the valve to either close the ports or to place either of the spaces H or J in communication with the supply. The arrows indicate the course of the water. Six claims are made for this valve.—No. 379617, dated 20th March, 1888.

AN IMPROVED LOOM.

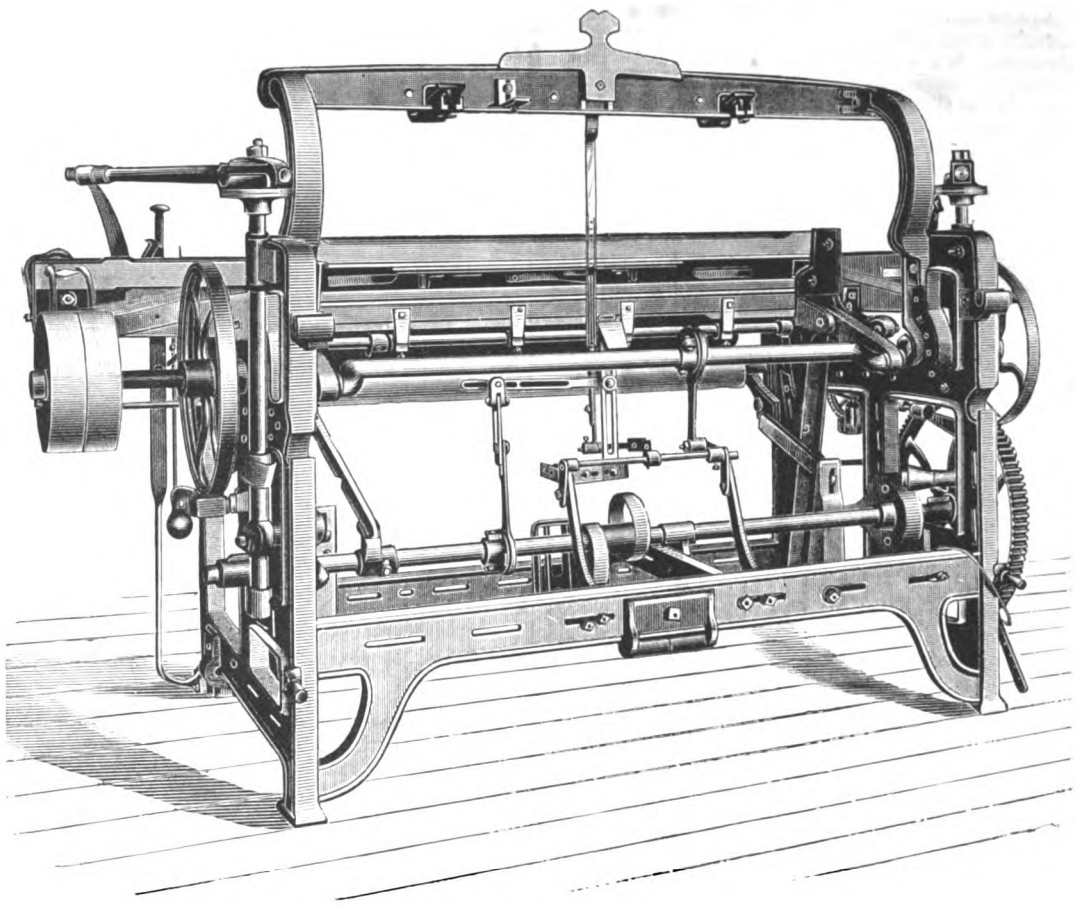
THE accompanying illustration represents a loom fitted with Simpson's patent selvedge motion, the object of which is to provide a ready means whereby two pieces of cloth can be easily woven on the same loom. From the fact that each piece is connected by the weft, and can be easily separated, they are technically known as "splits." There are several prior inventions for this purpose, all of which are defective in one or more points, and it is claimed for the motion we are now describing that many of the defects of its predecessors are remedied. The objects of such a motion are to so manipulate the leno threads —that is, those in the warp which form the selvedge— that they may be securely fastened, and fraying out be completely avoided. These leno threads are usually doubled, and they can either be wound on the beam in the ordinary manner, or, as in this case, special provision can be made by winding them on to separate bobbins placed in some convenient position. The latter is the preferable course, as it permits of the change from a narrow to a broad piece to be more readily effected. Two of the leno threads are passed through eyes formed in a vertical lever which oscillates laterally, and which derives this movement from an eccentric fixed on the tappet shaft. The eccentric being adjustable, any amount of throw can be given to the lever as desired. A similar eccentric is fixed on the crank shaft, and drives two vertical rods with eyes at their upper extremities, known as reed hooks. These hooks have a vertical motion only, and are employed to form the shed, which can be varied by adjusting the eccentric. The space left between each piece is one dent only, so that it will be seen that this mechanism occupies very little room, the splitting of the warp being effected by the rod carrying the reed hooks. Thus one pair of ends have the necessary sideward movement, and the other the vertical movement, to permit of the locking of the weft; and the general effect is that the weft is completely wrapped round each pair of leno ends, which are thus securely fastened. This movement really requires diagrammatic representation to make it quite clear, but the effect is as stated. It may be noted that it is not necessary to cut down the healds, which can be left in their ordinary form, and by the simple removal of a bracket the loom can be weaving broad cloth in less than five minutes. Among the advantages which are claimed for this loom is one which we think will be generally admitted, viz., its adaptability. By the use of some such motion a manufacturer is not limited in the class of cloth he can weave, but can take orders for such broad or narrow widths as may be required. The extra first cost of a broad loom is very slight, and would not seriously militate against its adoption, while in many ways it would be decidedly advantageous to use wider looms. Indeed, if this freedom of choice were left to manufacturers, there is little doubt that they would readily accept the wider loom, as in that way space, wear and tear, and rent would be saved. We may add that the motion in this case is positive, and does not depend on any springs for its efficiency. The makers of this loom are the "Simpson" Patent Selvedge Motion Company, Springfield Bridge Works, Manchester.

THE INSTITUTION OF MECHANICAL ENGINEERS.

AN ordinary general meeting of this Institution was held at the Institution of Civil Engineers on Thursday evening, the 3rd inst., and on Friday afternoon, the 4th inst., the time having been fixed at half-past two for the second day, on account of the annual dinner, which was held in the evening.

The president, Mr. E. H. Carbutt, in opening the meeting referred briefly to the Architects' Registration Bill, and expressed the thanks of the Council to those members who had taken an active part in opposing this Bill, either personally in Parliament, or by writing to their members of Parliament. The Bill was most mischievous and totally unnecessary, and the President hoped the gallant member who had introduced the Bill would profit by the experience of its sudden collapse, and not interfere with the engineering profession in future. The President next referred to the accession of thirty-six new members, among whom he was pleased to see the names of Dr. Werner Siemens and Mr. Frederick Siemens. He also drew the attention of the meeting to the Paris Exhibition of next year, and regretted that the Government, who on the last occasion had spent about £67,000 in organising an adequate representation of British industry, refused on this occasion to take any official part in this great undertaking. Mr. Carbutt pointed out that it would be a grievous mistake for our engineers and manufacturers to abstain from exhibiting at Paris, especially as many persons from South American countries will visit that exhibition. Those countries are capable of great development, and the Paris Exhibition will be an excellent opportunity for initiating business relations with them. The President, in calling upon the secretary to read the third report of the Research Committee which dealt with experiments on the friction of a collar bearing, stated that Sir Henry Bessemer had promised to put his experience on the friction of high speed vertical shafts at the disposal of the committee, if they should continue their experiments. As we give this paper *in extenso* in another part of our present issue, a very brief abstract of it will suffice in this place. The experiments were made with a friction apparatus specially designed by the committee, and consisting of a steel ring of 13in. mean diameter, held stationary between two revolving rings of gun metal. The surfaces were oiled at the minimum rate of lubrication with which the bearing could work safely, but were not running in an oil bath. The pressure between the surfaces was produced by a spiral spring, and measured by the axial length of this spring, which could be increased or reduced at will by means of a screw and nut. The steel ring was prevented from revolving by a lever on which the twisting moment due to friction was measured, and this twisting moment, the speed, and the pressure between the surfaces were the experimental data. The general conclusions arrived at by the committee were: First, that this kind of bearing is very inferior to a cylindrical journal in its power of carrying weight; secondly, that the co-efficient of friction is much higher than for cylindrical bearings, and that the friction follows more nearly the law of the friction of solids than that of liquids; thirdly, that the co-efficient of friction is independent of the speed, but diminishes somewhat as the load is increased.

A letter from Mr. Alexander Turnbull, of Glasgow, was then read by the Secretary, in which the writer drew attention to the fact that the result as given in Tables XIV. and XV. are not very satisfactory, on account of their irregularity. He attributed this to the complication of the apparatus used in the experiments, which had too many moving parts, and about one dozen points or surfaces which must be in contact before an accurate measurement can be taken. The writer had himself designed a more simple machine, which is intended to obviate these difficulties.



Mr. Tomlinson, the chairman of the committee, defended the design of the apparatus used. The irregularities mentioned by Mr. Turnbull were simply due to differences in lubrication. It would have been very easy to so adjust the lubrication for each experiment that the curve Fig. 11 should not contain the kink in the middle; but he thought the members would not thank the committee if they had adjusted the conditions of their experiments with a view to get a pre-conceived result. The committee are now designing a machine for testing the friction of pivot bearings.

Mr. F. Smith, of Manchester, called attention to the fact that one most important point had not been touched in the paper, viz., the quality of the metal used for shafts and bearings. He had found that with soft steel the danger of seizing and tearing of surfaces is exceedingly great, and the difficulty could only be overcome by a large increase of surface; and failing this, by using hardened steel, working on a surface of dense cast iron, or, better still, by using hardened steel working on hardened steel. He mentioned one case where a vertical shaft of 2¼in. diam. and 40ft. long was working satisfactorily on a pivot bearing of only 2¼in. diam. This pivot had to support the weight of the whole shaft, three couplings, and several heavy wheels, and the speaker attributed the success to the employment of several hardened steel washers interposed between the ends of the shaft and the bottom of the bearing. A central channel was drilled through these washers with oil channels radiating outwards on the face of each washer, and the whole was working in an oil bath. The object of employing several washers was to allow them to rotate at different velocities, and thus divide the speed between them. A similar arrangement is also used in drilling machines, where the pressure per square inch is exceedingly great.

Professor Unwin thought the reason why a collar bearing would carry more weight at low speeds than at high speeds was on account of the temperature. It is evident that heat must be accumulated in every bearing, and the latter can only work safely as long as the rate at which the heat is carried off at a moderate temperature is equal to the rate at which that heat is generated. Now, where the speed is fast, the energy transformed into heat must be greater than where the speed is low, and, therefore, the load per square inch cannot be so high in fast running shafts. He thought it remarkable that the friction was independent of the speed, but not of the pressure. It would generally be supposed that the rate of lubrication must in some way be connected with the speed.

Mr. Schönheyder thought the method of using water for cooling bearings a barbarous one, and he objected to its having been adopted in these experiments, as it altered the conditions under which collar bearings should work in practice. He also objected to the journal being stinted of oil. A thrust bearing in a ship would run

AN IMPROVED LOOM.

GENERAL VIEW.

Digitized by Google

in an oil bath, and yet the lubrication was very economical, because the oil could be used over and over again. It was remarkable to find that whereas a cylindrical journal could carry from 400lb. to 600lb. per square inch, this collar bearing carried only about one-tenth of this pressure safely.

Professor Barr explained the difference between the two kinds of bearing by referring to Professor Reynolds' theory that in the case of brasses and a cylindrical shaft where the radius of the former was larger than that of the latter, the oil was carried by the shaft from the free space at the side until it was jammed between the brass and shaft, where they came into contact with one another. He suggested an analogous arrangement for collar bearings and pivots consisting of a groove tapering to nothing in the face of the collar or bearing, so as to jam the oil between the surfaces. In the machine which had been used no provision was made for altering the pressure during a run, and the speaker suggested the employment of a water pressure diaphragm such as was used in the Emery testing machine. It was desirable to know where the oil appeared, and whether it ran from the inner to the outer circumference or *vice versâ*.

Mr. Greig contended that bearings should have a surface proportional to the speed, and that it was of great importance that air should be admitted, in order to keep the bearings cool and to circulate the oil. He considered some of the theories which had been enunciated as quite fallacious, and caused considerable amusement by stating that, "in fact, there was no theory about a bearing."

Mr. Wickstead further illustrated Professor Reynolds' theory as to the carrying forward of the oil into the space between the cylindrical journal and the brass, by pointing out that the journal will only carry 100lb. per square inch when the lubricant is applied on the pressure side, whereas it will carry 600lb. when the lubricant is applied on the other side. Allowing for the reduction of area of contact due to the difference in the radius of journal and brass, the actual pressure would probably be 1200lb. per square inch. The collar bearing tested by the committee failed at 80lb., but in practice collar bearings were loaded to about four times this amount. In a drilling machine, for instance, the shoulder of the spindle had about 2 sq. in. area, and the pressure on the drill might be 6 cwt., or about 336lb., per square inch. Yet it worked with hardly any attention, and with no special lubrication. This was due to the low speed of about 20ft. per minute, and to the interposition of a hardened steel washer, revolving at half the speed of the drill. In another case, that of a screw displacer on a testing machine, the pressure at the end of the operation amounted sometimes to as much as half a ton per square inch; but here the work was intermittent, and a considerable amount of heat was generated. He suggested that the committee should continue their experiments with a collar bearing more nearly resembling that of a screw propeller shaft bathed in oil.

Mr. Scott Moncrieff complained that the report was not at all explicit as regarded the question of lubrication, and considered that details should be given as to the amount of lubrication required to produce certain results. He and the late Mr. R. D. Napier had gone into the question of friction at the time that the latter was working out his differential clutch, and they found that there was a great difference in the effects of lubrication with vegetable and with mineral oils.

Mr. Holroyd Smith had used washers for turbine shafts, and these had proved successful in one case, but not in another. His theory had been that they caused a reduction of speed, but this proved not to be always the case, and he thought that possibly the pile of washers acted as a kind of self adjusting apparatus like the onion bearing described by Mr. Davey at their last meeting. To facilitate lubrication, he suggested that the collars, instead of being rounded off in the corner, should be undercut; he had also found it advantageous to use collars which, instead of having their working surfaces at right angles to the shaft, had them in the shape of very flat truncated cones. This arrangement facilitated the circulation of the oil and compensated for cross strains.

Mr. D. Adamson regretted that the paper contained no practical advice. The lubricant should be chosen with reference to the speed at which the shaft worked. For light spindles, running at 10,000 revolutions per minute, thin mineral oils were best suited; but for heavy, slow-running shafts, the thick vegetable oils or animal fats were preferable. He knew of a case where a weight of 10 tons was carried on a 5in. shaft, the area of the bearing being only 20 sq. in. To facilitate the carrying of the oil between the surfaces in cylindrical journals, he had found it useful to file a flat on the journal, the flat being $\frac{1}{4}$in. wide for every inch in diameter.

Mr. Paget drew attention to the fact that this and the previous investigations of the committee had considerably altered our views of friction, and he looked upon the experiments as showing a result which was half way between the friction of fluids and the friction of solids. It was most desirable that bearings should be so constructed as to come entirely within fluid friction. What was wanted in a collar bearing was that it should float on oil.

Mr. Mair, in reply to Professor Barr, pointed out that the ring did not revolve and was very narrow, in consequence of which it was difficult to get the oil from the inside to the outside, as there was little centrifugal force. The ring was of mild Landor-Siemens steel. If the committee had set themselves the task of investigating the behaviour of different materials in this bearing their labours would have been indefinitely prolonged, as the choice of materials was practically unlimited.

Mr. B. Tower, in replying to the discussion, said that the diagrams obtained by the committee were on the whole more regular and satisfactory than many of the diagrams usually obtained in experiments on friction. He considered it as quite certain that the readings of the pressure were practically correct. The compression of the spring was ascertained by dead weights, and always found to agree within 2lb. for the same reading of the micrometer. He had no doubt that the heat developed is the determinant factor in the load which can be put on to a bearing, and he did not think that 80lb. per square inch was so small a safe load as some speakers had stated. He might mention that Mr. Thorneycroft loaded the thrust bearing of his torpedo boats with only 50lb. per square inch. With regard to Professor Barr's suggestion that the load should be varied during the run, he might state that the committee had already considered this matter, and determined in their future experiments to use an arrangement not unlike that suggested.

The next contribution read referred to a

Description of the Emery Testing Machine.

By Mr. Henry R. Towne, of Stamford, Connecticut, U.S.A.

We shall in a future issue reprint this paper with illustrations; but to enable our readers to follow the discussion, we give herewith a short abstract.

This machine differs from all its predecessors in two important points, the first being an arrangement of hydraulic chambers and diaphragms capable of receiving without injury pressures and shocks of great intensity, and transmitting the pressures without loss to a convenient point for measuring and recording; whilst the second point consists of a new method of suspending or supporting a vibrating lever either on a fixed abutment or on another lever in the same system in such a manner as to eliminate friction. The machine consists of the usual hydraulic cylinder, but has improved grip boxes. The stress is put on the specimen in the ordinary way by hydraulic power; but instead of directly measuring it by levers, it is made to cause a hydraulic pressure within a chamber provided with a diaphragm, and the pressure is transmitted to a second smaller chamber and diaphragm, which form part of the weighing apparatus, and may be situated in the office or at any other convenient point. The large hydraulic chamber is technically termed the "support," and the smaller hydraulic chamber the "reducer." The acting area of the liquid in the reducer is less than in the support in the proportion in which the load on the specimen is desired to be reduced before it is received upon the beams in the scale case where it is weighed. In the machine described the reduction is as thirty to one, and the maximum load on the large support is 300,000lb. The diaphragms are of very thin sheet brass, and the motion of the piston of the support is less than ·001in., whilst the free motion of the diaphragm is ·1in. The film of liquid in the support and reducer is exceedingly thin, being only about ·015in. in thickness. In the scale case, which contains the weighing mechanism, the pressure transmitted from the reducer is received at one end of a system of levers, and is measured by weights. These weights are applied from the outside by means of two handles in a most ingenious way; but without illustrations it would not be possible to give a clear description of this part of the machine. There are three levers. The first lever taking the load has a ratio of twenty to one, the second lever has a ratio of twenty-five to one, and is connected to a third lever or indicator bar, the arms of which have a ratio of forty to one. The multiplication of motion is, therefore, 20,000 times that of the reducer piston, and 600,000 times that of the piston in the main support. A movement of one six-millionth of an inch at the specimen produces a motion at the indicator point of $\frac{1}{10}$in., which is easily visible. The levers, instead of being supported on knife edges, are connected by thin plates of tempered steel. These fulcrum plates are used in tension where the load is small, as in the indicator lever; but in compression where it is great, as in the first lever. When in tension, the thickness of the fulcrum plates varies from ·004in. to ·006in., and when in compression it varies from ·01in. upwards. The fulcrum plates, when in compression, are forced into grooves planed in the levers, which they unite; when used in tension, they are changed in position, and the maximum working load on the fulcrum plates is limited to 50,000lb. per square inch. Each fulcrum plate offers a slight elastic resistance to bending, but this resistance is balanced by certain poise weights. The machine is arranged for testing specimens for extension, compression, and transverse strains.

The meeting was adjourned after the reading of this paper.

At the meeting on the following day Mr. Wickstead explained the diagrams of the Emery testing machine, and some conversation ensued on the proposal of Mr. Martin to postpone the discussion of the paper until the members should have had an opportunity of seeing the machine at work, which is now being erected, and will be on exhibition next month, at 30, Kirby-street, Hatton Garden. The President, however, with the concurrence of the majority, decided that the discussion should be taken, and if desired the subject might be re-opened at the autumn meeting this year in London.

Mr. Walker did not think that the Emery machine was superior in point of accuracy to the better kind of testing machines now in use; but he admitted that for very great stresses, such as 400 tons to 500 tons, there might be an advantage in the adoption of the hydraulic support and reducer. All testing machines gave comparative results, and a skilful operator could very materially modify the indications of the machine, and this objection would apply equally and perhaps more so to the Emery machine.

Mr. D. Adamson did not think that hydraulic gauging was compatible with a high degree of accuracy. He himself had a machine in which there were two gauges, but as one was accidentally broken he sent it back to the maker, and when it was returned its indications did not agree with the other gauge. He sent it again to the maker to be re-calibrated, and yet the indications did not agree, whereupon the maker asked him to send him both gauges together and he would make them agree. This evidently proved that hydraulic gauges were not absolutely reliable. The speaker thought the Emery machine a good testing machine for comparative work, and he approved specially of the grip boxes, which were a valuable feature of the design. Levers with short fulcrums were objectionable, and it was preferable to employ multiple levers, the shortest fulcrum of any lever not to be less than 6in. With such a system, when the registering lever has moved $\frac{1}{10}$th of an inch, an extension of $\frac{1}{1300000}$th of an inch of the test piece can be accurately ascertained. The speaker did not think knife edges applicable to very great forces, and he suggested that it was high time we had a national testing machine of sufficient power that a 5in. or 6in. bar could be pulled asunder. It was a different thing to test a specimen of half a square inch section and one of 10 or 20 square inches, as in the latter case, especially if the metal is ductile, the outer skin is stretched before the strain reaches the inner portion of the specimen.

Mr. Stanger, of the Chemical Laboratory and Testing Works, in Broadway, Westminster, considered the Emery machine a splendid device to overcome what did not exist, viz., the friction of knife edges. In a 50-ton Wickstead machine which he has at his laboratory there is practically no friction in the knife edges, and he had as yet detected no alteration in the machine. When the short end of the lever is loaded with 50 tons, and is balanced by the moving weight, he could move the lever by applying pressure with one finger only at its short end.

Professor Barr, although admitting that the details in the Emery machine were admirably designed, pointed out that it had the radical defect of too great a multiplying power. For a dead weight weighing machine such multiplication was not objectionable; but the testing of specimens is not an operation involving merely static strains, it is a dynamical process. For commercial purposes tests must be made with reasonable speed, and assuming that a sample having 3in. extension is broken asunder in a quarter of an hour, the rate is 1in. in three hundred seconds. To prevent the levers acquiring too high a velocity, it is necessary to continually adjust the poise weights whilst the test proceeds, and if the operator were to neglect this adjustment only for one second, the indicating point—provided the system were free from inertia—would acquire a very considerable speed. As, however, the system has inertia, the point does not acquire this speed, but the strain due to the extension remains unrecorded. He also pointed out that the connecting pipe between the support and the reducer, which is only one-tenth of an inch in diameter, is too small to allow of the ready flow of liquid which, for the example just given, should take place at a velocity of 62in. per second. He commended the design of the fulcrum plates, but did not think that knife edges were so bad as made out by the author of the paper. An ordinary chemical balance will usually weigh with an accuracy amounting to the $\frac{1}{100000}$th part of the weight applied, and, in his opinion, the Wickstead machine should be equally accurate. In one of these machines he had inserted a specimen 9ft. long and loaded it to 43 tons, and when in this condition he applied a weight of 1lb. to the short end of the lever, he could make the latter move. The advantage of the Wickstead machine was that the weight could be

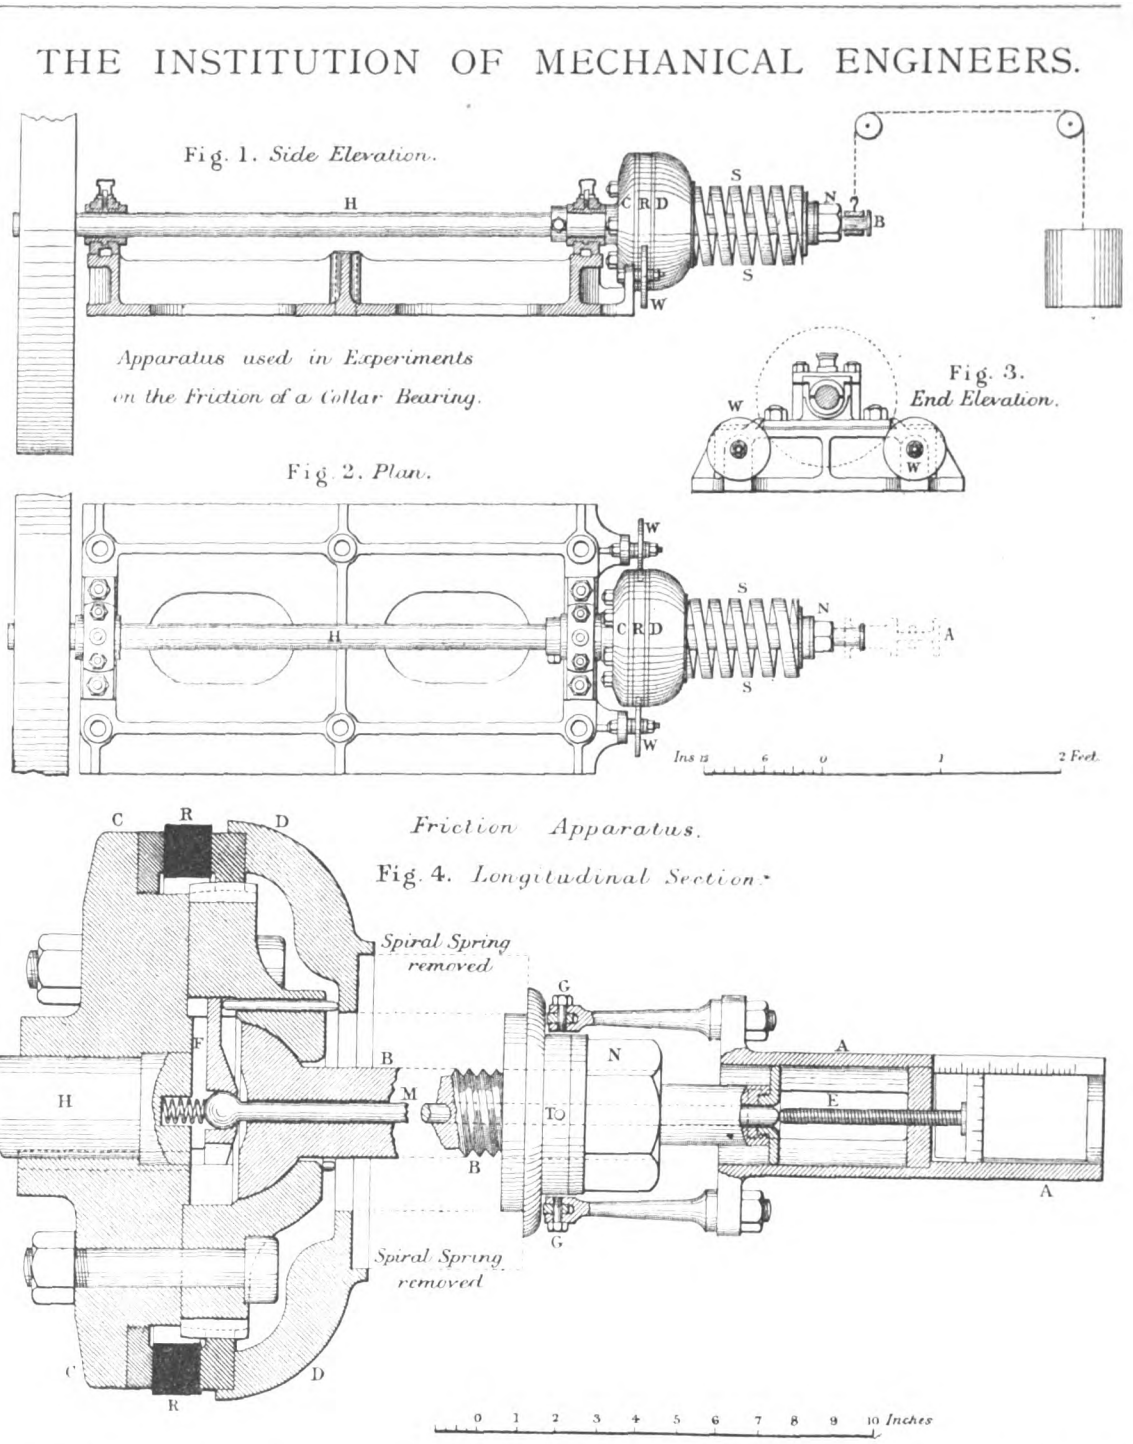
Digitized by Google

kept sliding along the lever during the time the tests proceeded, whilst the lever was kept floating freely. The defect of the Emery machine, due to the inertia of the multiple levers, is, however, not apparent when the machine is used for testing ductile materials, because near the breaking point the stress curve is nearly flat, and only slight variations of strains occur. He regretted that Mr. Emery had not designed his machine with an autographic recorder.

Mr. Paget thought that the diaphragm of the Emery machine was not an objectionable feature. As a matter of fact, in aneroid barometers, which remain in perfect working order for many years, the same device was employed. The introduction of a liquid to transmit the stresses was a good feature. In ordinary testing machines, at the moment of rupture of the specimen, there is always a great jerk; but with water or other almost non-elastic liquids, no shock or jerk would be felt.

Mr. Wickstead hoped that the discussion would be adjourned, and that thereby time would be given to the author to answer certain questions which he should like to put to him. One was whether the machine had been rated for different temperatures, also whether the rating had been done with dead weights. He noticed that in the paper it was mentioned that a special rating machine was employed, which itself had been rated with dead weights; but it was possible that from various causes the condition of the rating machine became altered, and thus the indications of the large machine might be inaccurate. He did not think that the ordinary testing machines in use in this country were so inaccurate as some speakers seemed to imply. When steel makers were dependent upon accurate tests for getting their material accepted, it was clearly of the highest importance that the machines they employed should be as accurate as possible. At the Consett Iron Works, one of his machines had been in use five years. It is possible to test with this machine at the rate of thirty specimens per hour, and this machine has actually broken 250,000 specimens since it was erected. The machine is rated once a year with dead weights, and no alteration has yet been observed in it. With the large multiplication adopted in the Emery machine, great skill is required on the part of the operator so as to obtain an exact record of the load, and a clever operator could catch up the varying loads, and thereby make the machine record almost any result. He did not think the machine stiff enough for compression tests. The stress in this case would pull the two standards out of line.

Professor Unwin, who had specially gone over to Paris last year to see an Emery machine, spoke highly in favour of its accuracy. He had at the Central Institution two Wickstead machines which were very accurate; but the Emery machine surpassed them, as a chemical balance surpassed a pair of grocers' scales. When he saw the machine at work in Paris, the pressure was applied by an ordinary Worthington pump, and the indicating lever, which was kept floating during the whole time of the test—which might have lasted about ten minutes—never reached the top or bottom stop. The reason of the lower accuracy of the Wickstead machine was, in the speaker's opinion, the arrangement of the movable weight, which rolls on a path, which in a scientific instrument must be described as rough, although as a piece of practical engineering it was perfect. The Emery machine can be fitted with an autographic recording apparatus.



The next subject on the list was a supplementary paper on "The Use of Petroleum Refuse as Fuel in Locomotive Engines," by Mr. Thomas Urquhart, the reading of which was, however, adjourned till the next meeting of the Institution.

THIRD REPORT OF THE RESEARCH COMMITTEE ON FRICTION.*

Experiments on the Friction of a Collar Bearing.

Description of the Apparatus.—As shown in the accompanying illustrations, the machine with which these experiments were tried consisted of a steel ring R (Figs. 4 and 5), of rectangular section, which was pressed between two cast iron discs C D. The annular bearing surfaces of the discs were covered with gun metal, and were 12in. inside diameter and 14in. outside, giving on each disc an area of exactly 40 sq. in., after deducting the oil channels. The pressure was applied by a large spiral steel spring S, one end of which abutted against the front disc D, while the other end pressed against a nut N on a central bolt B connected with the back disc C. Screwing up the nut N compressed the spring S, and tended to pull the two discs together, causing them to press the ring R between them. The bolt B was connected with the back disc C by a ball and socket joint, so as to insure the pressure being distributed uniformly all round the ring. The back disc C was keyed on the end of a horizontal rotating shaft H, and drove the front disc D by means of four feathers engaging in four notches, in such a way that the front disc D, though compelled to rotate with its fellow C, was free to move in any other way relatively to it. The two discs rotating together, and pressing on the steel ring R, tended by friction to carry it with them, but were prevented from doing so by a horizontal lever L (Fig. 5) attached to the ring. The holding force on the end of the lever being measured by a spring balance, showed the amount of friction between the ring and the discs. The ring was held concentric with the discs by resting on two friction wheels W (Figs. 3 and 5), because any shoulder on the discs for this purpose was inadmissible, as introducing another kind of friction. The overhanging weight of the spring S and bolt B, which would have tended to relieve the pressure on the top of the ring R and increase it on the bottom, was taken off by a counterbalance weight, on the end of a rope that passed over two pulleys and was attached to a brass collar (Fig. 1), in which the end of the bolt B ran as in a bearing. This arrangement, while carrying the overhanging weight of the spring and bolt, allowed them to run a little out of truth if the spring required it. The true measurement of the length of the spring S, for the purpose of ascertaining the pressure exerted by it, was a point which required special attention. The bolt B had a hole drilled up its centre, along which passed a freely fitting measuring rod M (Fig. 4). The outer end of this measuring rod was flush, or nearly so, with the end of the bolt; the inner end was ball and socket jointed to a three-toe foot F; the point of each toe pressed on one end of a small steel rod, which passed freely through a guiding hole, its other end abutting against the back of the front disc D, immediately behind the seat of the spring S. Thus the three steel rods touched the back of the seat of the spring at three points, and the average of their measurements was delivered to the measuring rod M by the three-toe foot F. All the points of this system were kept in contact by a small spiral spring (Fig. 4) pressing with a definite force behind the ball of the measuring rod M. The position of the outer end of the main spring S was defined by two studs T (Fig. 4) projecting diametrically opposite each other from the washer, which was between the nut N and the end of the spring S. These two studs were touched by two notches in a gimbal ring G, by which their position was averaged, and were connected with a frame A, containing a micrometer screw E. The true length of the spring S was obtained by screwing up the micrometer screw E until its point just touched the point of the measuring rod M. The frame A, containing the micrometer screw, being rather delicate, was removed while an experiment was being made, and was applied only when an alteration or adjustment of the force of the spring S was required. It will be observed that this measuring system was entirely free from any strain applied to the spring, and also from any alteration of zero caused by the wear of the working surfaces. The scale of the spring S was found by putting the apparatus in a vertical position, and hanging weights on the driving shaft H (Fig. 1), and then reading off the micrometer. The weights corresponding with the arbitrary divisions of the micrometer were thus ascertained. The scale of the spring was about 7000lb. per inch. The micrometer screw had thirty-five threads per inch, and its head was divided into tenths and hundredths of its circumference; thus 100th of a turn of the screw was equal to about 2lb., and in testing the spring it was found that on repeating a test the reading of the micrometer could be depended on repeating itself within about that amount.

Lubrication.—The method of lubrication adopted was one which is in practical use for collar bearings, and which seemed by the light of our previous experiments to be a good one. It consisted of four grooves cut in each face of the ring R (Fig. 5), $\frac{1}{4}$in. wide and $\frac{3}{4}$in. long, arranged in a diametrical direction and so that each end of the groove was $\frac{1}{4}$in. inside the edge of the bearing surface. From each of these grooves there extended in the direction of motion of the surfaces a shallow groove about $\frac{1}{10}$in. wide and of a serpentine form, tapering away to nothing in about $3\frac{1}{2}$in. length. These grooves were each supplied by a pipe P, into the mouth of which oil was dropped from a small cock connected with an oil tank K, so that the rate of supply to each set of grooves was easily seen and regulated, and uniformity of supply was secured. As we were led to expect by our previous experience, the magnitude of the friction depended considerably on the rate of lubrication; but we soon found a minimum rate of lubrication with which the bearing would work safely, such that, if the lubrication was less, the bearing would show signs of seizing by rapid variations of friction and

by a jerking of the lever; and if it was much more, the friction, though less, was not reduced in proportion to the increase of the oil supply, and consequently it might be assumed that the oil was being wasted. This minimum safe rate of oil supply, with which the friction recorded in the tables corresponds, varied from 60 to 120 drops per minute for both faces, the quantity varying with the speed and load. The oil used throughout was a mineral lubricating oil.

Results of the Experiments.—The machine was run for a week with varying loads, in order to bring the surfaces into a proper working condition before the experiments recorded in the tables were begun. The experiments were tried in the order shown in Table I., the variations of load being run through with the lowest speed first, then with the next, and so on till the highest speed was reached. Except with the lowest loads, it was found impossible to keep the bearing cool without a little water running over it. The friction given in the tables is that of one face of the annular bearing surfaces, at the mean radius of the face, viz., 6½in. It will be seen from Table I. that the revolutions per minute were not very constant, owing to the varying speed of the shafting by which the machine was driven. The variation in speed, however, was but small in each individual experiment, not amounting to more than 1 per cent. above or below the speeds given in Table I. In order that the results might be plotted on a diagram, it has been necessary to reduce the results to regular speeds at regular intervals by interpolation. The speeds taken were 50, 70, 90, 110, and 130 revolutions per minute; and the results so reduced are given in Table II., from which is plotted the diagram shown in Fig. 10. When examining this diagram, it must be remembered that the friction varies somewhat with the rate of lubrication, and that the minimum safe rate of lubrication is not very exactly defined: this must explain one or two slight irregularities in the diagram. For instance, with loads of 1200lb. and 2400lb. there can be no doubt that at fifty revolutions the rate of lubrication was too great, and the friction consequently somewhat too small; and that, if the experiments were repeated, there would be no difficulty, by reducing the oil supply, in bringing the friction more nearly to agree with that of other speeds. But in these experiments all such adjustments were carefully avoided, as tending to deprive the experiments of value. Nevertheless, in the majority of instances the results are extremely well defined, and point to the fact that the friction is independent of the speed. For instance, with a load of 1200lb. four different speeds—viz., 90, 110, 70, and 130 revolutions per minute—give the same friction so nearly that the greatest variation from the mean is only 2·19 per cent. With a load of 1800lb. four different speeds—viz., 130, 90, 50, and 110 revolutions—give the same friction so nearly that the greatest variation from the mean is only 2·57 per cent. With a load of 2400lb. and three different speeds—viz., 70, 110, and 90 revolutions—there is a variation of only 2·29 per cent. from the mean friction. Again, with a load of 3000lb. the greatest variation from the mean with five speeds—viz., 130, 110, 90, 50, and 70 revolutions per minute—is only 2·12 per cent. The above speeds are given in the order of the magnitude of the friction; and in these small variations it does not appear that there is any well defined connection between the speed and the friction. For instance, with 1200lb. the highest speed gave the lowest friction, while the reverse was the case with the higher loads. Thus out of twenty experiments the results of sixteen agree with one another so nearly that the greatest variation from the mean is only 2·57 per cent.; an agreement so close that we think we may with confidence accept their testimony, and reject the remaining four. The diagram shown in Fig. 11 is plotted in this way, and may be considered to sum up generally the results of the experiments.

General Conclusions.—This kind of bearing is evidently very inferior to a cylindrical journal in its power of carrying weight; 3000lb. on 40 sq. in., or 75lb. per square inch, was as much as it would bear at the highest speed, though it carried 90lb. per square inch at the lowest. The co-efficient of friction is also much higher than for a cylindrical bearing, and the friction follows the law of the friction of solids much more nearly than that of liquids. All this is doubtless due to the much less perfect lubrication applicable to this form of bearing compared with a cylindrical one. The co-efficient of friction appears to be about the same with the same load at all speeds, or in other words, to be independent of the speed; but it seems to diminish somewhat as the load is increased, and may be stated approximately as 1-20th at 15lb. per square inch, diminishing to 1-30th at 75lb. per square inch.

SIEMENS-MARTIN STEEL.—The Altos Hornos Company, of Bilbao, Spain, have started a Siemens-Martin furnace of a daily output of 20 to 25 tons. The gas producers are of the Wilson type. No difficulty was experienced in starting the furnace as soon as it was ready, and the quality of the steel turned out is good.

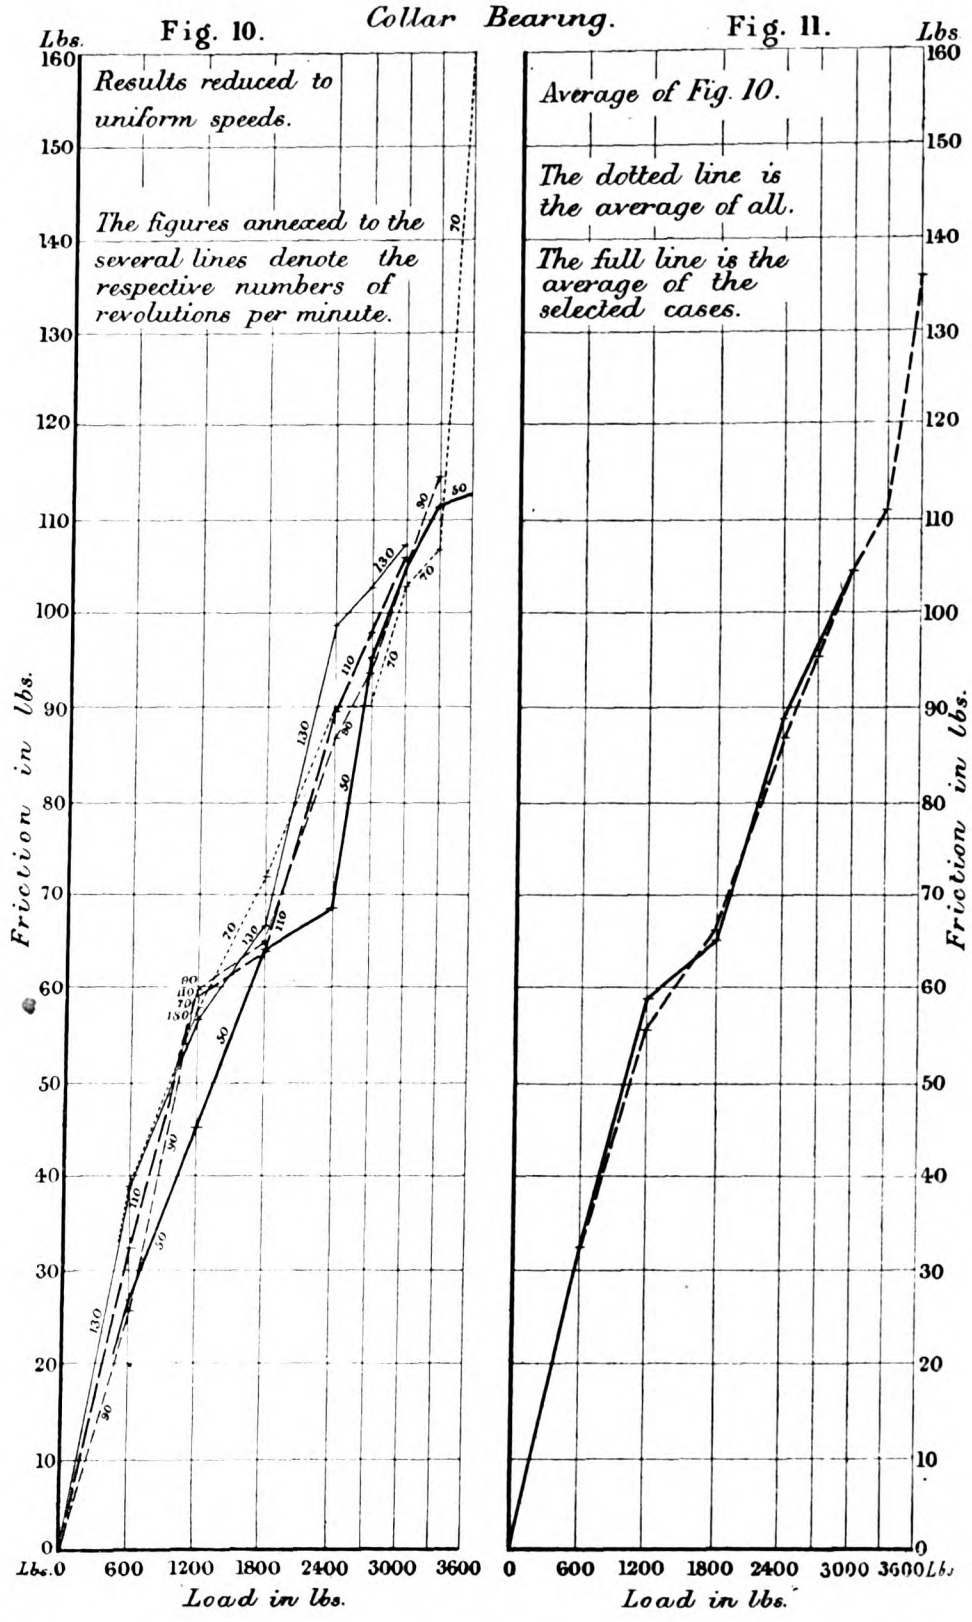
FARM HOMESTEADS OF ENGLAND.

By Professor T. J. Elliot.

In a former article on this subject, which appeared about two months ago (see page 250), I endeavoured to show the proportion of rent per acre per annum on a farm of 200 acres received by the landlord for his land, and what portion of the annual rent was swallowed up by the homestead. I will now try to show that the landlord gets more rent in comparison for his land per acre as the size of the farm increases. And if I succeed in doing so, the conclusion will force itself upon us—that it is for the landlord's interest to have his estate divided into as few farms as possible, in order to minimise the amount of original capital spent in the construction of their homesteads, and to increase his actual income from land. I will take a farm of 400 acres, which is double the area of the former. It will require a house, a set of farm buildings, and five cottages. Now, a farm of 400 acres does not require double the accommodation of one of 200 acres. The farm house will be the same as far as convenience and size are concerned. The buildings would be slightly larger, with additional yards for young stock, and sheds for waggons and implements, and five instead of three cottages. Thus the proportionate interest of the landlord's capital will be greater on the land and less on the buildings than in the former case. The 400 acre farm at 30s. per acre equals a rent of £600 per annum, allowing the same percentage for repairs as in the case of the 200 acre farm, and estimating the fee simple value to be equal to 28½ years' purchase.



We have £600 by 28·5 years' purchase equal to £17,100 fee simple value of farm, including buildings. A house, set of farm buildings, and five cottages will cost £1,960. Making roads, fencing, and water supply will amount to £500, making a total of £2,460. This amount deducted from the fee simple value of the holding gives £14,640, and represents the value of the land without buildings. Therefore, £14,640 divided by 33⅓ years' purchase (which is equivalent to the value of land without being chargeable with repairs to buildings, and also of Consols at par) equals £439. 4s. per annum, or 22s. per acre. The rent apportionated, therefore, stands thus: For land, 22s. per acre; for buildings, 8s.; making together the rent of the whole farm 30s. per acre. It will be remembered that the proportion on the 200 acre farm was 20s. and 8s. respectively for land and buildings; so that in this case the landlord obtains 2s. per acre increase of rent for his land, and could, therefore, afford to let the farm of 400 acres at 28s. per acre, when at the same time he must charge 30s. per acre for a farm of 200 acres if he is to receive a similar net rent per acre. Instances of this might be multiplied, but I think the two cases I have quoted will sufficiently prove the theory I have advanced. I will only in passing mention that in the case of a farm of 1000 acres being divided into two of 500 acres each, the landlord would have to obtain 10s. an acre increase on the two farms of 500 acres each, so as to be equal to the net rental value of one farm of 1000 acres. These are not mere estimates, but data derived from facts—and facts that every land owner ought to know. It follows, therefore, that it is to the interest of both landlord and tenant that our farms should not be sub-divided into small holdings, such as are advocated at the present day, for by so doing the landlord sacrifices income through expenditure on buildings, and the tenant pays a higher rent per acre.

Again, assuming the landlord to have borrowed the capital required for the erection of the homesteading, cottages, and for making improvements (such as road making, fencing, and water supply) from such a society as the General Land Drainage and Improvement Company, the two cases would stand thus: For the 200 acre farm £1,900 would have to be borrowed, for which the landlord would pay as rent charge £6. 3s. 11d. per annum for thirty-one years for every £100 borrowed (thus paying principal and interest in 31 years), or £117. 14s. 5d. on the total amount, which is equal to nearly 11s. 9d. per acre over the whole farm. In this case the landlord is the loser, as he only receives £100 rent for improvements which have cost him £117. 14s. 5d.—the borrowed capital. For the 400 acre farm it would be necessary to borrow £2,460, for which sum the same society would make a rent charge of £6. 0s. 4d. (see their scale of charges published in the Journal of the Transactions of the Royal Agricultural Society of England, 2nd series, Vol. IV., part I., 1868, page 135) for every £100 borrowed, or £147. 0s. 3d. on the total amount. Here the landlord would reap the benefit, seeing he obtains 8s. an acre, or £160 a year as rent for 7s. 4d. per acre or £147. 0s. 3d. borrowed. This forms another factor as far as the landlord is concerned in favour of large holdings *versus* small holdings. I will not venture to treat the subject from an agricultural point of view, because in doing so I should be going beyond the scope of the subjects generally dealt with in *Industries*. I will only add that agricultural facts would tend to strengthen the claims of the land owners.

Collar Bearing.

THE CLYDE TIMBER CARRYING TRADE.

That our legislators ought to carefully study the effects of their actions on trade has been most markedly shown by the effect of recent enactments on the Clyde timber carrying trade. From the time the Board of Trade officials adopted what many in the shipping community allege to have been harsh and extreme measures regarding the vessels engaged in this trade, it began to decline, and now the large fleet of timber carrying ships belonging to the Clyde, and sailing between that port and Quebec and the Gulf of St. Lawrence, has practically ceased to exist. Formerly, in the spring of each year, all was bustle about the quays and harbours with the fitting out of the fleets; but now all is changed. After the passing of the Plimsoll Act owners were so much worried and harassed that they disposed of their property, chiefly to Norwegians, who were able to carry on the trade as they pleased and without reference to any Acts of Parliament. While the British shipowner is restricted as to carrying deck loads, the foreigner can do as he likes, and under these circumstances he has entered into active competition with the British shipowner, and being able to sail his ships cheaper, both as to men and provisions, he is able to underbid the British owner in the market, with the result that freights from Quebec for the past two or three years have fallen so low as barely to give a sufficient return to cover expenses, and many wooden ships have been lying up on the Clyde "eating their heads off." Under these circumstances, companies and individuals holding such ships have resolved to get rid of them, and during the past few weeks a large amount of tonnage has changed hands at a low rate. We do not for a moment wish it to be supposed that we object to the Government interfering, when necessary, for the protection of sailors, but we wish most decidedly to protest against any arrangement which gives foreigners an advantage over British shipowners.

FOREIGN INDUSTRIES.

(From our own Correspondents.)

PARIS, 8TH MAY, 1888.

THE IRON MARKET.—The situation has altered but little in the course of the last week, and no other change than a steady development is to be looked for for some time to come. The principal factors are: The course of trade in crude iron in the Eastern departments, and the steadfastness of the manufacturers of the North in their resolve to maintain the prices of finished iron. The blast furnace owners are not likely to yield their position in the face of a brisk demand, rising prices for coke, and low stocks; and the makers of finished iron have shown themselves determined by combination to keep up the rates to a remunerative level. Hence the prospect is distinctly encouraging, and we may reasonably expect that the coming summer will be a period of constant, if slow, expansion. This view is now generally held by consumers, who are laying aside their reserve, and come into the market to buy more freely. The Paris merchants, recognising the necessities of the situation, have at length advanced their prices. One important house has issued a circular fixing the May price of bars at £6, and joists are advanced from £5. 10s. to £5. 12s. A demand has sprung up for old rails, which sell at 66s. to 68s. a ton. Reports received from the provinces all agree in describing business as fairly active and sound.

THE METAL MARKETS.—The event of the week is the collapse of the tin market. For several weeks past it had been plainly evident that the end of the unprecedented inflation was near. It has come, and the collapse has been as unprecedented in extent as the inflation. The record has been badly beaten this time, for never has the price of tin dropped £75 a ton in one week before. Probably we have before us now, as a consequence of the absurdly high rates which have prevailed of late, a long period of low prices. That copper is destined to follow the course of tin no one doubts, the only question being as to when the end will come. Apparently, this time is not at hand yet, for the Société des Métaux has, it is said, contracted with the Cape Copper Company for the whole of its output for three years at least at the price of £70 a ton. The market for copper remains unaltered, a feeble demand, with growing stocks, being its distinctive features. Lead has lost the rise of 8s. a ton gained last week. Spelter, too, is gradually receding. The Vieille-Montague Company has announced a reduction of 16s. per ton for zinc.

JAPAN AT THE PARIS EXHIBITION.—The Minister of Commerce and Industry has just received from the Japanese Government a detailed account of the exhibits by which Japanese industry will be represented at Paris next year. This collection of Japanese manufactures and works of art will be the most complete ever yet brought together.

RESISTANCE OF CONCRETE TO SHELL FIRE.—Experiments made at the camp at Châlons have shown that concrete affords great resistance to shell fire, even when the shells are charged with melenite or other powerful explosives. In consequence of these experiments the Minister of War is about to ask the Legislative Chamber to sanction a scheme for facing the casemated forts situated along the frontiers with cement concrete. The same shell fire which was directed against the concrete covered works proved destructive to iron clad turrets.

BERLIN, 7TH MAY, 1888.

THE COAL MARKET.—In my last letter I drew attention to the increasing imports of coal from Russian Poland, and to the depression in the price of the inferior kinds of Silesian coal caused thereby. This view is borne out by the results of recent tenders invited by the Breslau railway administration. Tenders were invited for 180,000 tons of large coal and 100,000 tons of nuts for locomotive purposes, and the quotations varied between 5s. 4½d. and 4s. 2½d. for large coal and 4s. 9d. and 4s. 2½d. for nuts. Borsig quoted for large coal 5s. 2½d., and Kattwitz 5s., whilst the Waldenburg mine made the lowest tender at 4s. 2½d. for both kinds of coal.

THE IRON MARKET.—The artificial inflation of prices still continues, and on the 20th of last month a further rise of 2s. per ton was resolved upon by the southern group of the German rolled iron syndicate. The base price of rolled iron in the South is now 122s. In Westphalia the struggle between blast furnace and rolling mill owners still continues, and the latter, with a view to emancipate themselves from the burden of high prices imposed by the crude iron syndicate, contemplate the erection of blast furnaces. Thus they regard with disfavour the extension of a policy to other trades which they were the first to inaugurate for rolled iron. Meanwhile, English pig is reaping the benefit of the situation. The condition of the wire trade, especially as regards rolled wire, is unsatisfactory. Inquiries are plentiful, but orders are scarce, and the export trade is almost at a standstill. What little demand there is for export can easily be met by the stocks in the hands of dealers. With the high prices of the raw material and the restrictions imposed by the syndicate, individual wire makers find it extremely difficult to compete against their English and Belgian rivals in neutral markets. At a recent sale of old rails by the Breslau railway administration the highest prices obtainable were 66s. 10d. at Breslau, 65s. 4d. at Oels, 69s. at Kreuzburg, and 75s. 6d. at Tarnowitz.

THE BASIC PROCESS IN SILESIA.—Two large companies, one a mining and metallurgical works, and the other a works for the supply of railway material, acquired in 1884 the sole right to use the Thomas-Gilchrist patent in Upper Silesia, for the consideration of £20,000. Although in Westphalia, and in other parts of Germany, the basic process has resulted in a great financial success, in Upper Silesia this has up to the present not been the case, and the dividends paid by both companies have been extremely meagre, notwithstanding the fact that their sole right to make basic steel has never been infringed.

THE MANUFACTURE OF TAPESTRY.—The state of trade throughout Germany, as regards the manufacture of tapestry, is at present very satisfactory. Cheap articles are mostly in demand, and those of better quality are not much asked for. Our exports to America, Spain, Belgium, Switzerland, and Italy have shown very favourable results; but those to Austria have, in consequence of the increased import duties, considerably declined.

RAILWAY CONTRACTS FOR SOUTH AMERICA.—The Chilian Government asked, a short time ago, for tenders for the construction of eleven lines of railway, amounting in the aggregate to some 700 miles. The time allowed for the receipt of tenders by the Minister of Public Works at Santiago expires on July 31st next. A great effort, to which the Government contributes a powerful support through the Consular agents, is being made to secure the larger part of these contracts for German firms. Letters from Santiago describe the situation as highly favourable to the success of this effort, English influence having been much weakened of late.

HOPS.—The province of Posen is, with the exception of Bavaria, the largest hop producing district in Germany, and the market there is at present very firm. The better qualities of hops are in good demand, but the prices are high in comparison with those quoted by Bavarian and Bohemian growers, and in consequence but few contracts are being made; only small parcels of medium qualities find a market, and no sales whatever are taking place in inferior qualities.

VIENNA, 7TH MAY, 1888.

THE IRON MARKET.—The situation of the iron market throughout the empire is favourable; and although the previous hopes for a brisk trade in building iron have not been fully realised as far as the Vienna market is concerned, the demand for girders and joists from the provinces is sufficiently great to counteract the weakening tendency at the capital. Even crude iron is beginning to revive, and considerable transactions have taken place during the past week. The firmness of the market has been strengthened by the shutting down of two blast furnaces for repairs at the Witkowitz works. These furnaces will not be put in blast again for two or three months. Business is also brisk in bar iron and sheets. The Alpine Mining Company, for instance, have booked sufficient orders for heavy plates to absorb their production for the next three months. In tinned and galvanised sheets business is also good. The Hungarian railways are placing, or have placed, orders for fifty locomotives, and the Austrian State railways are expected to shortly place orders for two hundred locomotives, and for a proportionate amount of other rolling stock. Locomotive and waggon works generally will thereby find remunerative employment for at least one year. The Vienna representative of Messrs. Nobel, of St. Petersburg, has just placed an order for ten petroleum tank waggons with the Austrian State railway works in Vienna. These waggons must be delivered by August next, and are intended for the carriage of petroleum in bulk from Fiume and Trieste to the interior.

SMALL ARMS.—The manufacture of small arms is an old established staple industry of Ferlach, in Carinthia, but like other trades in the duchy it has of late years considerably suffered. The local government, with a view to benefit this industry, have lately approached the Minister of Commerce with a request to assist the Ferlach manufacturers in forming new connections with export undertakings. The result of this step was that a special department has been assigned to the Ferlach manufacturers in the permanent sample exhibition of the Austrian Export Company. This has had the desired effect, as both the Export Company and the Transmarine Trading Company have placed considerable orders in Ferlach. The gun makers there have agreed to supply 1000 guns within six weeks. The weapons are intended for East Africa and for Singapore. Encouraged by this success the Ferlach gun smiths have formed themselves into a syndicate to watch over the interests of the trade.

ELECTRIC LIGHTING BY WATER POWER.—As already reported in one of my previous letters, plans were elaborated last year for a central electric light station for the town of Trient, the power to be supplied by the Fersina brook, a tributary of the Etsch. These plans have been adopted with certain modifications in detail, and work has since then steadily progressed. The waterfall is 2000 yards from the centre of the town, and 330ft. above it. The water for the turbines is carried by a tunnel 2000ft. long to an artificial reservoir of 900 tons capacity, and the supply is at the rate of 1600 gallons per minute. From the reservoir the water is carried by iron tubes of 35in. diam. to the turbine house, which is 2700ft. distant, whilst any surplus of water is drained off through another main 700ft. long back to the Fersina brook. The supply main for the turbines presented special difficulties on account of the many bends which were necessitated by the irregular condition of the ground, and only 70 per cent. of the whole line consists of straight pipes. The lower portions of the supply main have to stand a pressure of 120lb. per square inch; but they have been tested up to 375lb. The sluice valve at the lower end of the supply main is subjected to a total pressure of 164 tons. The total power available varies from 800 h.p. to 400 h.p., according to the season and climatic conditions. The power required for lighting purposes is estimated at 240 h.p., and the town authorities who are carrying out this work propose to utilise an average of 300 h.p. in the day time, and 150 h.p. in the evening for working motors. The tunnel and reservoir have cost 122,000fl., and the central station is estimated at 98,000fl., making a total of 220,000fl. The working expenses, including depreciation and interest, are estimated at 48,000fl., and to cover this expenditure the light would be supplied at the rate of 3·75 kreuzer, or say about ·7d. per 16 c.p. lamp hour; but when a greater number of lamps are taken up by the subscribers the town will be able to reduce the cost per lamp hour considerably below the figure quoted. The installation is to be in working order in November next.

BRUSSELS, 8TH MAY, 1888.

THE COAL MARKET.—The situation is maintained. Prices are 5s. 5d. to 8s. for unscreened coal, 8s. 5d. to 10s. for household coal, and 11s. 7d. for coke, at which rates contracts are being made for three to six months. In several mining districts the men are showing a disposition to strike for higher wages; but it is difficult for colliery owners to make a further advance in the rate of remuneration, as most of them have already given an increase of 10 per cent. The balance sheet of the Marchienne Colliery Company, which has a capital of £100,000, shows a profit of £10,344 on last year's working. The Carabinier Colliery at Châtelet, with a capital of £80,000, made a profit of £2,342. The Belgian producers of coke have difficulty in competing with French producers of the Nord in the Nancy district. In the Longwy districts, Belgian and French coke are on the same footing.

THE IRON MARKET.—There is little change in the iron market since my last letter. Manufacturers of finished iron who have no blast furnaces complain of the dearness of pig iron, which makes it impossible for them to compete in the home market with rivals who have furnaces of their own, or to obtain orders from abroad. It would be far more satisfactory if some understanding could be come to between rolling mill and blast furnace owners. Imports of foreign pig continue to increase largely. In the Charleroi district, English pig is sold at 42s. 5d., and is giving great satisfaction, as it contains less phosphorus than the native pig, and contains about ½ per cent. of manganese, which greatly improves its quality. The price at which it is sold is from 10d. to 1s. 8d. per ton less than that asked for pig made from Belgian ore. There is a good demand from Italy for girders, but at a reduction of 4s. per ton as compared with recent contracts. Steel is weak, and the tendency is in favour of buyers. Formidable foreign competition will have to be encountered at the next State railway contracts. The Société de Construction of Braine-le-Compte has obtained the concession for the Nauplie-Calamata railway in Greece.

GLASS WORKS.—The demand from England and America is good, and orders have been received from the United States which had been withheld during the discussion on the tariff, which has now been adjourned. Prices at New York are firm. The Société Anonyme de Verrerie, of Charleroi, made a profit of £3,546 in 1887, allowing for a dividend of 10 per cent.

TEXTILES.—Owing to the spinning mills having ample stocks, the sale of Russian hemp has been limited in extent. For home grown flax of good quality there is a considerable inquiry at firm prices. The demand for Russian flax is maintained.

THE EXHIBITION.—The nominal day for opening the Exhibition was Saturday last, when the gardens were opened to the public. The actual state of affairs is as follows: The buildings of the English section are ready, and exhibitors are installing their exhibits, under the personal superintendence of Mr. Lee Bapty; the machinery in motion here includes steam engines, spinning, weaving, aerated water, and brick making machinery; and among other industries represented are shipbuilding, cutlery, textile fabrics, china and glass, electricity, gas, and leather. In the German section many exhibitors have arrived, but their stands are not yet ready for them. The Commissary-General is M. Cornély, who is also Inspector-General of the Grand Concours, a combination of functions which is of doubtful expediency. The French section cannot be got ready for a month at least, this portion of the building not being roofed so far. The Belgian portion is also all behindhand; in the machinery gallery the floor is being laid down. The driving shaft for the machinery in motion has been fitted, and the counter shaft for the electric lighting is now being put up. One of the Naeyer boilers is erected, but none of the engines have arrived. There will be four large engines supplied by Carels, Hoyois, and the Phœnix Society for supplying the power for the electric lights; but only half of the available power will be utilised, owing to the adoption of a more restricted scale of electric lighting than was originally intended. No machines have been put up in the gallery, and the annexes are empty. As I have already announced, special efforts have been made to render the gardens attractive, and the electric lighting there

Digitized by Google

is very effective. Pieper, of Liège, supplies forty arc lamps of 10 ampères, fitted to posts 40ft. high, and the Brush Company will probably furnish a similar number of lamps. It is difficult to say at the present moment what measure of success the Exhibition is likely to achieve.

DÜSSELDORF, 7th May, 1888.

The Iron Market.—The German market for iron is now, as regards prices, largely dependent upon the state of trade in England. The difference has become such that English iron, both crude and finished, can be delivered duty paid, at a price which leaves a fair margin for profit, and consequently the fluctuations of the English markets, and the general level of prices, operate strongly here, and control, to a considerable extent, the situation. It is the most effectual check we have against a further advance. The trade in crude iron is fairly animated. Forge pig is somewhat dull, but there is increasing activity in other kinds. Life has been infused into the trade in spiegel pig, by orders received from the United States this week for 10,000 tons of the 20 per cent. quality. There are also prospects of other large orders from the same quarter. For basic steel pig there is a steadily growing demand, and prices have risen above the syndicate minimum. Nothing can now be bought for less than 46s. Foundry pig, too, is much sought after. In finished iron and steel the trade is on the whole healthy and strong. Bars are not so eagerly sought after as formerly, but there is a steady demand for home consumption sufficient to keep all the rolling mills working full time without accumulating stock. If only the foreign demand were moderately good, this branch of business would be very animated. Foreign orders for plates are fairly plentiful, and no order can now be accepted for delivery in less than six weeks; but, as I pointed out last week, the Siegen district is less favoured in this particular. The market is dull for sheets, which, however, are likely soon to come into better demand, for besides the fact that the building season is now again upon us, most of the manufacturers who held aloof from the syndicate have now joined that association, and steps have been taken to establish at once a common sales bureau. Founders' orders come to hand plentifully, and engineers are all busy. In nearly every direction the outlook is better than it was three weeks ago.

German Iron Abroad.—The German export trade in iron is constantly shrinking. This effect of the high prices, which are out of accord with those of rival producers, must soon make itself seriously felt. The total exports of all kinds amounted to 71,409 tons in March, against 77,183 tons in February and 78,422 tons in January. An analysis of these totals, however, shows that the falling off is of less importance than it appears at first sight to be; for we find a considerable increase in all manufactured goods, and in angles and plates. The shrinkage is in pig iron and scrap, and half wrought iron, bars, rails, and wire. The following figures show the exports in the first quarter of the current year, compared with those of the corresponding period of 1887: Pig iron, 36,634 (58,664) tons; scrap, 5460 (17,433) tons; half wrought iron, blooms, ingots, and puddle bars, 6558 (12,486) tons; finished iron, bars, angles, plates, &c., 56,258 (72,050) tons; wire, 47,111 (67,150) tons; rails, 18,188 (42,780) tons; other railway iron, 8286 (9985) tons; and manufactured goods other than machines, 48,519 (41,499) tons—total, 227,014 tons, against 323,047 tons last year, a decline of 29·7 per cent.

The Jute Industry.—The jute industry is suffering from over-production. The evil is now recognised, and measures are to be at once taken to remedy it. At a meeting of the Association of German Jute Manufacturers, held last month at Hamburg, to consider the situation, a resolution was agreed to unanimously, to restrict production by reducing the hours of labour to sixty a week. The quantity of raw jute imported in the first quarter of the current year amounted to 231,749cwt., against 227,552cwt. in the corresponding period of 1887, the exports being 5472cwt., against 3796cwt.; the quantity left for consumption in the country is 226,277cwt., against 223,756cwt. last year. The imports of jute yarns in the three months amounted to 8400cwt., against 9254cwt. in 1887, while the exports for the same periods show a small decline from 11,694cwt. in 1887 to 11,628cwt. in 1888.

LILLE, 8th May, 1888.

Textile Manufactures.—The markets for textile goods have developed no new feature since my last report. Generally there is less distrust of the future, leading to a better tone of affairs, which must be regarded as an improvement; but this amelioration is not yet sufficient to enable us to discern an increase of activity. During the past week an average amount of business has been transacted in linen goods. Most of the reports received from the Armentières district express disappointment over this year's spring trade, but this arises more from unrealised hopes of better times than from a falling off of business. In cotton goods there is not much doing. Wool is very firm in price, and the latest Roubaix quotations are a shade higher than those of a week ago. This firmness is, however, due not to a strong demand on the part of consumers, but to speculative buying to cover accounts opened for the fall some two months ago. For manufactured woollen goods there is a fairly active demand in some quarters, but nothing approaching to animation. We learn from Calais that the tulle trade of that locality has not realised the hopes formed concerning it. The season, which was expected to be one of considerable activity, has scarcely risen above dulness. American orders have been plentiful, but the home demand has shown a degree of languor for which it is not easy to account. From Lyons we learn that raw silk is being more actively dealt in. Prices are irregular, but there has been no decline.

Flax and Yarn Markets.—The flax market is lifeless. Only a few dealings of small importance have been recorded this week, and for these the prices are irregular. There is not much home grown flax on offer, while the demand is good. All accounts agree in describing the new crop as making satisfactory progress. The market for yarns has not materially changed since last week; the distinctive features are the same, viz., a brisk demand for the finer numbers, and dulness with prices in favour of buyers for the heavier sorts.

Raw Textile Materials.—The Customs returns show some important changes in the trade in raw textile materials in the first quarter of the current year, relatively to the corresponding period of 1887. Thus, among the imports, the declared value of flax is £921,520 (£823,200); that of jute, £138,520 (£154,080); that of cotton, £1,959,200 (£3,971,760); and that of wool, £4,021,240 (£3,130,080). It will be observed that there is a heavy falling off in cotton, and a large increase in wool. The values of the exports in the same period are: For scutched flax and tows, £110,760 (£118,320); for cotton, £363,760 (£398,760); and for wool, £1,125,040 (£888,520).

The Iron Market.—The past week has brought nothing new to the iron market of this locality, and this statement is, perhaps, the best that could be made concerning the trade in iron, which for several weeks past has been sufficiently active to keep all manufacturers fully employed. The market seems at last to have settled down to a steady course of business, with prices at a fairly remunerative level. From time to time fresh blast furnaces are brought into operation, for the consumption of pig iron is somewhat in excess of production. A serious accident occurred at Hautmont last week, on the occasion of re-lighting two blast furnaces. In consequence, as it seems, of the air not having been completely driven out of the gas pipes, a terrific explosion occurred, seriously injuring twelve men—three, it is feared, mortally—and doing great damage to property.

WINTERTHUR, 7th May, 1888.

The Paris Exhibition.—Up to the present 732 Swiss firms have notified their intention to be represented at next year's Paris Exhibition, as compared with 962 firms which participated at the Exhibition of 1878. They will occupy 3800 square metres of floor space, and 1400 square metres of wall space. The exhibits will represent a value of £108,000. Engineering will be the industry best represented, there being 136 exhibitors in this section, occupying 3000 square metres.

Our Postal Service.—The returns of the Post Office are, in a certain measure, an indication of the industrial activity of a country, and in this respect it may be interesting to note the enormous increase which has taken place in the number of letters and other articles forwarded through the post since the time when Switzerland began to be an industrial nation. In 1850 the Federal Post transmitted 1,290,716 parcels, 10,601,325 book packages, and 15,106,117 letters. Last year the figures were 11,451,456 parcels, 64,373,458 book packages, and 132,313,967 letters. The money orders transmitted amounted to 309,063,981 francs.

MADRID, 7th May, 1888.

Submarine Torpedo Boat.—Major Cabanyes, of the Artillery Corps, has been busy for some time past, with the assistance of the War Department, in making preparations for the construction of a submarine torpedo boat. The motive power will be electricity. The boat will carry 160 large accumulators, and a 60 h.p. Oerlikon electric motor. The accumulators are claimed to surpass all others now existing for storage capacity and duration, but the materials employed are kept strictly secret. So far, Major Cabanyes has taken out no patent for the accumulators, and seems to be inclined to make their construction a War Office secret The accumulators have been tested for some months, and I have been allowed to examine the test book, which proves their storage capacity and rate of discharge to be remarkably high.

Railways.—For many years two powerful financial syndicates—one under the direction of Messrs. Rothschild, and the other under Messrs. Periere—have had an arrangement whereby the former were not to apply for any railway concessions north of Madrid, and the latter gave a similar undertaking with respect to lines south of Madrid. The result has been that fully one-half of the railways in this country are in the hands of companies controlled by these financiers. Their returns have been fairly satisfactory. Baron Alphonse de Rothschild, accompanied by M. Leon Say, has been in Madrid, and this visit has given rise to a rumour that it is intended to amalgamate the syndicates into one powerful company.

The Huelva Fumes.—In view of the possibility of the order to stop the open air roasting of pyrites at Huelva being enforced, one of the companies has discharged three hundred workmen, who are now in great distress. Some thousands will be thrown out of work if the order is carried out.

NEW YORK, 28th April, 1888.

The Iron and Steel Markets.—The condition of the iron trade is as unsatisfactory as ever; so far there is no indication of a change, and the feeling of depression is almost as great as during a period of absolute dulness. The decrease in consumption during the first quarter of 1888 has been over a quarter of a million tons, as compared with the corresponding period of 1887, while there are indications that the second quarter will show a still greater falling off. The decrease in the volume of business is not by any means the worst feature, as the falling off in price leaves producers with little or no margin of profit, while their fixed charges are practically the same. The volume of business is large compared with almost any year before 1886, but the increase of capacity leaves the average of employment very little better than during periods of greater depression, so that the comparatively large business is of but little benefit to individual operators. The enormous consumption of 1886 and 1887 was based largely on railway building, including equipment of all kinds, rails, bridges, cars, locomotives, &c. The demand for rails is not likely to be over two-thirds of that of last year; and while there is not yet much falling off in the other specialties named, business comes in slowly, indicating increasing dulness. Another serious loss to the iron trade is the falling off in the demand for pipes for natural gas, &c. Last year, at this time, almost every mill could get large orders at a fair margin of profit, while to-day an order for 500 tons is rare. Some heavy transactions have been closed during the week in pig iron, but taking the market as a whole there has been no material change since last week. Buyers are not yet satisfied that bottom prices have been reached, and are therefore only buying what is needed for actual use, unless special rates are offered, which has been done in several cases. The offerings of good brands are unusually light for the season, which keeps prices steady. Producers are directing their efforts towards securing lower freights and cheaper fuel, being pretty well convinced that to lower cost is the only means by which they can hope to retain their trade. Standard No. 1 foundry sells at $20 to $21 per ton, with Southern irons from 50 cents to $1 less per ton. There is no improvement in manufactured iron. The only fairly encouraging outlook is in shaped iron, and even that is hardly on a good basis. The steel rail market is very quiet, but there is no change in prices; and from present appearances it is not likely that there will be any for some time. The mills are fairly busy, with sufficient orders on hand to last until midsummer.

The Coal Market.—The anthracite coal trade is inactive, and buyers only order for present needs. There is a large production, but enough is being absorbed by Western trade to keep prices comparatively steady. There does not seem to be any likelihood of furnace coal becoming cheaper, and thereby relieving the iron trade.

The Metal Market.—The copper market is easier, with slightly increased sales. The Calumet and Hecla Mine has not been opened yet. The tin plate trade is dull; stocks are still small. The lead market has been steady, at 4·70 cents per lb. Consumers have bought very lightly, while about 1000 tons have been sold to speculators.

Exhibition at Cincinnati.—Manufacturers and merchants of our Western cities are actively preparing for the Cincinnati Exhibition, which will open on July 4th and close on October 27th. Over £200,000 has been subscribed as a guarantee fund. Eleven States are officially connected with its management, and it will be probably the best exhibition held in this country since 1876. The buildings are now well advanced. The main building, which will be in the shape of a cross, will be 600ft. by 400ft., and the park building, covering an artificial lake, will be 600ft. by 110ft. The power hall will be 1247ft. by 112ft., and will have the Miami and Erie Canal running through its centre. The total available floor space will be 23 acres.

PHILADELPHIA, 28th April, 1888.

Liquid Fuel.—A number of tests has been made at the Salem (Mass.) pumping station to determine the relative commercial advantages of coal and oil as fuel. The station pumps 3,250,000 gallons per twelve hours. The cost of coal for five hours was $4·69 and for oil $3·35, and in addition to the economy in first cost the oil has the advantage of cleanliness, ease of regulation, while maintaining a more uniform steam pressure. Negotiations are progressing favourably for the introduction of oil into several of the large manufacturing concerns in this city. In many of the larger works in the country it has already been introduced with favourable results. The Union Steel Works at Chicago have converted their furnaces at a cost of £20,000, and now consume 1200 barrels of oil per day. At these works the system has also proved very successful.

Electric Transmission of Energy.—A large undertaking in the transmission of power is now being carried out by the Sprague Electric Railway and Motor Company for the Big Bend Tunnel and Mining Company. The latter owns fifteen miles of the bed of the Feather river. As they intend to carry on their mining operations directly in the bed of the river, they have built a tunnel 2½ miles long across the horseshoe bend, diverting the entire stream, and leaving the bed dry. To obtain the necessary power to work their machinery, they have decided to locate their generating dynamos below the exit of the tunnel, thus giving the turbines 300ft. head of water to work under, and the current from the dynamos will transmit power to fourteen different stations around the old bed of the river.

TELEGRAPHIC COMMUNICATION BETWEEN CHINA AND EUROPE.

THE United States Minister to China, in a report to his Government, describes a convention recently concluded at Cheefoo between the representatives of the two telegraph companies having cables landed in China and the Chinese telegraph administration, which has created considerable alarm among the foreign mercantile communities in China, although the convention still requires to be ratified by the Chinese Government. According to it, the Great Northern Telegraph Company of Copenhagen, and the Eastern Telegraph Company of London, have divided the territory in China. The lines of the former run north through Japan to Vladivostock and Eastern Siberia, while the English company's lines run south through Singapore and India. The messages to and from the interior are sent over the Chinese lines, and under arrangements hitherto existing the Chinese telegraph administration received 50 cents per word for messages sent abroad from the interior, while under the arrangement proposed by the convention the Chinese would receive 70 cents. The convention sets forth that the Chinese telegraph administration intends to connect its system with the telegraph lines of adjacent countries, that the two companies also have this connection, and that it is desirable "to avoid competition," and the rates are fixed to the mutual advantage of the Chinese telegraph administration and of the cable companies, and it is stipulated that these shall not be changed, except by mutual consent. The parties to the agreement shall do all in their power to prevent the transmission of messages by any person or corporation at rates lower than those fixed, and neither party shall be interested in any other company by sea or land, to the detriment of either of the others. The cables shall not be extended to any place in China or Corea without the consent of the Chinese administration, but existing land rights shall be preserved. The agreement is to take effect from the day that the administration shall connect their lines with the telegraph lines of any adjacent country in telegraphic communication with Europe, and shall be in force until May, 1903. The American Minister says the substance of this agreement is that China will receive about $150,000 per annum more than she gets now, while the advantage to the cable companies is that for sixteen years they will have no serious competition; for, although any one may lay cables to China from any part of the world, the Chinese are able to prevent any enterprise of this nature by refusing to allow them to be landed on their territory. The rates fixed in the agreement contain a slight concession to the general public, there being a reduction of 50 cents per word. But foreign merchants demand that the price be fixed at $1 per word. The companies, however, take the ground that no man telegraphs except when compelled to do so, and that their business would not be increased if the rate were reduced to $1. This, in our opinion, is short sighted policy, and contrary to the teachings of all experience in such matters.

IMPROVED PULLEY MOULDING MACHINE.

THE accompanying illustrations show an improved moulding machine for pulleys or similar objects, introduced by Messrs. J. G. Neville & Co., engineers, Liverpool. Figs. 1, 2, and 3 show the method for moulding pulleys like that illustrated in Fig. 9, while Figs. 4, 5, 6, and 7 show the way in which pulleys of the shape shown in Fig. 8 are moulded. A frame A A (Fig. 1) supports on a number of arms the ring B, which carries a ring C C, the inner diameter of which equals the outer diameter of the pulley pattern. This ring is interchangeable, so as to allow pulleys of different diameter to be moulded. To the frame A A is attached a circular plate D D, the centre of which exactly coincides with the centre of the ring C C, the diameter of D being smaller than the inner diameter of C, thus leaving a circular space just wide enough to let the pattern E of the pulley rim pass. The pattern E is secured to a cross-shaped plate F, which is moved up or down by means of a screw K, actuated by bevel gearing and a hand wheel. E is made of cast iron, turned, and tapers towards the bottom, so as to make the rim of the pulley thicker in the middle than at both sides. When moulding, E is made to protrude above C and D, exactly half the width of the rim of the pulley to be cast. As will be seen, the thickness of the middle part of the rim is less in narrow pulleys than in wide ones, which corresponds with actual practice. For moulding the arms of the pulley, a pattern L is used, which has half the thickness of the finished arms, and is secured to D by screws. To this pattern the boss G is attached. The moulding is done in the following manner: A flask H is put on to the machine, and fixed in a suitable position by means of the pins I I. The flask is then filled with sand, which is rammed round the pattern in the ordinary manner. After this has been accomplished, the plate F and with it the pattern E is lowered by means of the screw K, as shown in Fig. 3, and the flask lifted off the machine. A second flask is put in exactly the same position as the first flask, by means of the pins I I, and E raised to the same height above D as before; then flask two is treated in the same manner as flask one, and by connecting the two flasks a complete mould of the pulley is made. By this method, pulleys with straight rims are obtained; but in many cases it is desirable to give the pulley rim a convex shape, and a device for accomplishing this is shown in Fig 3. The pattern is first moulded in the manner already described, with the exception that the sand is only filled into the space between the flask and the outside of E, which is then withdrawn, and a pin M secured in the centre of D, round which the template N swings. By this means the sand is cut away to the required curve. After removing the template N the pattern E is lifted up again, and the mould finished in

Digitized by Google

the way already described. Figs. 4, 5, 6, and 7 illustrate the method of moulding a pulley with two sets of arms, as shown in Fig. 8. The machine is the same as that shown in Figs. 1, 2, and 3; but three flasks, H_1, H_2, and H_3, instead of two are used in this method. First, the flask H_1 is put on the machine, and E raised the distance *a* (Fig. 8) above D, the arm pattern and the boss G is placed into position, the mould finished, and the flask removed from the machine. Now the flask H_2 is put into position on the machine, and the pattern E moved upwards until it protrudes the distance $a + b$ (Fig. 8) above D. The sand is then rammed in between the flask H_2 and the outside of E to the top of the flask. Before filling the inner part of E, triangular iron plates M (Fig. 7) are put between each two arms of the pattern and connected to bolts N. These plates carry the sand O between the arms L and P (Fig. 6), and are secured by means of the bolts N and nuts and washers to the upper flask H_3. The sand inside E is only rammed to a height equalling the distance *b* (Fig. 8). Then H_3 is put in position, and a whole arm pattern P is put into the place of the half pattern used for ramming O. The flask H_3 is then filled with sand and rammed round the pattern. After lifting H_3 the pattern P is removed and the flasks put together in the manner shown in Fig. 6, which represents the finished mould. The advantages claimed for this machine are, that an apprentice can do the work of two skilled moulders, and that the castings are cleaner and better than those cast in hand made moulds. The machine is made in two sizes; No. 1 for moulding pulleys from 8in. to 24in. diam., and 3in. to 16in. wide; and No. 2 for pulleys from 16in. to 40in. diam., and up to 20in. wide.

Notices of Meetings.

THIS WEEK.

SOCIETY OF ARTS.—Friday, 11th, and Saturday, 12th May, at 2 p.m. and 11 a.m. respectively. Conference on Canals and Inland Navigation.

ROYAL UNITED SERVICE INSTITUTION.—Friday, 11th May, 3 p.m. Paper to be read on "The Formation of Volunteer Field Batteries for Home Defence," by Captain F. G. Stone.

PHYSICAL SOCIETY.—Saturday, 12th May, 3 p.m. Papers to be read: "Note on the Condition of Self Excitement in a Dynamo Machine," and "Note on the Conditions of Self Regulation in a Constant Potential Dynamo Machine," by Professor S. P. Thompson; "Note on the Electrical Action of Light," by Professor W. E. Ayrton; "The Theory and Practice of Applying the Dynamometer to the Investigation of Transformers," by Mr. T. H. Blakesley; and "Measuring the Electromotive Force of Dynamos and Motors," by Professors Ayrton and Perry.

NEXT WEEK.

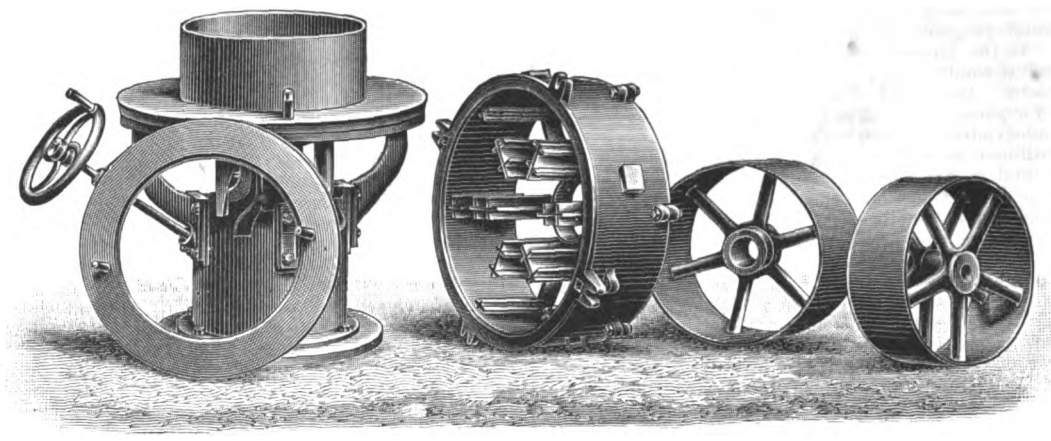
SOCIETY OF ARTS.—Monday, 14th May, 8 p.m. Cantor lecture on "Decoration," by Mr. G. Aitchison, A.R.A.—Tuesday, 15th May, 8 p.m. Foreign and Colonial Section. Paper to be read on "Emigration," by Mr. James Rankin, M.P. —Wednesday, 16th May, 8 p.m. Ordinary meeting. Paper to be read on "Electric Lighting from Central Stations," by Mr. R. E. B. Crompton.

INSTITUTION OF CIVIL ENGINEERS.—Tuesday, 15th May, 8 p.m. Papers to be discussed: "The Tay Viaduct, Dundee," by Mr. Peter Crawford Barlow, B.A., M.Inst.C.E.; "The Construction of the Tay Viaduct, Dundee," by Mr. W. Inglis, Assoc.M.Inst.C.E.

ROYAL INSTITUTION OF GREAT BRITAIN.—Tuesday, 15th May, 3 p.m. Lecture on "The Plant in the War of Nature," by Mr. W. Gardiner.—Thursday, 17th May. Lecture on "The Chemical Arts," by Professor Dewar.—Friday, 18th May, 9 p.m. Lecture in French on "La Reproduction Artificielle des Roches Volcaniques," by M. Alphonse Renard.

ROYAL STATISTICAL SOCIETY.—Tuesday, 15th May, 7-45 p.m. Paper to be read on "Condition and Occupations of the People of East London and Hackney, 1887," by Mr. Charles Booth.

ROYAL METEOROLOGICAL SOCIETY.—Wednesday, 16th May, 7 p.m. Papers to be read: "Report of the Wind Force Committee on Experiments with Anemometers conducted at Hersham," drawn up by G. M. Whipple, B.Sc., F.R.Met.Soc., and W. H. Dines, B.A., F.R.Met.Soc.; and on "The Measurement of the Increase of Humidity in Rooms by the Emission of Steam from the so-called Bronchitis Kettle," by William Marcet, M.D., F.R.S., President.



ARCHITECTURAL ASSOCIATION.—Friday, 18th May, 7-30 p.m. Ordinary meeting. Election of officers. Paper to be read by Mr. A. H. Hart.

ROYAL UNITED SERVICE INSTITUTION.—Friday, 18th May, 3 p.m. Paper to be read on "The Naval Defence of the United Kingdom," by Rear-Admiral P. H. Colomb.

GREAT NORTHERN TELEGRAPH COMPANY.—Traffic Returns: Receipts in April, 1888, £21,400; 1st January to 30th April, 1888, £85,200; corresponding months, 1887, £81,520; corresponding months, 1886, £78,480.

WE have been requested to state that Messrs. E. H. Birley and Co. have commenced business as consulting engineers at Queen's Chambers, 80, Deansgate, Manchester. Mr. E. H. Birley was recently a member of the firm of Messrs. C. S. Madan and Co., of St. Ann's Square, Manchester.

IMPROVED PULLEY MOULDING MACHINE.

PRICES CURRENT, 10TH MAY.

Quotations at per ton, unless otherwise specified.

Messrs. Carrick & Brockbank, Manchester, report as follows:—

COPPER.—The copper market remains in much the same condition as reported last week. The spot price is maintained at about £80 per ton by heavy purchases for the syndicate; whilst forward parcels are offered at about £5 per ton less. This is the speculative aspect of the market, the consumers meanwhile looking on and buying as little raw copper as possible, until it can be seen whether the French syndicate can really carry out their undertaking. The fall in tin has led to the forward selling of copper at lower prices, and for the moment it has materially affected the position of copper. Stocks of copper continue to increase rapidly. According to published statistics, the total supplies for the first four months of the current year are 39,308 tons, and for the same period last year 22,341 tons; and deliveries to the trade, 17,056 tons and 28,578 tons respectively; thus showing in the estimated visible supply an increase of 22,252 tons during the past four months. Manufactured is very quiet.

TIN.—Quotations for Straits are again lower. To-day, for spot and short prompt £80 per ton, with a tendency to stiffen again for the moment. The total visible supply, Europe and America, for the twelve months ending April 30th, is estimated as 44,588 tons, and the consumption as 29,773 tons, thus showing an increase during the same period of 14,815 tons.

LEAD is again lower, Spanish being quoted £13 to £13. 2s. 6d. per ton, with a slow demand.

SPELTER.—Quotations are lower, £17. 5s. to £17. 10s. for warrants, with a drooping market.

CARRON PIG IRON—BRAND "CARRON."

HOME INDUSTRIES.

MANCHESTER, 10th May, 1888.

The Cotton Trade.—For some time the Liverpool traders have been raising the cotton prices by means of the usual prognostications about the exhaustion of the crop. As the Lancashire spinners have plenty of cotton to hand, it would seem to be their policy to buy sparingly at present. As a result of higher cotton prices, the quotations for yarns have materially strengthened, and spinners are endeavouring to restore their profits. This is somewhat difficult to do, on account of the fact that manufacturers find it impossible to obtain any advance on the recent prices for cloth, and they are indisposed to pay more for yarn. In the cloth trade there is some difficulty in obtaining adequate prices, more especially in the staple goods for the Eastern markets. Manufacturers all complain that they have some trouble to maintain their quotations, owing to the very low offers which are being made from India. The low price of silver is detrimental to the merchant and manufacturer, and although there is a great number of orders being offered, the rates at which they are tendered renders their acceptance almost impossible. Another source of weakness in the cloth trade is the continual starting of new looms. The extensions which have recently taken place have not yet ceased. It may be explained that the practice is for sheds to be built, engined, and geared by the proprietors, and then let off in sections sufficient for twenty looms and upwards to tenants whose rent includes power. In some cases the looms are also sold on the hire system, so that it is comparatively easy for an operative who has saved a little money to commence business. In many cases he is able to find many of the workpeople in his own family, and these small ventures are thus worked very economically. The system of yarn sale permits his obtaining the necessary material readily, and it is not difficult for him to find customers for his cloth on a cash basis. Briefly stated, the general effect of this arrangement is that a large number of small firms have been added to the list of those already existing, and the producing power has thus been largely increased.

Wages Troubles.—By a large majority the operative spinners of the Oldham district have resolved upon striking on the 19th inst. if an advance of wages to the extent of 5 per cent. is not granted, and their example will probably be followed by the card room hands. In a minor branch of the business at Blackburn a similar course is threatened, the loomers and drawers having decided to strike for a uniform list of wages. Although the number of men directly affected by this last threat is not very large, yet the result of their action will be indirectly felt by a great number of operatives. In the engineering trades there is still a strike of moulders going on, and no signs of settlement are visible. This trouble only affects the Manchester and Oldham districts, but it is causing some disturbance of business in those two localities. There is also a strike of grinders and glazers in the machinery trade, and the trouble created by their action is altogether out of proportion to the number of men employed.

The Manchester Ship Canal.—The works in connection with this undertaking are making very rapid and continuous progress; and in some sections, notably those at Eastham, Weston Point, and Moore they are beginning to assume the appearance of a canal. It is intended to apply to Parliament to suspend the standing orders to permit of the passage of a Bill which will allow of an alteration of the docks. This involves amongst other things a re-adjustment of the boundary of Salford, the construction of an additional bridge across the river, and the raising of the level of much of the low lying land which adjoins the canal. The consent of the local bodies concerned has been obtained, and it is hardly likely that there will be any serious objection.

LONDON, 10th May, 1888.

The Money Market.—The money market has been stiffened by the resolution of the Bank directors a week ago not to raise the official rate of discount, although heavy withdrawals of gold had been made, and although new loan issues were creating a considerable demand for accommodation. A large proportion of the gold went to Scotland. In consequence of the non-alteration of the Bank rate, the outside rates soon approached the official minimum, and loans were even taken from the Bank rather than from Lombard-street. The Stock Exchange settlement has helped to maintain the rates at the higher figures. Values on the Stock Exchange have not recovered the ascending tendency which was checked ten days ago, although the feeling is more buoyant. Home railway stocks have been very dull; but the improved weather, together with the more favourable trade returns, should result in a rise in their price. Government stocks lack life, as also do foreign stocks; but the American market has an unmistakeably better tendency. Mines are not in great favour.

Companies.—The following new companies have been registered since our last report: Buckley & Bent, Limited, with a capital of £30,000, to carry on the business of cotton spinners; the Carenero Railway and Navigation Company, Limited (Venezuela), with a capital of £650,000; Courage and Co., Limited, with a capital of £1,500,000, to acquire the business carried on at the Anchor Brewery, Horsleydown, Southwark; the Bournemouth Electricity Company, Limited, with a capital of £50,000; Robinson, Skinner, and Co., with a capital of £30,000, to carry on business as glass manufacturers at Warrington, London, and elsewhere; Cheltenham Original Brewery Company, Limited, with a capital of £120,000, to carry on the business of Mr. J. T. Agg-Gardner, M.P.; Bindley & Co., Limited (Burton-on-Trent), with a capital of £170,000, to carry on the business of brewers; the Avenue Mills Company, Limited, with a capital of £16,000, to purchase a weaving shed and buildings at Chorley, Lancashire; the Gwendraeth Tin Plate Company, Limited, with a capital of £50,000; Contractors, Terra-Cotta, and Commercial Agents, Limited, with a capital of £250,000; the Compressed Air Carpet Beating Company, Limited, with a capital of £50,000; the Liverpool Pure Ice Company, Limited, with a capital of £20,000; Patent Cement Company of England, Limited, with a capital of £300,000; the Writtle Brewery Company, Limited, with a capital of £100,000; the Dordogne Mineral and Smelting Company, Limited (France), with a capital of £100,000; Great Northern Salt and Chemical Works, Limited, with a capital of £200,000, to raise and manufacture salt, and to manufacture soda and other chemicals; Morewood's Lion Galvanising Company, Limited, with a capital of £50,000; the Hope Iron, Steel, and Tin Plate Company, Limited, with a capital of £25,000; the Spanish Railways Trust and Investment Company, Limited, with a capital of £2,000,000; Hants and Wilts Brewery, Limited, with a capital of £45,000; the Woolwich Ship and Engine Repairing Company, Limited, with a capital of £20,000; Manchester Zinc and Ammonia Company, Limited, with a capital of £25,000; Leeds Hemp Spinning Company, Limited, with a capital of £10,000, to purchase the business of William Smith & Co., Crown Point Flax Mills, Leeds; the Farnham Brewery Company, Limited, with a capital of £30,000; the Houdol Gold Mining Company, Limited (Transylvania), with a capital of £50,000; Gold Mining Association of France, Limited, with a capital of £1,500,000; the Continental Gold Mines Company, Limited, with a capital of £200,000; the Bechuanaland Exploration Company, Limited, with a capital of £150,000; Notre Dame des Victoires (Transvaal) Gold Mining Company, Limited, with a capital of £250,000; the New River Consolidated Gold Mines, Limited (California), with a capital of £150,000; the Gold Estates (Transvaal) Company, Limited, with a capital of £130,000; Standard Mining Company, Limited, with a capital of £250,000, to acquire mines in Great Britain and Ireland, or elsewhere; Crown Lands (North Wales) Gold Exploration Company, Limited, with a capital of £80,000; the Douglas Witwatersrand Company, Limited, with a capital of £250,000, to acquire mining claims in the Transvaal; Tapia Iron Ore Mining Company, Limited (Spain), with a capital of £15,000; Hayford Brothers & Co., Limited, with a capital of £70,000, to purchase mines on the Gold Coast; the Bebside Coal Company, Limited, with a capital of £104,400; the Jone (Nevada) Silver Mines, Limited, with a capital of £120,000; the Colossus Silver Lead Ore Company, Limited (Wales), with a capital of £30,000; the Mid-Cumberland Silver Lead and Blende Mines, Limited, with a capital of £20,000.

A Union of Telephone Companies.—A very important company has been registered in connection with the proposed federation of the telephone companies, under the title of the United Kingdom Telephone Union, Limited, with a capital of £10,000,000. The promoters had already registered a company a week earlier, with the same amount of capital, the first subscribers being seven in number, as legally required; but this appears to have merely been a matter of formality. The first subscribers to the second company include the chairman, the deputy chairman, and five directors of the Union Telephone Company, Limited, the chairmen of the Lancashire and Cheshire Telephone Exchange Company, Limited, the National Telephone Company, Limited, the Telephone Company of Ireland, Limited, the South of England Telephone Company, Limited, the Western Counties and South Wales Telephone Company, Limited, and the Northern District Telephone Company.

Textiles.—There has been but little change on the whole in the prices paid on the second series of sales of Colonial wool; but there has been rather more competition, and in some instances rates are firmer. The series closed on Saturday last, and it is estimated that over half of the quantity sold has been taken for export. Messrs. Balme state that the consumption is large, and in spite of narrow trade margins of profit and unfavourable external influences, the requirements of machinery are on a scale which hardly admit the expectation of any retrograde movement in the near future, especially as, owing to the rapidity with which the Australasian clip has been despatched this season to the European markets, the subsequent auctions of the year promise to be more lightly loaded with arrivals than the present and the preceding series. The third series of Colonial wool sales will commence on the 19th of June with a limit of 350,000 bales, and the fourth and fifth series on the 18th of September and 27th of November respectively, without limitation as to quantity. Hardly any business is being done in Baltic hemp, either for spot parcels or for arrival. Prices for Manilla hemp for arrival show some weakness.

Board of Trade Returns.—The value of our exports during April amounted to £17,735,474, as compared with £16,411,662 in the corresponding month of 1887, being an increase of rather over 8 per cent. Cotton piece goods show a decrease in quantity of 5 per cent. and in value of 4 per cent., but in all the other principal articles of export business has improved. The quantity of iron and steel exported has increased by nearly 2 per cent. and the value by nearly 10 per cent. In hardware and cutlery the increase in value amounts to 12 per cent., and in machinery and mill work to 19 per cent., this being mainly due to larger shipments to India. The value of the total imports amounted to £32,098,693, as compared with £31,149,925 in the same month of last year, being an increase of 3 per cent. The imports of copper ore and regulus show an increase in quantity of 115 per cent. and in value of 302 per cent.

Railways.—The gross receipts of the twenty-three principal railways in the United Kingdom for the week ending 29th April amounted to £1,219,781 on 15,850½ miles, as compared with £1,218,442 in the corresponding period of 1887, when the mileage was 15,724 miles. An increase is thus shown in the mileage of 126½ miles or 0·8 per cent., and in the receipts of £1,339 or 0·1 per cent.

Colonial Contracts.—Messrs. Dick, Kerr, & Co. have secured a further large contract for rails and other constructive materials in connection with the Melbourne Cable Tramways.

GLASGOW, 10th May, 1888.

General Business.—The occurrence on two consecutive days of the Scotch Bank holiday and of the public holiday for the opening of the Exhibition, seriously interfered with business during the early part of the week. The Stock Exchange did not hold a holiday on Monday, but this was due to the incidence of the settlement rather than to the pressure of business. The Scotch pig iron shipments for last week showed a slight increase both coastwise and abroad. Freights are still fairly steady, though there is comparatively little being done.

The Boundary Commission.—The Boundary Commission has published its report, which in effect proposes to annex to Glasgow all the surrounding burghs with certain exceptions. All the districts which can properly be called urban have been included in the proposed new city boundary. The scheme of the Corporation of Glasgow has been practically adopted by the Commission. Among other changes proposed in the report of the Commissioners is the abolition of the differential water rate and a rearrangement of districts, so that the thinly populated better class neighbourhoods should be conjoined with more densely populated districts for rating and other purposes.

Glasgow Subway Scheme.—Evidence has been given during the week before the Lords' Committee. Mr. Deas, engineer to the Clyde Trust, in his examination, said that to deepen the river from Glasgow to Greenock would cost upwards of three-quarters of a million. The London and Glasgow Shipbuilding and Engineering Company claim that the construction of the subway would damage their launching ways, and the proprietors of a hotel near the proposed terminus demand that their property should be purchased outright. The Caledonian Railway Company also insisted through the evidence of their engineer, Mr. Cunningham, C.E., that the construction of the subway would affect the foundations of the joint line station in Eglinton-street, under which the subway must pass. The counsel, in answer to the chairman, intimated that there was a likelihood of both the Subway Bill and the Central Railway Bill being disposed of before the Whitsuntide recess.

(From our own Correspondents.)

LIVERPOOL, 9th May, 1888.

The Timber Trade.—The demand for yellow pine during the last month has been very small, and the stock of both waney and square pine is unusually light. The stock of red pine is also very low, and there has been practically no consumption. The supply of pitch pine has been in excess of the demand; four cargoes, principally of sawn wood, were imported last month, and the sales have been by private treaty. The delivery of oak logs has been light, and that of waggon planks moderate; the stock of the latter is now heavy, and the prices are low, and show no signs of improvement. For walnut of prime quality there is a steady demand, and at fair prices; of satin walnut there is a heavy stock, and the prices are very low. There is no Honduras mahogany in stock, and sound logs are in steady request.

Gaseous and Liquid Fuel.—Under the title of the Gaseous and Liquid Fuel Supply Company, Limited, a company has just been registered to take over the patents of Mr. B. H. Thwaite, C.E., F.C.S., of this city, for generating water gas and other descriptions of gaseous fuel, for gas motors, gas furnaces, and for heating purposes generally, and for the application of Mr. Thwaite's patents for heating and lighting with liquid hydrocarbons. The company will establish a fuel testing laboratory, and act as guarantors against smoke nuisance fines. It will be seen that the objects of the company in effecting fuel economy and preventing smoke are likely to be a public advantage.

SHEFFIELD, 9th May, 1888.

Trade Prospects.—There is a confident tone in Sheffield trade. Buyers are purchasing carefully, in the expectation that the prices may decline still further; nevertheless there is a large amount of business being transacted, and money is becoming more plentiful. The town is now practically free from small pox, and merchants, travellers, and country buyers are resuming their trade connections with Sheffield.

Digitized by Google

Perhaps in no previous period of its history has the place been busier with orders. In some of the more noted branches of local trade the men are working overtime, and the houses are steadily developing new markets. Although the American inquiry for nearly all kinds of hardware is on the decrease, the Colonial and other distant customers are inquiring eagerly for Sheffield made goods, and the South African, Chinese, and Japanese markets are rapidly extending.

Iron and Steel.—The output at a few of the local and district furnaces is very satisfactory, but there is not a great demand for iron. Pig is in fact very cheap, and in some cases it scarcely pays to make it. For foundry use iron can be bought at from 32s. 6d. to 40s., and forge is selling at from 29s. 6d. to 33s. 6d. Bessemer is going well at about last week's quotations, and orders for billets are increasing almost daily. The converters are kept going at some of the Sheffield works, and the output has never been larger than it is at present. The armour plate departments are revealing signs of greater activity. Further orders have been received at the Atlas and the Cyclops Works; and Messrs. T. Firth & Sons are also well off for orders. At Messrs. W. Jessop & Sons' one or two valuable contracts have been entered into recently, and in spite of very keen competition they are finding a very satisfactory market for their special steel and crucible cast steel castings. Railway material continues in good request. Messrs. Turton & Sons are very busy on railway springs, and Messrs. Cammell & Co. and the Phœnix Works are turning out an enormous quantity of steel rails. The decision to free railway material for India from dock and harbour dues should benefit Sheffield trade, for it practically amounts to a reduction in carriage. Heavy machinery, edge tools, and cutlery are in better demand.

Local Exhibits.—At the Glasgow Exhibition there are to be seen some steel faced armour plates from the works of Messrs. Charles Cammell & Co., as well as examples of crank shafting for marine engines, gun forgings, and railway material.

LEEDS, 9th May, 1888.

An Improved Method of Heating Tram Cars and Railway Carriages.—A very simple and apparently effective method of heating tram cars is now being tried at Bradford. The method has been patented by Mr. J. Langfield, of Tyldesley, Lancashire, who has given attention to heating tram cars and carriages for some years. His arrangement consists of a horseshoe-shaped heating chamber, made of iron or copper, which is placed in the locomotive smoke box. To this chamber a pipe is affixed, through which air from the outside is conveyed to the interior of the chamber, and a further pipe conveys the heated air from the heating chamber to the floor of the cars. The air thus heated is allowed to diffuse itself throughout the interior of the car. When more than one car is drawn by the tram engine, the same apparatus may be used to heat two or more cars by simply arranging for the heated air to be conveyed along a pipe under the car, having flexible couplings to connect with the rear cars. This method has been at work during the winter months, and with an outside temperature of 37°F. the air in the car had a mean temperature of 53°F., which was found quite sufficient for the comfort of the passengers. The inventor claims that his arrangement is specially suited for the warming of railway carriages, and that the increase of temperature in the compartments would be obtained entirely from the waste heat, and without the constant expense connected with the use of gas or oil for heating purposes. Referring to this method, one of the officials of the Bradford and Shelf Tramway Company, Limited, stated that "the apparatus fixed on our No. 10 engine and car is working very satisfactorily indeed. The travelling public on our line are very outspoken in their praise of the comfort it gives."

NORTH STAFFORDSHIRE, 9th May, 1888.

North Staffordshire Tramways Company.—On account of the action of the Stoke Town Council, the application of this company for a renewal of their license to use steam power was temporarily refused, with the result that for some days the district between Stoke and Longton was deprived of this means of transit, much to the inconvenience of the travelling public. The Council complain of the quantity of sulphur and gas emitted by the engines, and the dilapidated condition of the setts on the tram roads. Major-General Hutchinson has been to inspect on behalf of the Board of Trade, and as a result of his report and certain guarantees consequent upon it, given by the Tramway Company, the license has now been renewed, and the trams are running as usual.

Brussels Exhibition.—Several local manufacturers have sent exhibits to Brussels, amongst which that of Messrs. T. Forrester & Sons, of Longton, consisting mainly of vases of a new style of ware lately introduced by that firm, is of conspicuous merit. A good position has been secured by Messrs. Forrester, and the exhibit will do much to prove the continued excellence of British manufactures to Continental visitors to the Exhibition.

BIRMINGHAM, 9th May, 1888.

The Hardware Trade.—Business in these branches of industry is not so active as it was at the corresponding period of last quarter, but the improvement in the weather is leading to more activity. The inflation in the copper market continues to make itself felt, especially in the case of firms manufacturing heavy goods, such as sheets and large tubes. A considerable amount of distress is reported from Selly Oak, a suburb of Birmingham, where two large concerns, Messrs. Elliott and the Birmingham Battery and Metal Company, carry on business. The business of these firms is suffering severely, and the workmen are either unemployed or working only a few days a week. The heavy stocks in the hands of some firms consuming the alloys of copper have up to the present helped to tide them over the difficulty. Before the action of the syndicate commenced, copper was exceptionally cheap, and many concerns had large quantities of the metal lying unused. By melting up all available metal, and utilising unimportant patterns, persons in this position have hitherto avoided the necessity of purchasing to any extent. The metal rollers report a fairly active market, and seem to entertain an expectancy of continued high prices. Wire workers are very busy, and makers of hollow ware are fairly well employed. Screw makers also have plenty of work on hand, but complain of the narrowness of profits. Rule makers, gun makers, and pewterers are also reported to be well employed. Among foreign markets, Holland, Germany, and Spain are just at present the best; the French demand is only moderate. The prolonged discussion in America on the tariff question is unsettling business with that country; but India, the Cape, and Australia are taking a fair amount of hardwares. There is some activity on account of Canada, and Burmah is coming forward as a consumer.

LEICESTER, 9th May, 1888.

Wool Spinning and Yarn Trades.—The wool trade remains in a very unsatisfactory condition, and the recent London sales have not given an appreciable firmness in the local market, and prices are as low as they were three years ago; and it does not appear that there is any great probability of improvement. The new clip, being now very near, gives a slight firmness in prices; but staplers are loth to operate with growers and country dealers at late quotations, as they find great difficulty in effecting sales. Spinners are, as a rule, but very moderately employed; hence their operations are restricted, and their purchases are for only very immediate requirements. The flatness of the spinning branch, and the unstable condition of the raw material market, make the general condition of these trades very unsatisfactory. Yarn merchants are not doing a large business, on account of the unsettled state of market prices in wool.

Boot and Shoe Trade.—A much needed improvement has taken place in this important industry, and firms generally are now more fully employed. Both retail and wholesale buyers are operating more freely in summer goods, and a continuance of good trade is anticipated. In the leather trade, merchants find great difficulty in doing satisfactory business. Competition is extremely keen for orders, and quotations are at a very narrow margin of profit. The tone of the market generally is very low, and prices are remarkably unstable.

BARROW-IN-FURNESS, 9th May, 1888.

Iron and Steel.—There is no change to note in the quiet tone of the hematite pig iron trade. The demand is anything but active, but there is nevertheless a moderate forward inquiry. The consumption of hematite is well maintained, and the deliveries both on home and foreign account are very large. Prices show no variation, and mixed parcels of Bessemer pig iron are quoted at 42s. 6d. per ton net f.o.b., and forge and foundry qualities at 41s. 6d. per ton. In steel there is a good market; but sales are not heavy, owing to the fact that makers are fully sold forward, and are not devoting their attention to negotiating forward sales. Rails are in good demand at last week's prices—viz., £3. 17s. 6d. per ton net f.o.b. for heavy sections, and £4. 2s. 6d. for light sections. There is a very full demand for ship plates and angles, which have been largely sold. Current prices represent £6. 15s. for plates, and £6 for angles. A prominent feature is the large output of tin bars. A brisk business is doing in billets, and in wire and hoops. Iron ore is in very steady demand at from 8s. 6d. to 11s. 6d. per ton net at mines.

The Petroleum Trade.—Arrangements have been completed with the most influential syndicate in the Russian oil trade for the importation of petroleum from Batoum to London and Barrow, the two depôts for the trade. At Barrow the contract has been let to Mr. David Caird for the construction on the docks at Barrow of large storage tanks capable of holding 8000 tons of petroleum. Two large steamers of 3500 tons are being built on the Tyne for the Barrow petroleum trade, and it is expected they will be delivered in September. The principals of the new company are Messrs. Wallace Brothers, of London, and the managing directors, Messrs. MacAndrew & Co., London.

MIDDLESBROUGH, 9th May, 1888.

Pig Iron.—The pig iron market is still quiet, and is declining as far as prices are concerned. No. 3 G.M.B. can be had for 31s. 3d. per ton, and at an even lower rate; but there is very little business being transacted, as buyers are confident that prices will remain as they are for some time. In the meantime Continental buyers are replenishing their stocks at a rate that has raised the expectation in the minds of makers that better prices must shortly rule. Warrants have fallen as low as 31s. 1d. per ton cash. These low prices are the inevitable result of the very low price of Scotch.

Exports of Pig Iron.—Exports are still very heavy; those to Scotland are falling off, but those to the Continent are still on the increase. It is considered, however, that the latter must soon be reduced when the customers are fully supplied. As far as the year is gone the exports are most satisfactory. For the four months ending 30th April they amounted to 298,196 tons, as against 250,597 tons during the corresponding period in 1887, 219,485 tons in 1886, and 264,495 tons in 1885.

Iron Masters' Returns.—Four furnaces have been taken off hematite and put on to Cleveland. The stocks of pig iron, which on the 31st March amounted to 610,698 tons, on the 30th of April amounted to 586,492 tons, being a decrease of 24,206 tons for the month of April; 15,494 tons of these were taken from Connal's stores. During the last three months the decline in stocks has been fully 57,000 tons.

NEWCASTLE, 9th May, 1888.

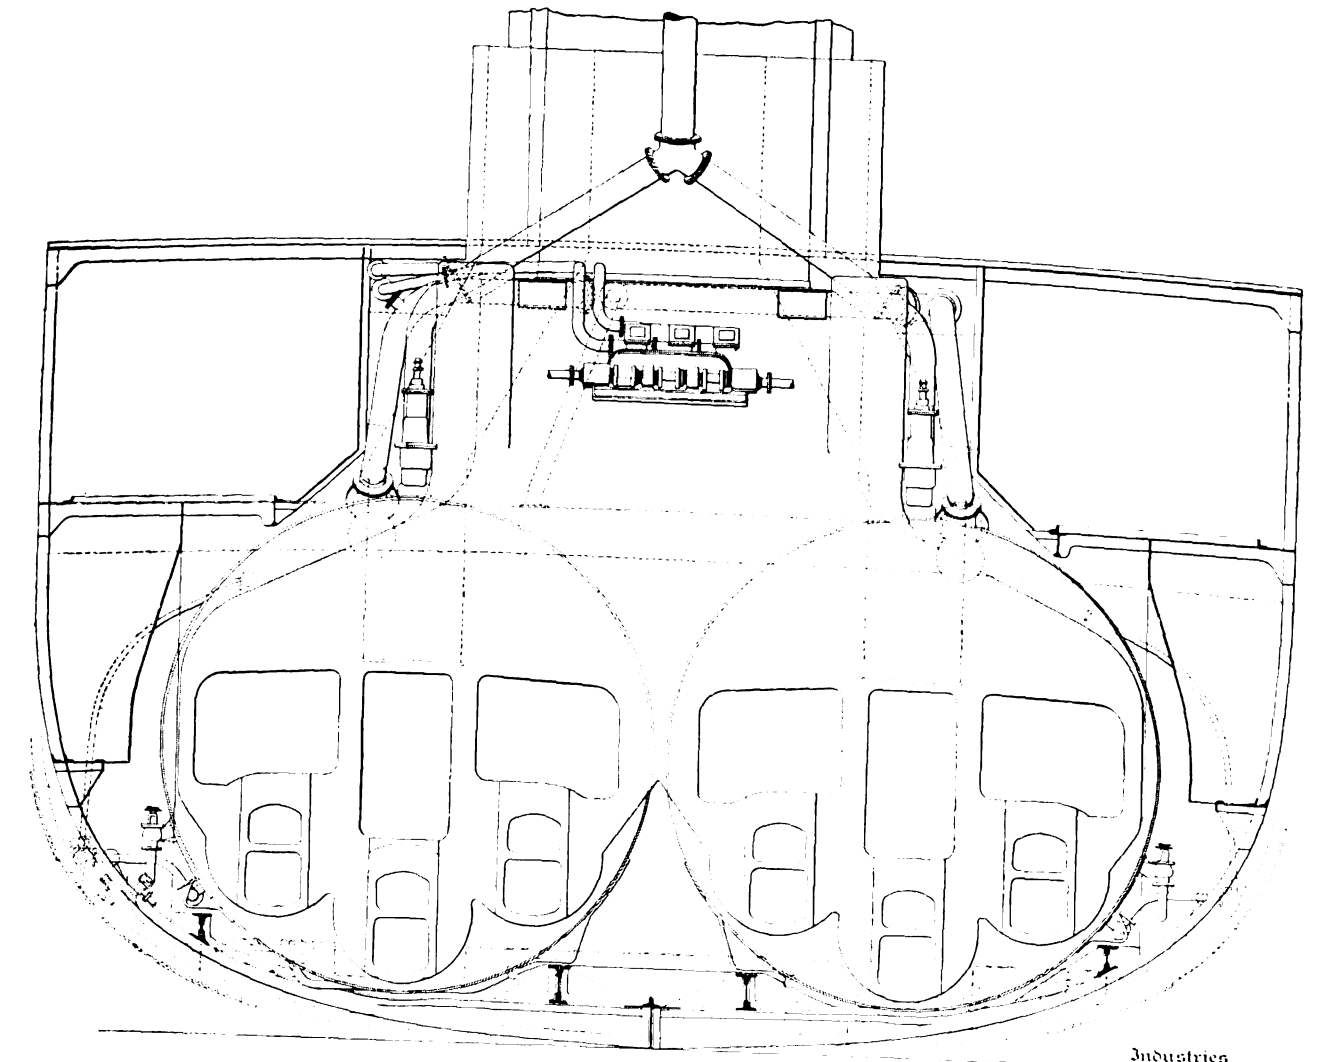
Chemicals.—At this season of the year the demand for bleaching powder and other products of the chemical factories usually exhibits a stronger tone, and that circumstance somewhat lessens the significance of the improvement which is now taking place in the various branches of the industry. At nearly every important manufacturing establishment on the Tyne the output of the special commodities has increased, and in some instances to a very marked extent. The circumstances of the industry, however, are not such as to warrant the assumption that any exceptional development of activity is imminent, and the expectations of manufacturers will probably be fully satisfied if the present moderately prosperous state of business is maintained during the summer months. Very rapid progress is being made with the new works being erected by Messrs. Allhusen & Co., for the extended manufacture of caustic soda, and the same may be said with reference to the sulphur recovery plant being put down by the Jarrow Chemical Company. The demand for chemical manures is active, and manufacturers are now busily engaged in fulfilling new contracts, as well as others that were entered into some time ago.

Copper.—At the copper works business is somewhat dull; but stocks are being reduced, and other signs are to be noticed which tend to show that a return of briskness is not far off.

Lead.—In almost every instance the lead works on Tyneside are busy, and there appears to be reason to expect a continuance of this healthy state of trade.

Electric Lighting.—Messrs. Clark, Chapman, Parsons, & Co. have obtained some good orders for electric lighting plant. In the building, which was expressly erected for this kind of work, there are in course of construction several patent turbo-electric generators of various sizes up to five hundred lights; and independently of any further orders which may be obtained, the competition of these generators must necessarily keep up the present briskness for a considerable time to come.

DUNDEE, 9th May, 1888.



Flax and Jute Trades.—Business in the staple trades of the town and district has been fairly steady during the past fortnight. The jute branches are rather unsettled. The period agreed upon for running short time has expired, and an effort is being made to continue the decreased production for another three months. One or two leading firms, however, seem disinclined to give in their adherence to any renewal. Transactions in the flax market are somewhat limited, buyers being well supplied by the new arrivals. Now that navigation is opened consumers are in a better position to provide for current wants. Flax and tow yarns are selling more freely, but spinners have not been able to obtain any decided advance on previous quotations. Linen goods are in steady demand, and in the Fife district manufacturers are well engaged. Jute on the spot meets a fair inquiry; but buyers are offering very low prices, and most of the parcels in dock for sale are consequently being warehoused. For distant shipment prices are steady. Jute yarns are in somewhat better request, and a small advance is asked; but buyers have been holding off until the result of the short time negotiations is known. In jute goods the transactions are limited; but there is considerable inquiry, and if manufacturers would meet buyers some fair orders might be placed. Bagging and sacking are steady at late prices, and tarpaulin is in good demand.

Seal and Whale Fishing.—The Newfoundland seal fishing season has just closed. Four Dundee vessels were engaged, and their united catch is 66,900 seals, calculated to yield 800 tuns of oil. Last year five vessels were employed at the fishing, and the catch was 51,650 seals. Formerly it was the regular practice of the sealers to discharge their cargo at St. John's, and proceed to the Davis Straits whale fishery. This year two of the four vessels which were at the seal fishing returned home directly. The whale fishing has been unremunerative of late years, and in some cases, where the sealing paid, the profit has been lost in the Davis Straits voyage. However, there will be seven Dundee vessels altogether at the whale fishing this season, including the two which have gone on the sealing trip.

END ELEVATION.

GLASGOW INTERNATIONAL EXHIBITION, 1888.

THE official opening of the Glasgow Exhibition by the Prince and Princess of Wales took place on Tuesday, the 8th inst. The weather was all that could be desired, the crowds in the streets were enormous and exuberantly loyal, the inaugural music was magnificently rendered by choir and orchestra, the civic dignitaries were apparelled with becoming splendour; in short, the function was brilliantly successful from every point of view. The opening ceremonial consisted of the presentation to the Prince of Wales of a gold key, given by Messrs. Chubb, wherewith to open one of the gates of the grand entrance, and the presentation also of the conveners of committees and of the principal officials of the Exhibition. Subsequently the "Inaugural Ode," written by Mr. Robert Buchanan, and set to music by Dr. A. C. Mackenzie, the well known composer, was sung by the Choral Union, with orchestral accompaniment, Dr. Mackenzie conducting his own music.

When the formal ceremonial of the opening was over, the Royal party made a progress through the picture and sculpture galleries, and then spent a considerale time in the women's industries section. After a short interval they passed down the main avenue to the Indian court, and then on to the machinery annexe, the conveners of the respective sections conducting the party through their departments. The most impressive sight in such pageants is always the crowd, and in this case the formation of the ground immediately surrounding the park was singularly [illegible] view points for the vast crowd [illegible] It is hard [illegible] of people, park alone, while the numbers in the streets must have reached many hundreds of thousands. The Exhibition buildings were filled with a throng of privileged ticket holders, and the grounds were also occupied by season ticket holders, besides large bodies of military and volunteers, including about 3000 boys of the Boys' Brigade. The promenade in front of the University was reserved for holders of privileged tickets, and, like all the high places round the Exhibition grounds, was crowded with sightseers.

During the few days prior to the opening, exhibitors had made frantic efforts to get their effects in order, and that with so much success that practically nothing remained to be done. The cases that only a few days before blocked the passages, and gave the halls an unfinished air, have disappeared, and everything is as trim as if all had been in place for months. Only those who have seen the growth of an exhibition can realise by how much hard labour, and by what prodigies of management, what looks like an Aladdin's palace has been reared and filled in a few months. The experience and the patience of Mr. H. A. Hedley, and of his assistant, Mr. Thomas Hedley, as well as the powers of the conveners of the sections, must have been severely taxed. The successful issue of their efforts even so far does them the most conspicuous credit. It is understood that the capital sum expended upon the buildings and the grounds, amounting to upwards of £70,000, has already been recouped by the proceeds of the sale of spaces and of season tickets. Thus, only the current expenses require to be provided from the amount of cash paid at the gates. This practically secures financial success, so far as the Executive are concerned. The financial results to the exhibitors are not so easily estimated, either by themselves or by anyone else. Some of the exhibitors, indeed, are there more from patriotic fervour, or shall we say the love of fame, than for any result realisable in hard cash.

These exhibits are, however, among the most valuable from an educational point of view, and in such the Glasgow Exhibition is notably rich. The courts, indeed, form the most admirable auxiliary to the technical school in studying almost any of the leading branches of industry. It is an industrial museum, not of archæological but of present interest.

It has successfully passed the testing point of all exhibitions, viz., how to strike a medium between the bazaar on the one hand and the museum on the other. It is not easy to trace the precise lines of influence of exhibitions viewed as means of education; but there can be little doubt that only a quickened and more intelligent grasp of industrial processes can result from the opportunities afforded by so varied and valuable a collection of machines, manufactures, and natural products as that now in the West End of Glasgow.

PADDLE ENGINES OF THE MANX LINE STEAMER "QUEEN VICTORIA."

IN our issue of the 27th January last, we published a two-page engraving giving a general view of the engines of the "Queen Victoria," constructed by the Fairfield Shipbuilding and Engineering Company, Limited, Glasgow, and we now, as promised, publish above and on our double page supplement this week an end view of the boilers and a longitudinal elevation of the engines and boilers. Illustrations showing an end view of the engines, and a plan of the engines and boilers, will be given in a future issue.

FRIDAY, 11TH MAY, 1888.

ITALIAN INDUSTRIES.

THE unpretentious Exhibition which opens at Earl's Court to-morrow, is likely to be remembered as one of the landmarks in the history of Italian industrial life, and as a point of special interest in the development of British trade with Italy. Whether we regard it merely as a collection of raw produce and manufactured goods, illustrative of the industrial capacity and commercial position of one of the great nations of Europe, or as an event significative of progress in industry and commerce in a rival people rising into political eminence, the show at Earl's Court is worthy of attention. As a mere exhibition, it will excite surprise. The Italy of to-day is very different from the Italy of a quarter of a century ago; and only those who have carefully watched the progress of affairs in the peninsula are fully aware of the great advances that have been made. The Italy of the past was a nation of consumers, producing but little, and buying largely in our own markets. We have, in consequence, come to regard the markets of Italy as outlets for our produce, for which we have to struggle in keen competition with rival producers in neighbouring lands; but many of us have hitherto failed to realise the fact that our customers are gradually becoming themselves producers. Visitors to the Exhibition will encounter this fact in all its force, and the revelation is likely to be startling. It will appear with surprising impressiveness that some, at least, of our most important outlets are gradually and surely closing against us; that our hitherto excellent customers are striving with some success to render themselves independent of our manufactures; and that the day is not far distant when they may even appear as formidable rivals in foreign neutral markets. Considered as an historical event, the Exhibition marks the close of what may be described as the initial stage in the development of the industrial life of Italy. The manufacturers of the peninsula manifestly feel themselves able to maintain their position as producers capable of competing on equal terms with their older and in some respects more favoured rivals. The boldness with which they assert themselves is evidence of this, for it is a bold step to set themselves down in our midst, bringing with them samples of their productions, and challenging comparison with the products of our old established industries. We see in this step another manifestation of that spirit of enterprise, that vigorous life and sturdy manhood, which has of late impelled the Italians to aspire to the position of a great military and naval power. The degree of success already attained in the latter direction may be taken as a guarantee of equally great achievements in trade and industry.

One of the greatest hindrances to the development of manufacturing industries in Italy in past times was the want of fuel. Nature has been niggardly of her gifts in this respect, for though lignite exists in abundance in some localities, the country is void of the better descriptions of coal. But the last twenty-five years has been a period of constant progress in knowledge, and this advance in the ways of science has enabled us to burn fuel more economically. The work obtainable from a ton of coal has gone on year by year increasing, till now it has become possible for countries where coal is scarce to carry on great industrial operations with imported coal. The favourable situation of Italy, with its extensive sea board, cheap labour, and technical skill, more than counterbalances, in present circumstances, the disadvantage of heavy charges for the long carriage of coal. It was not likely that a shrewd people like the Italians would fail to perceive the altered state of things, or perceiving it would neglect to turn their opportunity to account. Accordingly we find them establishing industries of various kinds throughout the country, and supplying their wants largely from their own manufactures. Some notion of the progress made in recent years may be acquired from a comparison of the quantities of English coal imported by Italy annually. Thus the increase has been from 2,212,111 tons in 1883 to 2,354,103 tons in 1884, 2,703,471 tons in 1885, 2,852,204 tons in 1886, and 3,186,854 tons in 1887. We have in these statistics evidence of rapid growth. The iron industry has developed itself wonderfully within the last ten years, the engineering trades have followed in a way that will probably astonish many visitors to the Earl's Court Exhibition, and the textile manufactures have kept pace with the progress made in these heavier trades. The silk manufacturing industry is making headway against French competition, and cotton goods are turned out at prices that compare favourably with those of British manufacture. Hence we have to take the native industry into account in all our dealings with our Italian customers. Italy is no longer an open market, but one which, for many of our manufactured goods, is being gradually closed against us.

The first impression, then, upon the mind of the visitor to the Italian Exhibition, will be one of discouragement. Manifestly there are grounds for serious apprehensions concerning the future of our trade with a country which has been in the past among our best customers. But there is another, and happily a brighter, side to the question. Amid these changing circumstances, it will be our own fault if we fail to retain our hold upon the Italian markets. Thriving communities are ever creating fresh wants, a disposition which growing industries tend to foster. Hence the Italian demand will, for a time, keep pace with the increase in the power of production; and for this reason our trade is not likely to suffer diminution in the immediate future, provided we are able to hold our ground against the competition of Germany. But the time is certainly approaching when the needs of our Italian customers will, in some classes of goods, find full satisfaction at home; and if we are to retain undiminished the total volume of our trade, we must take care that while old markets are being closed against us, new outlets are being found. Here lies the great value of an exhibition like that which is about to open in London. From the evidence there brought together, manufacturers will learn in what direction and in what degree their goods, now freely bought, are likely to be ere long superseded by home products, and they will be able to discover at the same time what may be substituted for them with the best chance of success. This knowledge the Germans are now seeking through their agents stationed in the chief centres of Italian industry, and already they have turned to good account the information thus acquired. In textile goods especially, and in some classes of manufactured iron goods, they have largely increased their trade within

Digitized by Google

the last five years. It is for us to follow their example, and if the Exhibition serve no other purpose than to impress upon British manufacturers the necessity of inquiring more carefully into the matter than they have hitherto done, it will greatly benefit British trade. The time is opportune. Political animosities have brought about estrangement between Italy and France, and a consequent war of tariffs is diverting the current of trade from its former channels. To obtain a share of this trade our enterprising rivals, the Germans, are exerting themselves to the utmost. We, on our part, must also bestir ourselves, and the event which the Lord Mayor will inaugurate to-morrow comes as a timely reminder of the opportunities which are now ready to hand.

PROGRESS IN JAPAN.

The Japanese have for a considerable time expressed their determination to make their country the "Britain of the East," and the progress which has been made in arts and manufactures and in means of communication during recent years seems amply to justify that determination, and to promise that the day is not far distant when Japan will not only be able to supply almost all her own wants in the way of manufactured goods, but will also be one of our most active competitors for the trade of the vast empire of China, which is often mentioned as likely to be our best customer in the future. The Japanese set about their work in no haphazard manner. They had a clear idea that underneath any real industrial progress there must be a good foundation of scientific training, and they founded colleges and schools which, in some respects, are superior to those in this country. In science and engineering special facilities were given to the young Japanese, and they entered on their studies with most enthusiastic ardour, and now in every province of the country we find graduates of the colleges superintending public works and private enterprise. During the past two years especially there has been an almost feverish growth of trade and of joint stock companies, a great part of which is no doubt legitimate; but it is to be feared that some of it is of an entirely speculative nature, and unless this speculative spirit be moderated, it will lead to a very acute financial crisis, and induce reaction. In fact, this great activity is largely a reaction from the great depression of the past few years, and from the changes induced by the financial policy of the Government. Seven or eight years ago it was resolved to contract the volume of the paper currency, and this contraction was accompanied by all the phenomena incidental to such operations. Prices fell, and the fixed charges of property or industry grew heavier, and capitalists withdrew their money from private undertakings and invested in Government securities. Consequently the prices of these were driven up till they attained a figure at which the return was small; and now that the finances of the country have been consolidated it is only natural that capital should return to more profitable investments. Hence the large increase in limited liability companies, with all their advantages and disadvantages; for the competitive spirit has extended to Japan, and there are now to be found in that country, as in this, men who seem to live on the gullibility of their neighbours. All this time Japan labours under the extra-territorial system of jurisdiction which most effectually prevents the introduction of foreign capital and skill; for, although the Government is quite willing to allow the country to be thrown open, it can only do so when foreigners are willing to place themselves under the jurisdiction of her territorial courts. This has always been resisted by the Treaty Powers, and Japan, rather than give way on the point, has resolved to develop her industrial resources without the pecuniary aid of foreigners. We feel confident that if the British Government was fully informed regarding the position of Japan, it would not insist on carrying on the present system.

From Foreign Office and Consular reports, from the correspondents of the leading daily journals, and especially of the *Times*, and from private letters, we have obtained information regarding the recent development of industrial enterprise in Japan, and from these sources we propose to note a few of the most prominent items. Perhaps the most important feature is the increase in railway construction. That was begun in 1868 with funds borrowed from abroad, and at the end of 1886 the total mileage was 370, while during 1887 there were 151 miles of railway completed. Until 1882 the Government was the sole constructor; but in that year a company was formed for constructing lines to the great silk districts north-west of the capital, as well as to the northern provinces, and the Treasury guaranteed 8 per cent. per annum on its paid-up capital. Of the total length of 521 miles of railway constructed, 282 have been built by this company, and the remainder by the Government. To give some idea of the recent progress, it may be mentioned that between 1868 and 1877 the annual rate of construction was nine miles; between 1878 and 1880 it was five miles; between 1881 and 1883 it was 36 miles; between 1884 and 1886 it was 61 miles; and in 1887 it rose suddenly to 151 miles. The first roads built by Government cost more than £10,000 per mile; those last constructed cost only about £3,600 per mile. This is largely accounted for by the fact that all the recent lines have been constructed by Japanese engineers, and Japanese materials have been utilised as much as possible, and the whole service, after construction, is entirely managed and worked by Japanese, with rare immunity from accidents or blunders. The lines of the Japan Railway Company are paying an annual dividend of 10¼ per cent., with every prospect of still larger profits. Their working expenses are about 45 per cent. of the receipts. Last year was remarkable, not only for the rapid extension of the railway system, but also for the fact that eleven railway companies were started, with an aggregate capital of thirty-two millions of dollars. If the treaties were revised, and extra-territoriality got rid of, a wide field would be opened for the enterprise of foreign capitalists.

In a recent issue (see *Industries*, Vol. IV., page 214), we gave an account of the development of the telegraph system in Japan, and to that we would refer for particulars. We need only mention here that the total length of lines at the end of the year 1886 was 5578 miles, and during that year 166 miles were constructed. With regard to shipping in the possession of Japanese, we have not exact statistics; but during the last three or four years large numbers of vessels have been built for Japanese owners, and their mercantile marine is now very considerable, while their navy is not by any means to be despised, as it would form a most important factor in any naval action which might be necessary in the Eastern Seas. A most important work has just been undertaken by the Government in the formation of a naval station at Kure, a well chosen spot in the Inland Sea, within a few miles from Hiroshima, the frontage of the proposed dock yard being about a mile and a half in length, and other smaller naval stations are being organised. These would be found most useful in case of war, and when we mention that during last year 948 foreign vessels entered Japanese ports, with an aggregate tonnage of 1,269,429, it will be seen that the interests of foreign nations involved are very considerable.

But the enterprise of the Japanese has not by any means been confined to larger works of communication or carriage. The Tokio correspondent of the *Times* recently summarised those undertaken during last year. He said that in the three cities of Tokio, Osaka, and Kioto, no fewer than 111 large companies, industrial or commercial, were formed during the year, with an aggregate capital of $21,500,000. Besides these, a number of smaller undertakings found promoters and supporters throughout the provinces. During the same period thirteen banks made additions to their capital, the sum of such increments being $18,000,000. If to these amounts be added the $32,000,000 representing the capital of the eleven new companies already mentioned, it will be seen that shares in various public undertakings to the extent of more than $71,000,000 were taken up by the people during the year 1887, the total representing an average of nearly $2 per head for the entire population. Among the 111 companies all sorts of enterprises are included. There are companies for cotton spinning, paper making, dyeing, glass blowing, lumber dealing, tea and silk exportation, horse breeding, land transport, and engineering companies, as well as others for the manufacture of porcelain, lacquer, bronzes, and other art objects, and a host of other commodities. Among all these the growth of cotton manufactures is, perhaps, the most manifest and significant. At the end of December there were no fewer than twenty-two spinning mills at work, representing 76,000 spindles, and a yearly output of 1,320,000lb. Further, eight large new factories, with 117,000 spindles, had been started, and were being brought rapidly into working order. The *Times* correspondent adds that the meaning of this is plain—Japan intends to make her own cotton goods instead of buying them from abroad. She cannot as yet supply herself with the material, and is therefore obliged to import considerable quantities. But everything points to her success as a manufacturer. She is within easy reach of great cotton growing regions; she possesses an unlimited supply of probably the cheapest labour in the world; her art artisans have no equals elsewhere; and her people enjoy the blessings of settled government and full security of life and property. While we wish Japan all success in her efforts, we at the same time hope that British merchants will clearly realise the facts of the case, and not permit themselves to be overtaken by the enterprising "Britons of the East" in the race for the leadership of the industry of the world.

THE EDISON GLOW LAMP PATENTS.

Our report of the proceedings in this case in our last week's issue concluded with the commencement of the cross-examination of Professor Crookes. In reply to further cross-examination, the witness referred to several passages in Edison's subsequent patents, in which was pointed out the necessity of careful carbonisation to prevent warping, twisting, &c., and to allow for contraction, which he stated to be inevitable; and speaking of Edison's suggestion to coat the filament with a non-conducting non-carbonising substance, he pointed out that the action of these substances upon the filament when placed in the lamp would depend to a very great extent upon the condition of the filament itself. If the filament were a hard homogeneous carbon, and the silicate easily fusible, the silica might run off without attacking the carbon, whereas, if it were a soft porous carbon, it would absorb a fusible silicate like a sponge, and be destroyed when the temperature rose high enough. A lamp handed to Professor Crookes by the Attorney-General, which had been coated with a non-conducting non-carbonising substance was, in Professor Crooke's opinion, made with a filament of parchmentised thread, that is, thread which had been treated with an acid prior to carbonisation. Professor Crookes did not consider this filament was a fair example of the Edison filament described in the specification. He also stated that he had himself experimented with a very large number of substances as coatings for the filaments, and without a single exception he had found them all the reverse of beneficial, by reason of their diminishing the radiating power of the carbon. Returning to the subject of carbonisation, it had been suggested to the witness, in cross-examination by the Attorney-General, that gases were given off during carbonisation, and expelled the air from the crucible. On this point Professor Crookes stated that at the comparatively high temperature at which these gases would be formed, the mobility of the molecules would be much increased, and they would diffuse out rapidly at the same time that the atmospheric air would diffuse in: the luting of the crucible would by this time have become quite dry, and permeable to gases.

The next witness called by the defendants was Dr. Frankland, who was examined by Mr. Graham. He stated that he had lighted his house five or six years ago with incandescent lamps which he had obtained from the Swan Company before their amalgamation with the Edison Company. He remembered seeing the exhibition of lamps at Mr. Spottiswoode's house in December, 1880, on which occasion Mr. Swan explained their construction. The first time he saw an Edison lamp was at the Crystal Palace Exhibition in 1882, when Mr. Sprague, who was Mr. Edison's agent, presented the witness with an Edison lamp, which he produced. This, in Dr. Frankland's opinion, was made of a bamboo filament, and was not made according to the directions contained in the specification now in question. The carbon filament appeared to have been mounted to the platinum leads by some electrolytic process, and the witness had never seen, in the market, an Edison lamp in which the filament was mounted in the manner described in the specification. Dr. Frankland stated that he had endeavoured to make a putty-tar filament, but had not been able to roll it out finer than one millimetre in diameter. He did not attempt to carbonise any of these filaments himself; but he saw an experiment made by Professor Crookes, in which the crucible had not been packed, and all the filaments, including some made of structureless cellulose, were entirely burnt up, leaving nothing but ash. He corroborated Professor Crookes as to the effect of coating the filament with the non-conducting non-carbonisable bodies, and also as to the effect which the carbons would produce on the platinum if the platinum were attached to the filament before carbonising. In his opinion, at the date of Edison's specification, the word filament had acquired no technical or conventional meaning, except in botany, and there it meant, in some cases, a thing of considerable diameter as compared with its length. Speaking of the experiment which Professor Crookes made, where a fine pencil was cut from a stick of lime, which had been impregnated with carbon by flashing in a hydrocarbon gas, and the pencil then placed in a lamp, Dr. Frankland stated that he was looking through a spectroscope at the time, and after a minute or two he saw the calcium hues in the spectrum; soon afterwards the lamp broke. Dr. Frankland had carried out Despretz's process, and produced a material which was identical with Cheesbrough's. If the platinum had been placed in the carbonising chamber, and had thus to some extent been converted into a carbide, then at the time of sealing the platinum into the glass a considerable length of the platinum would be heated to a red heat, and the carbon in the carbide of platinum would burn off, leaving the wires in a very porous state. Dr. Frankland was then cross-examined at very considerable length by the

Digitized by Google

Attorney-General. The witness was the principal scientific witness in the action which was brought about two years ago by the present plaintiffs on the same patents against the well known firm of Woodhouse & Rawson. He admitted that the only experiments which he had seen since that trial were those performed by Professor Crookes, and further that during that trial he had not said anything about the insufficiency of Edison's specification, or on the point which had been raised recently about the formation of carbide of platinum. The witness had stated at the last trial that in an old specification filed by Pulvermacher there were sufficient directions to enable a skilled working man to make a carbon filament such as Pulvermacher describes; and he admitted that he was still of the same opinion, but that more specific instructions would be required to enable a working man to carry out the process, because carbonisation, so far as it was known at the date of Edison's patent, always meant partial combustion of the thing being carbonised. Dr. Frankland was then asked by Sir Richard Webster whether he was not aware that in February, 1880, there was an exhibition of Edison lamps in Queen Victoria-street, on which occasion Dr. Fleming explained their construction. Dr. Frankland stated that he was not aware of it. The witness was then asked some questions about the experiments with the lime pencil impregnated with carbon, and admitted that he had not made the experiments for himself, but was present when Professor Crookes carried them out. He said that the bright calcium hues were due to the metal calcium being in a state of vapour, and that calcium would only pass into that state at such high temperatures as that of the electric arc. On re-examination by Mr. Finlay, Dr. Frankland stated that the list of infusible non-conducting substances previously referred to as having been put in by Professor Crookes, specifying some forty or fifty bodies, did not by any means exhaust the number of bodies answering to that description, but was a list of those which were most likely to succeed, although in his opinion not one of them would succeed. He added that this point on Cheesbrough's specification, and the analogous one as to non-conducting non-carbonisable bodies mentioned in Edison's specification, was not referred to at the last trial, on which occasion the sufficiency of Edison's and Cheesbrough's specifications was hardly mentioned.

Dr. Tidy, who had given evidence on behalf of the plaintiffs as to Cheesbrough's patent at the last trial, was now called, and examined by Mr. Finlay, on behalf of the defendants. He stated that he had put fifty filaments into a crucible, and carefully luted the top and raised it to a carbonising temperature, and had found nothing but ash on opening the crucible. He then filled the crucible with charcoal, and succeeded. He then tried making putty-tar filaments, and pointed out that Edison gave no directions as to the proportions of tar and lamp black. If you put too much tar, the mixture ran; if you put too little, the substance came to pieces. After a great many trials, he got a filament about $\frac{1}{25}$in. diam., which he carbonised with charcoal; but he found, on opening the crucible, that it fell to pieces. He considered it was necessary to use a mould in carbonising, which would allow for contraction and prevent distortion. Dr. Tidy was then cross-examined by Mr. Aston, and admitted that it was possible to carbonise a cotton thread, but denied that a putty-tar filament could be subjected to a carbonising process, and come out as a filament which could be used. Dr. Tidy had also coated a thread with tar and lamp black, and he had found that the coating cracked in carbonising. He admitted that in one of the specifications prior to Edison there was a description of carbonising carbons to be used for arc lighting in contact with powdered charcoal. Dr. Tidy stated that in carbonising there were two factors which had to be taken into account: the temperature at which the carbonising was effected, and the rate at which the temperature was raised.

Professor Sylvanus Thompson was the next witness. He was examined by Mr. Finlay as the principal witness to speak to the electrical aspect of the case. Professor Thompson stated that he visited the house of Mr. Stearn at Rockferry in the autumn of 1880, and observed that it was lit with electric lamps, the conductors of which were of a filamentous character. He saw many Swan lamps at the meeting of the British Association at York, in August, 1881, and the first time he saw an Edison lamp was at the Paris Exhibition, in September, 1881. Those lamps, he said, would come within the second claim of Edison's specification, but had been made with many improvements not mentioned in that specification. He pointed out nine respects in which they differed from those described in the specification. Professor Thompson then produced diagrams showing the different ways in which lamps could be used, that is to say, in series, in multiple arc, and in a combination of the two. And he explained that the advantage of high resistance in lamps was an advantage external to the lamps; a lamp of low resistance being more durable than one of high resistance. With high resistance lamps small mains could be used, whereas with low resistance lamps the mains would be large. The witness referred to passages in Lane Fox's and Edison's patents prior to the one in question where this had been pointed out, and to a specification of Edison, in which he had himself pointed out the advantages of low resistance lamps in certain cases. He produced specimens of Carré carbons which he bought from Mr. Carré in 1878, which were one milimetre in diameter, and had orignally been one metre in length, and said that at that time they were the most suitable forms of carbon for use in incandescent lamps. Professor Thompson further stated that the real difficulty of fusing platinum into glass depended upon the glass and not on the platinum. Glass differs much in its rate of expansion, and if a glass is taken which has the same rate of expansion as the platinum, there is no difficulty in sealing platinum wires into it. Professor Thompson was cross-examined by Mr. Moulton, and was much pressed for the purpose of elucidating from him that the pencil of lime impregnated with carbon and put into a lamp by Professor Crookes, was not of uniform section, and that the consequence of this would be that at those portions of the pencil where it was thinnest, the heat might have risen to that due to the arc, while the other portions were still at a low yellow heat, and thus a chemical reaction between the lime and the carbon might be induced at one particular spot, while the rest of the pencil appeared to be at a low temperature.

The next witness was Professor Perry, who was examined by Mr. Graham. He stated that one of the great factors which made incandescent lighting possible was the improvement in the dynamo machine. The first Gramme dynamo brought into this country was shown by the witness to a number of scientific gentlemen in 1874, to whom the machine was quite unknown. In 1878 Brush took out his patent for compound winding, but the merits of compound wound machines were not generally recognised until a year or two after that date. Professor Perry stated that in his opinion it would not have been safe, having regard to the nature of the dynamos then in the market, to use a lamp with a carbon conductor much smaller than that used by Mr. Swan. The advantage of the compound winding was pointed out to be that you may switch on a hundred lamps or more, and switch them all off but one, without producing any material difference in the electromotive force. Professor Perry was cross-examined by the Attorney-General, and said that he thought the gold medal which was awarded to Mr. Edison at the Paris Exhibition was not for his lamps alone, but for his telephone, phonograph, and other things also.

Mr. James Swinburne was then examined by Sir Horace Davey. He stated that about 1881 he was with the Swan Company at Newcastle, and that great difficulty was experienced in properly carbonising the filaments. After some weeks of experimenting, the method had been devised of winding the threads on such a frame as that spoken of by Mr. Edward Gimingham. At one time the Swan Company carbonised each filament separately in moulds something like a water colour palette. Mr. Swan, towards the end of 1880, had taken out a patent for carbonising filaments in the presence of powdered charcoal. Mr. Swinburne had tried long ago to carbonise in sand, and had failed, and quite recently he had measured the quantity of steam and air which came off sand, and he found that 140 cub. cm. of silver sand gave off as much steam and air as would burn up twenty-five to fifty filaments. A sample of grey sand tried by Mr. Swinburne of the same volume, gave off 27,000 cub. c.m. of steam and air. Mr. Swinburne stated that he had considerable experience in testing incandescent lamps, and that he did not think the duration tests which had been made by Mr. Gimingham had been sufficiently hard ones. Mr. Gimingham had tested the lamps at about 16 watts per candle power, whereas Mr. Swinburne considered $3\frac{1}{2}$ to 4 watts a more satisfactory test. It was the one which he usually applied. The case was still proceeding at the time of our going to press.

THE IRON AND STEEL INSTITUTE.

The annual meeting of the Iron and Steel Institute was commenced on the 9th inst., at the Institution of Civil Engineers, Mr. Daniel Adamson, the president, in the chair. The gold medal was presented to the President by Sir H. Bessemer, who gave an interesting account of his early struggles to introduce his steel, stating that Mr. Adamson was the only manufacturer outside Sheffield who thoroughly investigated the invention, and that the modern wide use of steel was to a large extent due to his efforts. After thanking the Council for the honour conferred upon him, Mr. Adamson delivered his address, in which he remarked that the total production of manufactured iron in the United Kingdom in 1884 was 2,237,535 tons, against a total in 1887 of only 1,701,312 tons. The production of Bessemer ingots in 1884 was 1,299,000 tons, while in 1887 it had risen to 2,064,000 tons. In 1884 the total production of steel ingots by the open hearth process was 475,250 tons, and the manufacture has increased every year, until it reached 981,104 tons in 1887.

THE LATE SIR CHARLES BRIGHT.

We regret to have to announce the death of Sir Charles Bright, which took place on the 3rd inst., at his residence in London. He was the youngest son of Mr. Brailesford Bright, the principal partner in the firm of Heron, Bright, McCulloch, & Co., drysalters, in Bishopsgate-street, and head of a well known family in Hallamshire, in the West Riding of Yorkshire. Charles Bright was educated at the Merchant Taylors' School, and very early in life he turned his attention to electricity and chemistry. When a lad of sixteen, he and his two elder brothers joined the service of the Electric Telegraph Company, and Charles, after a short novitiate in the practice room, was sent to Liverpool as junior operating telegraph clerk. Shortly afterwards he was tranferred to Birmingham, and eventually he joined the British Telegraph Company, under Mr. Highton, whilst his brother Edward had meanwhile joined the Magnetic Telegraph Company; and the two brothers brought about the fusion of the two companies, under the title of the British and Irish Magnetic and Telegraph Company. This company became a strong competitor with the Electric Telegraph Company, which was incorporated in 1846, with Mr. John Luis Ricardo, M.P., as chairman, and which original company must be regarded as the parent of all the subsequent telegraph companies. Very early in life Charles Bright was entrusted with erecting telegraph stations and lines in the North of England and in Scotland, and on one occasion he achieved the remarkable feat of laying an underground cable in Manchester in a single night, without causing any interruption to the traffic in the streets. Jointly with his brother Edward, he invented and patented many valuable improvements in telegraphic apparatus, but his greatest achievement was in connection with ocean telegraphy. The late Mr. Crampton, by his cable across the Channel, had shown that signals could be transmitted across the sea; but it was reserved to Charles Bright to conceive the gigantic idea of laying a cable under the Atlantic to join the old world with the new. This was after he had successfully laid the first cable which united Great Britain with Ireland in 1853. He had been experimenting for some time on a system of insulating wires with gutta-percha, and the success with an experimental circuit 2600 miles in length led him and others to the conviction that telegraphic communication with America was possible. The idea found at first but little favour with capitalists in New York and Boston, whom Mr. Field tried to interest in the scheme. Mr. Field came over to England in 1856, and entered into an agreement with Mr. Brett, Mr. Whitehouse, and Mr. Charles Bright, who at that time was the engineer of the Magnetic Telegraph Company. Under this agreement, each of these promoters was mutually bound to push on the undertaking in every possible way, and to share in the ultimate profits to be derived therefrom. Charles Bright and his friends raised the capital necessary for the first Atlantic cable, which was successfully laid by him in 1858, he being then the engineer in chief to the company. He designed the paying out machinery, and the other mechanical appliances required for the submergence of the cable, and associated with him were Sir Samuel Canning, Mr. H. Woodhouse, Mr. H. Clifford, Mr. F. C. Webb, and Sir William Thomson. The two thousand miles of cable required were made in England, and in the laying there were employed four ships lent by the British and the United States Governments. After the great services thus rendered to ocean telegraphy, Mr. Bright was knighted by the Lord Lieutenant of Ireland. Sir Charles Bright was next engaged in submarine telegraphy in the Mediterranean and the Baltic, after which he was summoned in 1864 by the Government of India to complete the telegraphic communication with Europe, which work he accomplished by joining Kurrachee with the northern end of the Persian Gulf. He subsequently superintended the laying of cables between the United States and Cuba, and was also engaged in the erection of telegraph lines between various parts of North and South America. Sir Charles Bright was elected a member of Parliament for Greenwich in 1865, and represented that constituency for several years in the Liberal interest. In 1881 he was appointed by the Foreign Office one of the commissioners to represent Great Britain at the Electrical Exhibition at Paris, and he was afterwards nominated by the French Government an officer of the Legion of Honour. In 1865 he contributed a very important paper to the Institution of Civil Engineers, in which he advocated submarine telegraphy to China and to Australia, and which paper received a Telford medal and premium. He was a member of the Institution of Civil Engineers, the Society of Telegraph Engineers and Electricians, of which he was the president last year, and

THE LATE SIR CHARLES BRIGHT.

he was also a member or fellow of several other learned societies. The above engraving is reproduced from one by Mr. G. B. Black, Regent-street, London, and kindly lent to us by an intimate friend of the deceased gentleman.

Letters to the Editor.

TELEPHONE PATENTS.

To the Editor of "Industries."

Sir,—It having come to the knowledge of the Equitable Telephone Association that the agents of the United Telephone Company are circulating reports to the effect that the Association have not the intention or the means of defending the action for infringement of patents that the United Telephone Company have thought fit to commence against them, the Association ask the favour of your space to give these most unwarranted reports an unqualified contradiction. They also take the opportunity of stating that not only have they the fullest intention of contesting the action to the utmost, but have also every confidence that they will be successful in upholding the freedom of their telephones.

Yours, &c.,
For the Equitable Telephone Association, Limited,
A. Allwinter, Director.

London, 8th May, 1888.

AN APPEAL FOR THE ROYAL VICTORIA HALL.

To the Editor of "Industries."

Sir,—Will you allow me to add a few words to the letter on the above subject which you kindly inserted a fortnight ago? I wish to mention that the proposed memorial, viz., the purchase of the freehold of the Victoria Hall, has the cordial approval of Mr. Samuel Morley's family. It is also desirable to urge that the present opportunity should be seized without delay. It will never recur. Should we fail to raise the necessary sum, £17,000, by August next, the formal arrangement which has been entered into with the landlord would fall through, and at the expiry of the lease in a few years' time the present admirable work of the "Vic" would cease. If we fail in our present effort, there will be no lack of competitors anxious to secure the hall, and work it on ordinary low music hall lines. The Charity Commissioners can only take over the "Vic" after the freehold has been secured. Friends and admirers of Mr. S. Morley, and sympathisers in a work so well tested and so widely useful, are appealed to for a prompt and liberal response.

An influential Memorial Fund Committee is being formed, and subscriptions will be received and duly acknowledged by the Duke of Westminster, hon. treasurer, and Lady Frederick Cavendish, 4, Upper Brook-street, W.; by Miss Emma Cons, hon. sec., Royal Victoria Hall, Waterloo Bridge Road, and by the London and County Bank, Westminster Bridge Road, S.E.

Yours, &c.,
Lucy C. F. Cavendish.

London, 7th May, 1888.

THE LONGRIDGE GUN.

To the Editor of "Industries."

Sir,—A statement having appeared in the daily papers that a 6in. gun constructed from my designs burst at the first round at Woolwich Butts on Thursday, the 26th ult., I desire to contradict such statement, and to explain what really did take place and the cause of the accident. The gun was fired with 34lb. of pebble powder and a projectile of 99lb. The projectile went all right through the screens to the Butts with a velocity of about 1850ft. per second. In order to explain the nature and cause of the accident, which consisted of blowing off the muzzle of the jacket, reference must be made to the accompanying sketches. Fig. 1 represents a general outline of the gun, which weighs 97cwt. Fig. 2 is a longitudinal section at the breech and Fig. 3 a longitudinal section at the muzzle. The gun barrel consisted of a steel tube, 1·6in. thick at the breech and 1·1in. thick at the muzzle. Upon this was the wire coil, 2in. thick at the breech and ⅜in. thick at the muzzle. The tubes and coil were placed inside a cast iron jacket extending from end to end, but did not touch the jacket except at the two ends. Thus it is seen that there was no connection between the tube and the jacket. The tube was therefore free to move longitudinally in the jacket until its front end abutted against the flange of the steel muzzle ring. On the other hand, it was free to expand backwards, a space of about ⅜in. being allowed at A (Fig. 2) between the end of the tube and the breech ring. The tube was kept up to the muzzle ring by six Belville springs placed at A. As the breech plug takes into the breech ring, which again takes into the jacket, it is evident that there can be no backward longitudinal strain on the tube.

The longitudinal strain generally spoken of is a strain between the breech and the trunnions, and it is in respect of resistance to this strain that the wire system of construction is so often said to be defective. The cry has always been that the breech will blow off. There is, however, another longitudinal strain, the importance of which has, I think, never been recognised; and it is this, I believe, which has caused the accident not only to my gun, but to others which have had their muzzle and front part of the chase blown away. This is a forward strain tending to drive the tube forwards in the line of fire. In my gun, as will be seen from the drawings, the whole of this forward strain came direct on to the muzzle ring, and was transmitted from it to the trunnions through the jacket. What happened then was this—the steel tube and coil were driven forward about an inch, and tore asunder the jacket at the places A and B in Fig. 3. The part in front at A followed the projectile to the Butts; the part between A and B, about 1ft. in length, simply moved forward, leaving a space of about ⅛in. wide at B. The steel tube was uninjured, and so was the coil, except that a small portion of it was dragged off the tube and uncoiled by the gun metal hoop C, which was shrunk on to the end of the coil, and was carried away. The wire, however, was simply uncoiled, and was not broken.

How came it that sufficient provision was not made to resist this forward strain? The answer is very simple. I never had the slightest suspicion that a strain of such magnitude would arise. That there was a forward strain I well know; but I had greatly under-estimated its amount.

This strain is due to four distinct causes: (1) The action of the powder pressure upon the difference of area of the obturator and the bore. This in my gun was 1·52in., and as the maximum pressure was 25 tons per square inch, this gives a forward strain of 38 tons. (2) The strain due to the friction of the projectile through the rifling. This in my gun was about 7 tons. (3) The strain arising from the inertia of the mass of the tube and coil recoiling with the gun. This did not exceed 55 tons. (4) The forward force due to the friction of the products of combustion. About this there is great uncertainty. If the question be treated in the usual way for the friction of air through pipes, that is to say, making the friction a function of the density of the fluid and of the square of the velocity, the resulting strain is quite insignificant. In making my calculations for the strength of my gun, I thought I would be quite safe in allowing for a strain of 100 tons from friction. Consequently I made the whole forward strain 38+7+55+100=200 tons, to meet which I gave a sectional area at the weakest part of the jacket of 55·8 sq. in., so that the strain would be $\frac{200}{55·8} = 3·6$ tons per square inch; and as the breaking strain of the metal was ascertained by actual testing to be about 16 tons per square inch, the factor of safety was about 4·5. I am therefore driven to the conclusion that the effect of the friction of the gases is very much greater than anticipated. I think we must consider the action of the gases, or rather of the mixed gaseous and liquid products of combustion, in the same light as that of a body moving upon another with pressure between the surfaces. The nature of these two bodies no doubt affects the co-efficient of friction; but the law that the force to give motion is directly as the surface multiplied by the pressure per inch of surface, must, I think, hold good.

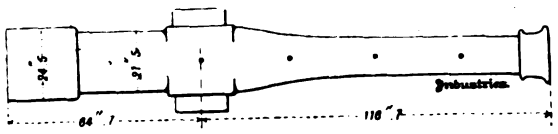

Fig. 1.

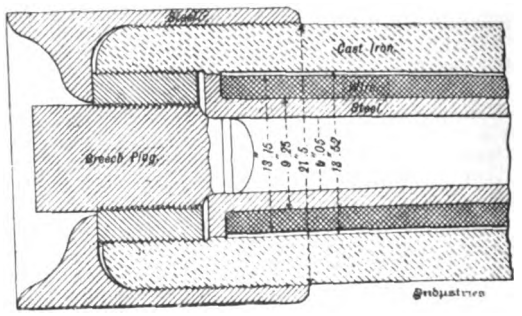

Fig. 2.

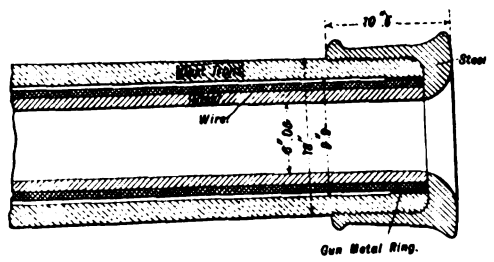

Fig. 3.

Considering the gun from this point of view, I have calculated the effect for two different positions of the projectile: (1) When it has moved 10in. from its original position, at which time the pressure is a maximum. In this case the surface acted on was 836 sq. in., which, multiplied by the pressure, 25 tons, gives 20,900 tons. The velocity of the gases at this time would be zero at the breech, and 636ft. per second against the projectile, or a mean velocity of 318ft. per second; that is to say that we have a body of mixed gas and liquid pressing against the inner surface of the tube with a force of 20,900 tons, and moving at a velocity of 318ft. per second. Making a similar calculation for the moment when the projectile is leaving the muzzle, we get a body of mixed gases and liquid pressing against the tube with a force of 12,160 tons, and moving with a mean velocity of 937ft. per second. Leaving out of account for the present the effect of velocity as increasing the co-efficient of friction, let us see what this would require to be to rupture the jacket.

	Tons.
The strength of the jacket at the period of rupture was ..... $55·8 \times 16 =$	892·8
Deduct the forward strains, exclusive of friction...	100·0
Strain due to friction	792·8

This would give a co-efficient of friction of $\frac{20900}{792·8}$ in the first case, and $\frac{12160}{792·8}$ in the second, or $\frac{1}{26·4}$ and $\frac{1}{15·4}$ respectively. Is there anything improbable in the idea that the co-efficients of friction may not exceed these figures? I think not, especially when we bear in mind the way in which hard steel tubes are scored by the product of combustion. I have very little doubt, then, that the rupture of this jacket was due to this cause.

In the 6in. gun made in Russia from my design, the jacket was arranged differently, and the forward strain was not concentrated at the muzzle end. This gun has fired upwards of six hundred rounds with charges of 39lb. powder and 122lb. projectile, and no accident has occurred. The accident to the gun at Woolwich is due, I freely admit, to an error in the design; but it is an error which may easily be remedied, and which in no way affects the principles of wire gun construction which I have so long advocated. A force whose magnitude was never suspected by me, nor, so far as I know, by anyone else, has manifested itself, and for this I made no sufficient provision.

I believe that the same force greatly contributed to the blowing away the front part of the chase of the "Collingwood" and other guns. In the "Collingwood" gun about 100in. in length was blown off. The surface exposed by this length of the chase at the time of the projectile leaving the muzzle was about 3800 sq. in., and the mean pressure 5 tons. The mean velocity of the products of combustion was about 1500ft. per second, so that there was a pressure of 19,000 tons moving at 1500ft. per second. The friction in this case gave rise to a strain which, no doubt, contributed very largely to the fracture of the chase, if indeed it did not altogether cause it.

Yours, &c.,
Jas. A. Longridge.

THE BOILER EXPLOSIONS ACT, 1882, AND HOW IT IS WORKED.

TO THE EDITOR OF "INDUSTRIES."

SIR,—It is now nearly six years since the Boiler Explosions Act came into force—that is, from 12th July, 1882—and during that time about 257 preliminary inquiries have been carried through, but the first report of a Formal Investigation has only just made its appearance. I asked, in my letter dated the 21st ult., why make a formal investigation at all, after so many years? Perhaps a reply can be given. During that period many explosions have occurred where the responsibility of the owner was of the clearest description, and where a definite expression of opinion would have been invaluable for the prevention of similar occurrences in the future. Nothing, however, was done; and it is only after the attention of the public has been drawn by the most pointed inquiries and remarks in the Press and otherwise, to the neglect of the Board of Trade officials in carrying out the provisions of the Act, that a formal investigation is at last made. The report is now issued; but it carefully avoids giving any decision upon the most important object of the inquiry.

In referring to this very investigation, Mr. Thomas Gray, Assistant-Secretary to the Board of Trade, in "Memoranda prepared for the consideration of the Right Hon. the President of the Board of Trade," and presented to both Houses of Parliament, now issued to the public, complains that "this Act gives very large powers to the Board of Trade and to its inspectors, *but the powers it gives are simply powers of 'inquiry'* after explosion." He refers to this Act in a stronger manner a little further on, remarking, "As I have said, *it is purely an 'Inquiry' Act*'" (the italics are mine), although he is well aware that the whole of the costs and expenses of a formal investigation can be laid upon any careless or culpable owner—a sufficiently formidable fine. If there had been any disposition upon the part of the Board of Trade officials to stamp out boiler explosions, would they not have used the means provided to their hands for so doing? Why has not a formal investigation been held in every case where neglect and mismanagement have been gross, and the costs enforced in each case? If, as I have before pointed out, this course had been taken, boiler explosions would have practically ceased to happen. The mere dread of such an inquiry, and the imposition of such a fine, has produced a degree of care among steam users sufficient to reduce the rate of explosions during the existence of the Act no less than 42 per cent. Instead of this perfectly obvious course being taken, six years have been wasted, and only one formal investigation made. It seems as if the action of the Board of Trade officials was deliberately intended to defeat the object of the Bill; and, by constant misrepresentation of the facts, to show that nothing but governmental inspection of steam boilers would secure safety. And the answer to my question—Why has a formal investigation at last been made?—appears to be simply to attempt to discredit private boiler inspection, and to endeavour to extract evidence from the case in hand sufficient to show that governmental supervision is the only panacea. A very large portion of the report in question (No. 254) is taken up, as you point out, with the prospectus, proposal form, copy of policy and its conditions, and other purely formal documents of the Midland Boiler Inspection and Assurance Company, which, I think, do not appear to bear sufficient relation to the matter before the Commissioners to justify their insertion. Another large portion is devoted to an examination of the chief engineer of the company which insured the boilers, apparently with the view of showing that the premium charged was not sufficient to pay the cost of efficient inspection.

The general tenor of the Commissioners' conclusions goes to show that there was more anxiety to injure boiler inspection as now carried out, and to elicit evidence to its disadvantage, than to arrive at a decision as to where to place responsibility—the real object intended by the Act—and not a very difficult duty when it was shown by the evidence that the boiler was of a dangerous type, thirty-four years of age, during which time it appears to have worked day and night. The Report states that the boiler insurance company's reports showed "clearly that this boiler had been in an unsatisfactory condition for a great number of years, as appears from the continuous leakages, patching, caulking, chipping of seams, and renewals of rivets, which are alluded to therein," and of which the Commissioners say: "The total abandonment of this class of boiler is naturally most desirable, as, both from its design and mode of working, it must always be looked upon with great distrust by all persons conversant with steam boilers. . . . all that can be said in its favour being that it is capable of being easily cleaned both inside and out." In view of these statements, it is much to be regretted the Commissioners have not seen fit to decide the matter, and fix the costs upon the culpable persons. Knowledge of the result would then have spread over the whole kingdom, and both owners, employés, and insurance companies would have reaped the benefit of the lesson. As it is, the interests of all connected with the use of steam power are sacrificed to the extension of official red tape, and to an attempt to erect another State paid office, with all its expensive dependents.

All who are interested in steam power should get and read the "Memoranda" to which I have referred. They will then see in what manner the officials of a department of State consider it proper to deal with a question of vital import to them, and the value and truth of the statements they use for the furtherance of their objects. It is not a cool, candid, and convincing statement of facts such as a State paper of the kind ought to be, but simply a piece of the most careful special pleading, marshalling all the facts, and certain statements that are absolutely false, in regard to boiler insurance and inspection, in the most careful manner, to produce a feeling that compulsory inspection is essential, and that it can only be properly carried out under the care of the Board of Trade. Even the number of explosions is based upon the experience of the last ten years, entirely ignoring the beneficial action of the imperfectly worked Boiler Explosions Act of 1882, and deliberately referring to boiler explosions as "a great and growing evil," in face of the well known and established fact that boiler explosions have been and are rapidly diminishing, both in number and fatality.

Yours, &c.,

Manchester, 5th May, 1888. ECONOMISER.

THE "CRANDALL" TYPE WRITER.

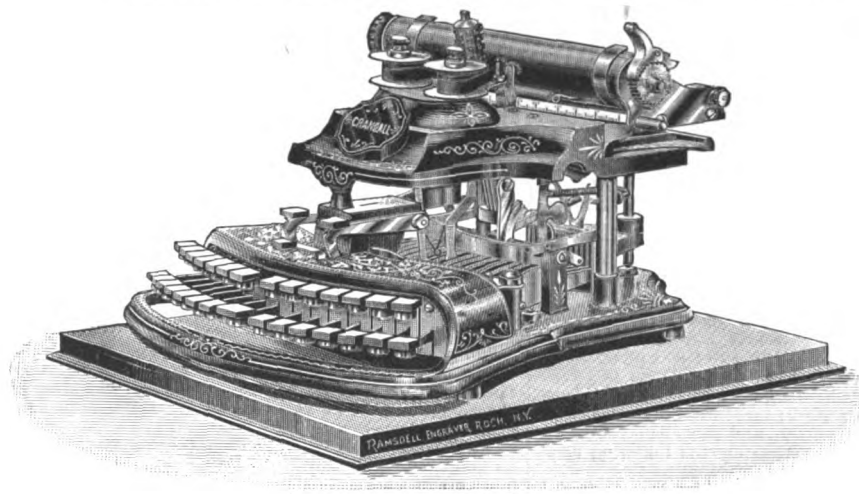

FIG. 1.

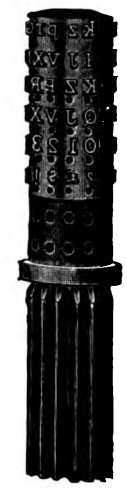

FIG. 2.

THE "CRANDALL" TYPE WRITER.

THE "Crandall" type writer, which we illustrate in Figs. 1 and 2, possesses several distinct advantages over all the similar machines which have hitherto been placed on the market. The chief claims made for it are, that it is a variable spacer, that the distance between the lines may be altered at will, that the writing is always in sight, and that there are only twenty-eight keys, which, however, represent eighty-four different characters. There are no type bars employed, but the letters are all placed upon one solid sleeve, as shown in Fig. 2. The sleeve contains three fields of type, each including small letters, capitals, and figures, punctuation signs, &c.; and the different fields are brought into play by field shifting keys, which are automatically locked down during use. Each character on the sleeve has a corresponding locking hole which closes over a fixed pin, and the sleeve is therefore secured in position until the impression is actually made; this arrangement also prevents the simultaneous depression of two keys. The sleeve can be readily detached from the spindle upon which it works, and can be replaced by another which may carry a different style of type. The ends of the key levers work in inclined grooves cut in a cam at the back of the instrument. This cam actuates a quadrant lever, which is secured to the same spindle as that of the cam, and the teeth on the quadrant lever engage with the pinion on the type sleeve. When a key is depressed the opposite end of the lever rises and causes the cam to move the quadrant lever through a distance which is requisite to bring the corresponding type to the printing position. The letter spacing arrangement adapts the machine for tabulating figures, and for invoicing accounts, besides giving a neater appearance to the printed matter. The machine may be fitted with a paper roller made of hard rubber, which makes it well suited for manifold printing by means of carbon paper. The key board is arranged with the more common letters near the centre, and the space travelled over by the fingers is thus much reduced. The inking is effected by a ribbon, and no handling of this ribbon is necessary, as it moves automatically when the space key is touched; and if desired it can be reeled from one spool to the other at once without the hand being soiled. As a piece of mechanism the Crandall machine is very simple, and on account of there being fewer keys than usual, the number of separate pieces is reduced. Like other instruments of its class, it is made in America; but the manufacturers have an agency at 5, Cross-street, Manchester, Mr. Gardner being the sole agent for the United Kingdom.

NOTES ON AMERICAN FOUNDRY IRON.*

THE iron making resources of the United States of America have so largely increased during the last few years that English iron makers can scarcely afford to look on with indifference while their cousins across the Atlantic are making such rapid progress. Thus, taking the years 1885 and 1886, the production of pig iron in the two countries is returned as follows:—

	1885. Tons.	1886. Tons.
United States	4,529,869	6,365,328
Great Britain	7,415,469	7,009,745

The returns obtained from different sources show some variations, but so far as the purpose of the present paper is concerned, the numbers given may be accepted as correct. It should be mentioned that the quantities for the United States are returned in metric tons of 2000lb.; but even with this allowance the figures are sufficiently startling, for while Great Britain shows a decrease of 406,724 tons, or rather over 5 per cent., the United States on the other hand increased its production by 1,835,459 tons, or rather over 40 per cent.; and this increase was well maintained during 1887, the output last year amounting to no less than 7,187,206 metric tons.

The following notes were suggested by the collection of a set of specimens, prepared by Mr. Keep for the metallurgical department of the Mason College, and intended to be used for teaching purposes. The memoranda accompanying them were not originally intended for publication, or possibly irons might have been selected which would have shown American production in a somewhat more favourable light. But as such a collection is probably the most representative one in this country, and as the information is very complete, it has been thought well to publish it. The irons shown were selected from the collection in the physical laboratory of the Michigan Stove Company, Detroit, of which company Mr. Keep is superintendent. The collection is not intended to show the irons actually used by the Michigan Stove Company, but to illustrate average American foundry iron; these specimens are especially valuable from the fact that in most cases they are samples of the identical irons of which a most complete series of physical tests has been performed, and of which the chemical analysis is known. In a continuation of the present paper Mr. Keep will give details of these tests.

In Great Britain the fuel employed in the blast furnace is almost invariably bituminous coal or coke; but in the United States large quantities of pig iron are produced from anthracite and from charcoal, as shown by the following figures:—

Fuel used.	No. of Furnaces in blast Dec. 31st, 1887.	Production in 1887. Metric tons.
Anthracite	118	2,338,389
Charcoal (Coal and coke.)	74	578,182
Bituminous	147	4,270,635

Michigan produced more charcoal iron in 1887 (213,543 tons) than any other State, while Alabama followed with 95,223 tons. The largest production of any single State is of course that of Pennsylvania, which stands far away ahead with 1,929,777 tons of anthracite iron, 1,742,931 tons made from bituminous fuel, and 11,910 tons from charcoal. The State showing greatest activity in furnace building last year was Alabama, with twenty new furnaces in course of construction. The six States having the largest production stand in the following order:—

	Tons.
Pennsylvania	3,684,618
Ohio	975,539
Illinois	565,453
New York	296,572
Alabama	292,762
Tennessee	250,344
Michigan	213,543

The meaning of these figures will be better understood when we remember that the production of pig iron in the Cleveland district in 1886, is returned as 2,406,276 tons, while South Staffordshire produced only 236,137 tons. Ores of good quality occur throughout extensive districts in the United States. The specimens now shown are intended to illustrate only the irons produced at some of the most important points, and from the principal ore formations. These ore deposits are: (1) The great deposit of magnetic ore beginning on Lake Champlain in Northern New York, and running southward through that State into New Jersey, and still southward to North Carolina; also the brown hematites which accompany this deposit. (2) The great deposit of red fossil ore, running about one hundred miles west of the previous deposit, beginning in Central New York, running through Pennsylvania, and southward to the immense beds of Alabama. This deposit also has contiguous brown ores. (3) The carbonaceous ores of Kentucky and Ohio. (4) The unlimited ore deposits of Lake Superior.

In this brief survey we cannot even speak of numerous other very important deposits, such as those of Missouri, where Pilot Knob and Iron Mountain are of solid ore, or the brown hematites of Tennessee, or the deposits of Wisconsin and other districts. In these instances the ores are chiefly smelted with charcoal. In the case of the Great Southern ore deposit, the ore and coal lie in the same hills, and hence need no transportation; but very

* Paper read by W. J. Keep, C.E., and Thomas Turner, Assoc.R.S.M., on 10th March, 1888, before the South Staffordshire Institute of Iron and Steel Works' Managers.

Digitized by Google

frequently in the United States fuel is transported to considerable distances; in other cases ore is carried, while sometimes ore and fuel are both transported to some intermediate locality. In Eastern Pennsylvania are the great anthracite coal fields, which are reached by a complete system of canals and railways from the Hudson River. In Western Pennsylvania are immense bituminous coal formations, from which excellent coke is made. In Ohio is found block coal, which can be used raw in the blast furnace. In Alabama the best of coking coal occurs with the ore. The chain of great lakes—the St. Lawrence River, Lake Champlain, and the Hudson River, with canals and railways—give facilities for cheap transportation of Lake Superior or Lake Champlain ores to the coke of Western Pennsylvania, to the anthracite of the eastern portion of the same State, or to the coals of Ohio. On the other hand, when necessary, the fuel may be cheaply conveyed to meet the ore.

Poughkeepsie Irons.—This may be taken to illustrate the irons made from the magnetites of Northern and Southern New York, and the brown hematites on the east side of the Hudson; the fuel used is anthracite coal. Poughkeepsie is on the Hudson River; the furnaces are of the older type, 60ft. high with 16ft. boshes; temperature of blast about 1100°F., pressure 8lb. per square inch. The ores employed are used in equal proportions, thus: One-third magnetic ore from Mineville, Essex Co., N.Y. (Lake Champlain ore); one third magnetic ore from Fort Montgomery, Orange Co., Southern N.Y.; one-third brown hematite ores from the Sylvan Lake, Beekman, and Clove Valley, Duchess Co., N.Y. These ores have approximately the following composition:—

	Metallic iron.	Silica.	Phospho-rus.	Oxide of Manganese.
Lake Champlain.....	67·19	1·14	0·84	—
Fort Montgomery...	61·95	7·20	0·24	—
Sylvan Lake.....	51·02	8·51	0·06	trace
Clove Valley.....	49·04	11·95	—	2·71

Beekman resembles Clove, but contains less manganese. The limestone used is taken from the bank of the Hudson River, and the furnace charge yields about 55 per cent. of metallic iron. As illustrating the regular working of this furnace, we may mention that in 1870 Mr. Keep made a memorandum of what he saw charged while spending a day at the works, and this exactly corresponds with the above record of what is used at present. The iron is graded as No. 1 and No. 2 foundry, No. 3 grey forge, and No. 4 mottled. They endeavour to make entirely No. 1 foundry, and other grades come from various changes in furnace working; mottled is seldom made. Analyses of the iron are as follow:—

	Carbon.							
	Total.	Graphitic.	Combined.	Si.	P.	S.	Mn.	Iron.
No. 1 foundry...	4·24	—	—	3·01	0·15	0·05	1·46	90·64
No. 3 grey forge	—	—	—	1·17	1·63	0·15	1·03	91·96
No. 1 foundry...	3·266	3·166	0·100	2·946	1·242	trace	0·189	—
No. 2 foundry...	3·572	3·457	0·115	1·642	1·224	0·035	0·241	—

The first two of these analyses were supplied by the Furnace Company; the two last analyses are of pigs from the same stock pile as that from which the pig was taken for physical tests, to be described in our next paper.

Bushong Iron.—This sample illustrates the production of the Keystone Furnace Company, of Reading, Pa., situated in the heart of the anthracite coal region. The ore mixture consists of one-third brown hematites, obtained near the furnace, with two-thirds of magnetite, principally from New Jersey and Lake Champlain. The iron is graded A1, B1, No. 2 plain, and grey forge. They run on A1, but sometimes get off on lower grades. A pig from the same pile as the pig used for physical tests had the following composition:—

No. 1 Bushong.

Carbon	Total	3·343
	Graphite	2·879
	Combined	0·464
Silicon		1·932
Phosphorus		1·089
Sulphur		0·013
Manganese		0·136

Red Fossil Hematite Irons.—The collection includes two samples intended to illustrate the Great Red Fossil Hematite Formation—one from the Franklin furnaces of Clinton, Oneida County, New York, situated at the extreme northern end of the formation; the other from the Alice furnaces of Birmingham, Alabama, at the extreme southern limit of this ore deposit. The Franklin furnaces use anthracite coal from Pennsylvania. The Alice furnaces are fitted with modern Whitwell stoves, and doubtless work hotter and more rapidly. At both localities two veins of ore occur, one hard and the other soft. At Clinton the soft ore is 1ft. thick, and has been abandoned; the hard ore now used is 2ft. thick. In Alabama both hard and soft ore are used, and occur in beds from 20ft. to 30ft. thick. In most cases the ores are self fluxing. The following are examples of analyses:—

	Clinton soft. (Abandoned.)	Clinton hard. (Used.)	Alabama hard.	Alabama soft.
Metallic iron	30·08	47·50	36·00	50·00
Silica	29·72	11·20	8·00	18·00
Alumina	4·13	4·89	—	—
Lime	8·57	5·53	38·00	—
Manganese	0·31	0·10	trace	trace
Phosphorus	0·67	0·52	0·42	0·70
Sulphur	0·837	0·18	—	—

The analyses of the irons were as follow:—

	No. 2. Franklin.	No. 2. Alice.	No. 1. Rising Fawn.
Carbon Total	3·179	2·963	4·233
Carbon Graphite	3·064	2·742	3·981
Carbon Combined	0·115	0·221	0·252
Silicon	3·014	4·853	1·736
Phosphorus	1·433	0·597	0·828
Sulphur	0·007	0·010	0·018
Manganese	0·168	0·199	0·012

The physical tests of Franklin and Alice iron, to be referred to in a subsequent paper, were made from the same stock pile as the above. This specimen of No. 2 Alice is not a fair sample of the iron usually made. It was sold for, and appeared like, a close No. 2; but both physical and chemical tests show it to be a silvery iron. High temperature, with rapid running, has given high silicon and low carbon, while pure ores have produced a low phosphorus. An analysis is also given of iron from the Rising Fawn furnaces in the north-west corner of Georgia, said to be from a No. 1 pig. This shows more time given for carburisation, hence the production of an open grain. In this case also the silicon is rather low; we should say that the silicon in southern irons would usually run between the extremes above given, generally being nearer the lower than the higher value. The manganese in southern irons is very low, and they show but slight tendency to chill.

Dayton Iron.—The collection of specimens illustrating the production of the Dayton Coal and Iron Company, of Dayton, Tennessee, are of special interest, not merely on account of the completeness of the series exhibited, but also because a complete series of physical and chemical tests are at present being conducted on these irons by Mr. Keep and Mr. H. S. Fleming, and of these tests we hope at a future time to give some account. The samples were selected with special care by Mr. H. S. Fleming (who is now superintendent of Mayville furnaces, Wisconsin) while he was chemist to the Dayton Company. The ore mixture remained the same while the samples were taken, and was much the same as that of the other southern furnace previously mentioned, except that a little brown ore is used. Owing to the needs of their trade at Dayton they make an iron which is slightly higher in phosphorus than most other southern furnaces. The grading is strictly in accordance with the practice of southern furnaces. It will be noticed that the highest grade is No. 2 foundry. This is a peculiarity of southern grading, though a southern No. 2 compares favourably with a No. 1 from many northern furnaces. In the South the furnaces are generally of the modern type, with Whitwell stoves, and run so hot and so rapidly that the grain is a trifle close, and the colour light, when compared with the No. 1 from the older furnaces. An old furnace at Birmingham, Alabama, running more slowly, but using the same ores, makes as dark and open a No. 1 pig as any of the northern iron, and shows a high percentage of carbon. This illustrates the difference caused by various methods of furnace working. In the South there are large beds of red ore now opened, and which will shortly have railway facilities; they yield 59 to 62 per cent. of iron, 6 to 8 per cent. of silica, and 0·25 per cent. of phosphorus, with practically no manganese. It will be seen that this is nearly a Bessemer ore. The southern brown ore contains about 0·68 per cent. of manganese, with 0·27 per cent. of phosphorus. On account of this composition, brown ore is used alone in southern charcoal furnaces to produce a chilling car wheel iron. Southern irons are produced cheaply, and on account of their low price have a considerable influence on the iron market of the United States; hence we have given a somewhat lengthy account of them.

Irons from the Carbonaceous Ores of Ohio.—These ores occur in North-east Kentucky and South-east Ohio, and from a village in the centre of this region, where the ores were first used, they obtain the name of "Hanging Rock Ores." They are also called limestone ores, not because they contain limestone, but because they are found upon a limestone bed rock. These ores produce an iron high in silicon, sometimes as high as 6 per cent., and in the market such irons take the name of "softeners." We have selected two samples of such irons, "Wellston" and "Globe." The samples of Wellston irons are specially interesting. Specimens might have been forwarded of iron from other furnaces, which would have been at least as representative of the district as Wellston irons. But this collection is pretty complete, and was selected by the superintendent of the furnaces, while the ore mixture remained the same. The specimens illustrate the grading and characters of these pigs, and physical tests have been performed on these irons, which will be recorded in our next paper. Special interest is attached to Ohio silicious irons, because for the last twenty-five or thirty years this class of iron has, to a limited extent, served the purposes for which silicon pig is now used in England. Now that the reason for such practice is better understood, the use of silicious iron is spreading in America, and as Ohio softeners are generally low in other impurities, the silicon is thus obtained in such a form that it acts beneficially on the other irons in the foundry mixtures. Silicious irons are not used in all parts of the United States, as eastern irons have generally enough silicon in them already. But in those localities where silicious pigs can be easily obtained, irons can also be easily and cheaply procured, either from the rich Lake Superior ores or from the South, which have hitherto been rather too low in silicon for foundry purposes. With the newer furnaces we may expect the southern irons to be more silicious. The fuel used for the production of much of this high silicon iron of Ohio and Kentucky is a mixture of two-thirds raw coal and one-third coke. An analysis of the coal used at the Wellston furnace is as follows: Water, 11·26 per cent.; volatile matter, 28·96; fixed carbon, 55·59; phosphorus, 0·71; ash, 3·46. The limestone used at the same furnace contained: Carbonate of lime, 93·03 per cent.; silica, 1·51; sulphur, 0·02. The limestone ores, which are of the "Hanging Rock" class, are used roasted; partial analyses of samples are as follow:—

	I.	II.	III.	IV.	V.	VI.
Silica	13·61	15·40	26·22	17·90	25·39	25·89
Alumina	3·00	—	·68	—	—	5·16
Lime	2·90	—	5·24	—	1·25	—
Sulphur	·34	—	·11	—	·73	·082
Phosphorus	—	·36	·18	·29	·17	·488
Metallic iron	39·02	27·00	42·93	49·76	—	41·62

Some old analyses, from another furnace, using a mixture of the identical ores mentioned above, may serve to illustrate the grading and characters of these irons:—

	A1, Grey Foundry.	Strong Mill.	Weak Mill.	Hard Silvery.	No. 4, White.
Graphitic carbon	2·576	—	2·59	—	—
Combined carbon	—	—	·16	—	1·822
Silicon	6·671	2·589	3·924	5·063	6·655
Sulphur	trace	·091	·083	·048	·083
Phosphorus	·503	·798	·547	·755	·643

Manganese not estimated, but probably under 0·5 per cent.

The physical tests of Wellston irons, which will be referred to in our next paper, are very interesting, and it is intended to perform analyses of these samples when opportunity offers. The grade of these silicious irons can of course be varied at will by alterations in the quantity of limestone and of the heat of the furnace. Globe iron is from the same district. The sample exhibited is a No. 1 pig, and has the following composition:—

Carbon	Total	3·154
	Graphitic	2·852
	Combined	·302
Silicon		5·899
Phosphorus		1·100
Sulphur		·02
Manganese		1·00

A pig from the same stock pile was also tested physically, and the results will be given in the second part of this paper.

Irons made from the Ores of Lake Superior.—In concluding this very incomplete account of the foundry irons of the United States, we take samples made from the great ore deposits of Lake Superior. Among the specimens exhibited is a collection of the grades of iron made at the Spearman furnace, situated in Western Pennsylvania, near to the well known Connellsville coke district. The ore used is purchased, and is not confined to a definite mixture, but consists chiefly of hard and soft Lake Superior ore. Many furnaces in this district use some 25 per cent. of Lake Champlain ore to give a more neutral mixture. The specimens shown may be considered to fairly represent the product from the large number of furnaces which are situated near the coke, and which purchase their ore; this is obtained either wholly or in large proportion, as the case may be, from the deposits of Lake Superior. There is also a very interesting collection of examples of iron made from Lake Superior ores and smelted with charcoal at the Gaylord furnace, Detroit, Michigan. Several of these specimens have been analysed by Mr. Fleming, and his results are as follow:—

	Silicon.	Phosphorus.	Sulphur.	Manganese.	Iron.
Gaylord No. 2 foundry	1·570	0·240	0·041	—	94·283
" No. 3 foundry	0·800	0·144	0·056	—	94·688
" White	0·186	0 263	—	0·092	—

It will be seen that these irons are of exceptional purity, and may be considered above the average for foundry purposes. They are used chiefly for special purposes, such as the manufacture of car wheels. At a future time we may be able to publish details of physical tests of these specimens.

In a continuation of the present paper (which we hope to publish in an early issue) an account will be given, under the head of "Keep's Tests for Foundry Iron," of the physical characters of the pig irons mentioned in this preliminary portion of the subject.

GLAZES FOR PORCELAIN WARE.

MM. Lauth and Dutailly have recently communicated to the French Chemical Society the results of their investigations on the red glazes which are produced on porcelain by means of copper and its salts. The colour produced in this manner is of a much more permanent nature and of a far superior tint than that which is obtained when oxide of iron is used for the same purpose. This red colour, when used for decorative work on ancient porcelain, is often accompanied with a blue colouring matter beneath the surface of the glaze. It appears that the secret attached to the production of these colours was known only to the Chinese until recently, and that the red, known as Tsi-houng, or *sang de bœuf*, could not be imitated by the French at the porcelain manufactory at Sévres. In 1852, MM. Ebelmen and Salvetat endeavoured to reproduce these copper colours in France by making careful analyses of fragments of Chinese porcelain coloured in this manner, and then imitating, in the composition of the glaze and clay employed, the Chinese specimens. The results of these earlier experiments are now in the ceramic museum at Sévres, and are the first examples of the kind produced in Europe. Other French chemists have since then attempted to improve on the first trials, and the problem has also been attacked by H. Seger, of the Berlin Porzellan-Fabrik, and by H. Bünzli, at Krummnus, in Austria. MM. Lauth and Dutailly have established by their experiments that the maximum temperature which the Chinese red glazes can stand without losing their colour approaches to that used for baking the new Sévres porcelain. By successively associating all the compounds capable of entering into the formation of a colourless glaze with oxide of copper, they have come to the following conclusions: That in the same series of glazes, those which produce the finest red colour with copper compounds have the greatest amount of silica present, and that in a series of glazes of approximately the same degree of acidity, the best results are obtained when there is a large proportion of alkalies and a small percentage of alumina. They have further noticed that if the alkaline metals be increased in relation to the alkaline earths present, a finer red is produced, but at the same time the liability to break is increased. By employing boracic acid or borates this inconvenience may, in some measure, be prevented. Lime, magnesia, various fluorides, and lead and iron oxides have also been tried; but the results obtained by their use have not proved satisfactory. A very good red glaze can be produced when zinc oxide and baryta are the bases present in the glaze. The copper

Digitized by Google

can be introduced into the glaze in different ways. Oxalate of copper, simply mixed and not fused with the melt, gives good results; but if previously fused with the glaze, very satisfactory colours are produced. The quantity of copper salt employed depends on the time required for baking the porcelain, and also on the temperature of the furnace. Five per cent. is the quantity which is recommended as the most suitable to use, and the addition of a small quantity of tin oxide is advantageous. The glaze which has given the best results has the following composition:—

Pegmatite	31·17
Sand	36·37
Fused borax	12·98
Dry carbonate of soda	4·76
Barium carbonate	10·39
Zinc oxide	4·33

Corresponding to:—

Silica	61·02
Alumina	5·85
Alkaline oxides	10·72
Baryta	8·42
Zinc oxide	4·51
Boric acid	9·48

This glaze has a degree of acidity represented by the number 5·39, that of the French glaze, No. 1, being 5·14. The bases are in the proportion which corresponds to the formula:—

$$Al_2O_3, 3\ NaKO, BaO, ZnO.$$

By using this glaze with a similar one containing lime, M. Lauth and Dutailly have succeeded in obtaining a great variety of colours on the same material, and in producing some effects on porcelain which have not hitherto been achieved.

Notes.

WINDOW GLASS.

British manufacturers of window glass appear to be neglecting a market for their goods, as a foreign office report from Swatow states that all the window glass sold in the ports of China, and even in Hong-Kong, is of Belgian or German origin, and of a most inferior description, and that it is impossible to procure a piece of glass of sufficiently good quality for a picture. The Chinese paper windows have already largely disappeared in the ports, and the British Consul describes the Chinese made glass as "so inferior in quality that it has no chance even against its present atrocious foreign substitute." China should, therefore, eventually afford a good market for British glass.

OILING THE WAVES.

We published last week an article entitled "The Effect of Oil on Waves," and in connection with this subject we have received from Messrs. A. B. Fleming & Co., Caroline Park, Edinburgh, a letter which has been addressed by J. C. Beckett, master to the Superintendent of Pilotage, Liverpool. Mr. Beckett states: "I experimented with a five-gallon drum of oil on the 20th March last, off Point Lynas; wind, E.N.E. force 7, with heavy sea running and broken water. The following are the results, viz.: First boat hove to, end on to sea, head reaching about one mile per hour; the sea for about 50ft. around the boat was literally smooth, that is sufficiently smooth to launch or lower a boat without any danger. I then ran the boat before the sea, and with the oil going astern, I saw that the sea could not break over the stern of the vessel, as the sea, after coming in contact with the oil, became immediately smooth. I then ran towards No. 2 pilot boat, and saw that the sea was breaking over her bows in heavy spray, while we were in perfectly smooth water. There were several pilots on deck to testify to the above statement. The oil continued to run out for forty minutes."

ELECTRIC LIGHTING AT THE ITALIAN EXHIBITION.

The Italian Exhibition, which will be opened to-morrow, is lighted by three hundred arcs of 2000 c.p. nominal, distributed throughout the buildings and grounds, and one hundred glow lamps, fixed in the Welcome Club. The installation is on the Thomson-Houston system, and has been laid down by Messrs. Laing, Wharton, & Down, of 82, New Bond-street, London. There are ten arc dynamos, each of thirty-five lamps capacity, and one glow lamp dynamo, of one hundred lamps capacity. All the dynamos are driven from one counter shaft, running at 250 revolutions per minute, and provided with 4ft. 6in. pulleys, the pulleys on the dynamos being 16in., and the speed 820 revolutions. Motive power is supplied by Davey-Paxman boilers and engines, there being three locomotive boilers, each of 100 actual horse power, and one compound undertype combined engine and boiler of 40 nominal horse power. In addition, there is fixed a compound engine of the girder type, of 40 nominal horse power, running at one hundred revolutions per minute, and driving from an 8ft. 6in. fly wheel on to a 3ft. 6in. pulley on the counter shaft. There are also two Windsor engines of the inverted compound type, each of 30 nominal horse power, running at 180 revolutions, and driving from a 5ft. 6in. fly wheel on to a 4ft. pulley on the counter shaft.

RICE CULTIVATION IN BRITISH GUIANA.

M. Gilzeau, in a paper contributed to *Timehri*, the journal of the Royal Agricultural and Commercial Society of British Guiana, considers the cultivation of rice to be one of the most promising industries of the colony. Some twenty-two years ago about twenty acres of rice were grown in British Guiana, but difficulties were experienced in cleaning and preparing the grain for the market. At first loss of crops from floods and drought was experienced; but by means of irrigation excellent crops of rice have since been obtained, and on some estates three crops a year have been raised; and the land, with no rotation of crops nor rest, shows no falling off in the yield. When no rent is paid for the land, a considerable profit has attended the growing of this crop in the colony, and even when a small rent has to be paid there is a considerable margin for profit. At present the cleaning is done by the primitive "stamper pot," but it is hoped that the colony will be in a position to keep a mill of its own running before long. The rice grown in British Guiana resembles the finest samples of Java and Italian rice, and cannot be grown in the great rice producing parts of India. M. Gilzeau points out that the development of this industry will cause employment to the gangs in the slack season, as at present the principal labour required is in reaping canes—an operation which lasts only for a few months.

ALUMINIUM BRONZE.

Aluminium bronze is of daily growing importance in the eyes of American military experts. A writer in the current number of the Journal of the United States Cavalry Association, points out that this alloy might with advantage be used in the construction of breast plates. There is no doubt that the days of defensive armour are by no means past; the advantage of the cuirass was shown in the cavalry combats of the Franco-German war, and the far range of the modern rifle may render it every day more desirable that some attempt should be made to counteract its deadliness. Gun shields also will sooner or later become necessary, and it may be that in this alloy will be found the solution of the question—how to protect light artillery and cavalry without sacrificing mobility. Captain W. Hall, the writer above referred to, gives an interesting comparison, which was made by his Government, between the average of 130 specimens of accepted gun steel, and an alloy of 90 parts copper and 10 aluminium. This comparison is as follows:—

	Aluminium alloy. Lbs. per square inch.	Gun steel. Lbs. per square inch.
Tensile strength	111,400	96,150
Probable elastic limit	84,000	51,611

It is considered that modern methods of working aluminium, especially by aid of the electric furnace, will so reduce the price, that it will come into general use for many purposes, and already various grades of alloys are quoted in the United States as commercial articles, varying in price from 16c. to 45c. a pound.

AN AMERICAN MILITARY ENGINEER'S CRITICISM ON THE "DYNAMITE GUN."

At a recent meeting of the Military Service Institution, United States, General H. L. Abbot, of the Corps of Engineers, criticised this weapon adversely. He did not believe in the practical value of the pneumatic gun in coast defence, because its short range restricted its fire to the area already obstructed by submarine mines, and the defenders cannot afford to make every shot that misses the enemy a countermine to destroy the mines, and thus open a route for his passage. The mines are indispensable, because steam vessels can force their way through any unobstructed channel under cover of darkness, whether the projectiles thrown at them contain gunpowder or dynamite; and it would be inadvisable to introduce a new weapon that directly antagonises another of prime importance, which it cannot replace. If it be suggested that the use of the "aërial torpedo" may be restricted to the period of the siege, when, the submarine mines having been destroyed by the enemy, he is ready to attempt to pass the forts, we must remember the high trajectory of the weapon. Vertical fire is not effective against a rapidly moving target, such as would be presented by the enemy's ships when once the channel is opened. For the dynamite gun was claimed the exclusive ability to throw detonating substances with safety; but it was stated on good authority that mortar shells charged with 110lb. of wet gun cotton were fired successfully in Germany, and improvements in the manufacture of such substances pointed to their early use even in guns. The pneumatic gun was more useful in the navy than the army: as a counterminer to destroy submarine mines, it might have a value, although without absolute proof he would be loth to believe that it could do more than moderately assist in the opening of any known and well defined channel from four to six miles long, without which no armoured ship could safely pass the forts. Even then it would be a serious matter to manœuvre an unarmed floating magazine, containing many tons of dynamite, under the fire of modern high power guns, mounted on land at a range of one or two miles.

THE FUMAT SAFETY LAMP.

This new safety lamp, which has been devised by M. Fumat, the chief engineer in the French mines of the Grand' Combe, gives a good light, and is not extinguished when it is violently shaken or held in an inclined position, and does not cause an explosion when placed in a strong current of air charged with fire damp. When lowered into an explosive mixture of air and fire damp, an explosion takes place within the lamp as soon as the flame comes in contact with the explosive mixture; but by the ingenious construction of the protecting network, the heat generated is prevented from raising the temperature of the outer metallic portions of the lamp. Oil is used in this lamp, and it has been used for some time in the mines at the Grand' Combe, and by the firemen in Paris, with very satisfactory results. MM. Mallard and Le Châtelier have also put the lamp to many severe tests in their laboratory, and have found that it fulfils all the conditions of safety which the inventor claims for it. Its cheapness, coupled with these properties, will, it is hoped, cause it to be used in other mines, where lamps of more expensive construction have hitherto been employed.

THE ELECTRIC LIGHT IN THE SUEZ CANAL.

The number of ships navigating the Suez Canal at night with the electric light shows a rapid increase since the new regulations came into force on the 1st March last year. Consul Burrell, of Port Said, gives the following table showing the number of vessels with the electric light passing through the canal in each month last year:—

January	13
February	12
March	15
April	19
May	19
June	25
July	27
August	35
September	45
October	49
November	63
December	73
Total	395

The average time of the transit of the canal in 1887 is given as 33 hours 58 minutes, as compared with 36 hours in 1886. The shortest time taken by an ordinary steamer with the electric light for night navigation was 15 hours 5 minutes. A still faster passage was made by Mr. Gordon Bennett's steam yacht "Namouna," which, being allowed to steam at greater speed than larger vessels, only took 13 hours and 53 minutes from Port Said to Suez.

COTTON GOODS IN CHINA.

The British Consul at Swatow, in reporting on the trade of that port during last year, states that all branches of the cotton trade show an improvement on 1886, the advance being most marked in white shirtings and T-cloths. The figures, however, in most cases were not as high as in 1885, and considerable stocks were left in hand at the close of the year. The Consul states that some British manufacturers have attempted to make imitations of native cloths, but the results have so far not been encouraging. He suggests that manufacturers should give their attention to maintaining their supremacy in the line in which they have already obtained a footing in the Chinese markets, and that they should at the same time try and produce an article as cheap and as durable as the native Chinese cloth. He says that it need not be a close imitation, but should be of narrow width, and that a careful study should be made of the tariffs under the Tientsin treaty, in order to ascertain the dimensions on which the Customs duties would be least. No sizing or filling should be used. Owing to its being much cheaper, cotton yarn from Bombay prevents English yarn from finding a market at Swatow. Our Consul at Pakhoi states that last year's imports of cotton goods at that port were of the value of £445,000, or twice as much as in 1886. The imports of cotton yarn, all of which was derived from Bombay, have also doubled. At Kiungchow cotton piece goods and T-cloths show a small increase over the imports in 1886, but are not equal to those in 1885.

Patent Record.

Compiled from "The Official Journal of the Patent Office," by W. E. Heys, *70, Market-street, Manchester.*

APPLICATIONS FOR PATENTS.

(The names in italics within parentheses are those of Communicators of Inventions.)

ENGINEERING.

27th April, 1888.

6232. Stevenson, J. ..... Knitting machines.
6233. Gimson, J., & others..... Machines for skiving and trimming leather.
6236. Martin, E..... Manufacture of cloth.
6246. Walker & Leek ..... Wringing sized or dyed yarns.
6252. Jefferies, E. A. ..... Locomotive, marine, and other engines.
6259. Chartres, A. H. ..... Equilibrium valve for steam engines.
6262. Knowles, W..... Mules.
6263. Entwisle, A. J..... Steam heated drying cylinders.
6266. Haddan, H. J. ..... Tube expanders (*Trubel*).
6271. Lloyd, S. ..... Machinery for transferring boats from one level to another on canals and rivers.
6274. Rothschild, S. A. ..... Means for enabling tramway vehicles to automatically operate points.
6277. Clarke & Mawby..... Manufacture of hoisery.

28th April, 1888.

6286. Anderson, A. ..... Sewing machines (*Singer Manufacturing Co.*)
6288. Foster, H..... Internal flues and fire boxes of steam boilers.
6292. Patterson, W..... Prevention of overwinding in mines.
6297. Kenyon, W., & others... Friction clutches.
6301. Hollingworth, E..... Jacquard looms.
6306. South & Bursch ..... Couplings for railway cars.
6312. Walsh & Wild..... Sizing or taping machines.
6320. Gresham, J..... Vacuum brake.
6326. Greenway, A. G..... Manufacture of iron.
6328. Volonté, C. ..... Pulveriser.
6334. Leigh, H. H..... Machines for making nails (*Liefmann*).
6335. Leigh, H. H..... Machine for jumping the heads of nails (*Liefmann*).
6340. Imray, J. ..... Screening drums for sizing coal (*Bartsch*).
6342. Morawetz, G. V..... Fastening railway rails.
6345. Burley, W. ..... Examination of vessels' hulls while afloat.
6347. Chabeau, A..... Alarm signalling apparatus and break operator for use on railway trains.
6351. Dutton, S. T. ..... Signalling on railways.
6352. Yaryan, H. T..... Purification of water in steam boilers.

30th April, 1888.

6359. Wright, E. ..... Transmitting and controlling motion in machines and hand tools.
6365. Binns & Skinner..... Machines for combing wool.
6367. Robson, R. F. ..... Communicating motion from a prime mover.
6381. Greenwood, A. ..... Ring spinning frames.
6392. Thompson, W. P..... Controlling the draught of furnaces (*Van Hecke & Laurent*).
6396. Wise, W. L. ..... Embroidery machines (*Frey and Kœnig*).
6398. O'Donnell, J. P..... Railway signalling.
6399. Howard & Bousfield.. Railway sleepers and chairs.
6401. Molesworth, T. C..... Bottle washing machinery.
6403. Roe & Kent..... Jacquard apparatus.
6413. Chatwood, S., & others.. Safes and strong rooms.

1st May, 1888.

6419. Burrell, F. J..... Governing steam engines.
6426. Biddiscombe, F. ..... Improved railway line connector.
6427. Masterton, J. F..... Steamboat pier signalling.
6430. George, J. ..... Driving clutch.
6434. McGrady, H. ..... Type writers (*Crandall*).
6435. Martin-Epton, W. ..... Lubricator for solid oils.
6438. Groves, F. ..... Coupling railway carriages.
6441. Clarke, J. K. ..... Lubricators for loose pulleys.
6442. Illingworth, J. ..... Pipes, gas retorts, and other hollow articles.
6443. Sutro, L. ..... Knitting machines.
6445. Granville, B..... Type writing machines.
6449. Higginson, A. ..... Apparatus for directing the flow of fluids.
6464. Whibley, E..... Band sawing and fret sawing machines.
6465. Hale, J. M. ..... Propellers.
6468. Kortynski, K. von ..... Gas engines.
6473. Thompson, W. P..... Screw vessels (*Sylven*).
6475. Boult, A. J. ..... Valves for steam engines (*Tolton*).
6484. Davy, C..... Blowing engine.
6485. Wilkins, F. ..... Type writing apparatus.
6487. Redfern, G. F. ..... Centrifugal apparatus (*Hansen*).
6490. Wright, R. ..... Hydraulic engines.
6493. Tasker, S. P. M. ..... Rolling mills.
6494. Tasker, S. P. M. ..... Roller mandrels.
6505. Cannon & Addison..... Artificial draught.

2nd May, 1888.

6509. Bodden, W. ..... Ring spinning and doubling frames (*McMullan.*)
6510. Smith, S. ..... Moulding machines.
6520. Hutchinson, R. R. ..... Armour clad trains.
6529. Wood, C. ..... Gig mills.
6534. Bottomley & Day ..... Brake apparatus.
6535. Stott, W. ..... Winding frames.
6536. Rhodes & Bywater ... Trip motion for Corliss valves.
6540. Adair, W..... Mills for grinding grain.
6542. Thompson, C. ..... Looms.
6543. Green, J. ..... Self righting boats.
6544. Moore, J. ..... Coupling railway vehicles.
6546. Corcoran, B. ..... Millstone trammel.
6549. Holleman, F. A. ..... Railway brakes.
6565. Brigham, R. ..... Lubricators.
6570. Brasier, E. ..... Apparatus for washing, bleaching, drying, and softening fibrous and textile materials.
6573. Wrigley, J. ..... Steam traps.
6574. Daniels, W. H..... Keels for ships' boats.
6581. Dry, J. R. ..... Operating on jute and rhea canes.

3rd May, 1888.

6584. Maund & Millechamp. Self acting field clock gun.
6589. Lynch, G. ..... Machinery for printing surfaces of cardboard while it is being cut and scored for making boxes.
6594. Sleading, R..... Lubricating machinery.
6596. Butler, E..... Propulsion of tram cars by means of internal combustion engines.
6597. Shaw & Harcourt..... Clutches, couplings, and brakes.
6599. McConnel & Higginson Grinding the flats of revolving flat carding engines.
6602. Simons, J. F. N. B. ..... Manufacture of pipes.
6603. Blamires, T. H. ..... Scribbling carding engines and condenser carding engines.
6604. Smith & Ambler..... Machinery for doubling yarn.
6617. Allen, J. B..... Printing from strips of electrotype, and fixing the same upon printing blocks.
6620. Templeman, G. ..... Knitting machinery.
6621. McEuen, C. H..... Steamboat construction (*Selfe and Selfe*).
6622. Laszgallner & Nöhring Draught regulators in locomotive furnaces.
6631. Mégy, L. ..... Hoisting apparatus.
6637. Robinson, H. E. ..... Locking the fish plate bolts of railways.
6638. Gordon, J. ..... Drill guns.

ELECTRICITY.

27th April, 1888.

6237. Millar, A..... Electric batteries.
6270. Jobson, H. C..... Fixing insulators to telegraph poles.

28th April, 1888.

6314. Hall, J. P..... Dynamo-electric machines.
6322. D'Humy, P. R. de F..... Galvanic batteries.
6344. Davies, W..... Means of conveying telegraph wires.

30th April, 1888.

6373. Dill, L..... Electric batteries.
6390. Mackie & Sharp..... Electrical switches.
6400. Dingle, W. H..... Electrical signalling apparatus.

1st May, 1888.

6416. Hoppe & Hoppe ..... Galvanic batteries.
6481. Lake, H. H. ..... Electrical transmission of power (*Tesla*).
6502. Lake, H. H. ..... Generation and distribution of electric currents (*Tesla*).

2nd May, 1888.

6578. Johnson, J. Y..... Incandescent electric lamps (*Philippart*).

3rd May, 1888.

6613. Miller, S..... Automatic resistance for electric light circuits.
6614. Craven, E. G. ..... Electrical illumination of clock dials.
6627. Tabourin, G. A..... Combined generator of electricity and electric lamp.

CHEMISTRY.

27th April, 1888.

6248. Dawson & Hirsch ..... Purification of nitric acid.

28th April, 1888.

6307. Ruffle, J..... Utilisation of the exit gases from vitriol chambers.
6319. Johnson, J. Y..... Dye stuffs (*The Farbenfabriken vormals Friedrich Bayer & Co.*)

30th April, 1888.

6407. Lake, H. H. ..... Disinfectants (*Shaw*).

1st May, 1888.

6428. Taylor, J..... Soft soap.
6460. Lake, H. H. ..... Aluminium (*Seymour*).
6470. Woods, J. E. T. ..... Recovery of refuse metals.
6478. Thompson, W. P..... Preventing the decomposition of organic substances (*Moro*).
6491. Levick, H..... Tanning.
6495. Pitt, S. ..... Manufacture of metallic oxides (*Bradley*).

2nd May, 1888.

6508. Scaife, J. ..... Utilising waste gums.
6513. Thwaite, B. H. ..... Converting soluble sulphides and sulphates into carbonates.

3rd May, 1888.

6634. Schreiter, M. J..... Refining camphor.

MISCELLANEOUS.

10838A. Rawson & White..... Springs. (This Application having been originally included in No. 10838, dated 6th August, 1887, takes, under Patents Rule 23, that date.)

27th April, 1888.

6230. Chambers, C..... Cork drawing machines.
6235. Bailey, I. ..... Securing cams on to screw shafts employed in gill boxes.
6243. Howat, A..... Rivets used for locking miners' safety lamps.
6249. Okes, J. C. R. ..... Valves and valve boxes.
6256. Clarke, W. R. ..... Torrefying grain.
6260. Forrest, J. C. ..... Haulage clip.
6261. Sellars, J. C..... Cement.
6267. Earle, E. J. V..... Manufacture of boots.
6269. Jutson & Poupard..... Shoes for horses.
6275. Ollendorff, B. ..... Blocks for holding zinc plates for printing purposes.
6276. Whitehouse, D. ..... Manufacture of tin and terne plate.
6280. Bonneville, L..... Explosive compounds.
6282. Berend, O. A..... Filtering water.

28th April, 1888.

6284. Hopewell, H. ..... Superheating rooms.
6285. Born, P..... Apparatus for producing jets of spray (*Schmid*).

9468. Shillito, T. R. ..... Red azo colour (*Geigy*).
9873. Parnell & Simpson ... Sulphuretted hydrogen.

MISCELLANEOUS.

5th May, 1888.

6875. Wood, A. M. ..... Treatment of india-rubber, gutta-percha, and analogous gums.
7598. Vallet, L. ..... Internally stoppered bottles.
7874. Claret, J. J. ..... Lock nuts.
7990. Imray, J. ..... Incandescence gas burners (*Clamond*).
8626. Massey-Mainwaring, W. F. B. ..... Safety lamps.
8714. Reynolds, W. J. ..... Mariners' liquid compasses.
8738. Reeve, S. ..... Warming and ventilating apartments.
9091. Golding, W. ..... Velocipedes.
9169. Patterson, E. ..... Miners' safety lamps.
9224. Jackson, I. ..... Tape fastener.
9240. Singleton, T. ..... Stoppering bottles.
9254. Asbury, J. ..... Velocipedes.
9268. Smith, F. A. ..... Manufacture of ice.
9521. Johnson & Hutchinson Filter presses.
9592. Tweedie & Muirhead.. Cartridges.
9717. Ducretet, E. ..... Filtering oil.
9832. Shepherd, G. ..... Apparatus for drying air.
9847. Wootton, W. ..... Stoppers for bottles.
10130. Schoembs, H. ..... Preparing zincographic printing plates.
10244. Rigby, J. S. ..... Cement.
11735. Baldwin, J. ..... Pressing paper whilst in the process of manufacture.
14474. Weatherill, W. P. W. Springs.
15283. Fielden & Slater ..... Shuttle guards for looms.
16833. Stevens, B. W. ..... Line throwing with a gun.
179. Sinnatt, W. H. ..... Stoppers for bottles.
1273. Morisseau, A. ..... Boring tools.
2478. Wilding, R. ..... Rollers for spinning machines.
2532. Singer & Judell..... Cleansing wool.
3006. Lillie, S. M. ..... Evaporating apparatus.
3140. Poole, W. ..... Cinder sifters.
3533. Dronier, P. ..... Magnesium lamps.
4099. Newton, J. H. ..... Refrigerating machines.
4211. Rivière, V. ..... Treating tanned hides and skins.
4405. Higgins, C. M. ..... Bottle stoppers.
4484. Wren, J. E. ..... Manufacture of gas.
4632. Cawkwell, H. A. ..... Manufacture of tiles.
4703. Haddan, H. J. ..... Fasteners for driving belts (*Gingras*).
4747. Lemaire, V. D. A. ..... Hinges.
4761. Adnet, P. ..... Pitch forks.
4822. Newton, P. A. ..... Printing type (*McClure & Virian*).
4827. Bade, C. ..... Extinguishing fire.
5035. Schmidt, C. A. G. ..... Dyeing and bleaching textile fabrics.

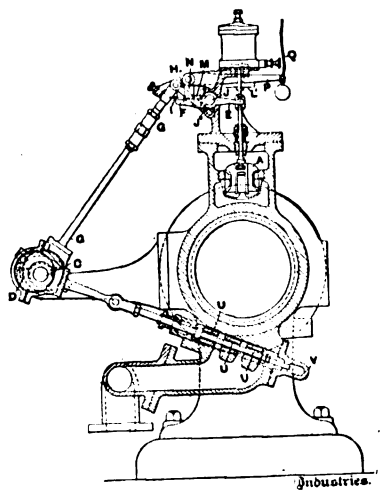
ABSTRACTS OF BRITISH PATENT SPECIFICATIONS.

Compiled from the Published Specifications by **W. E. Heys, 70, Market-street, Manchester.**

ENGINEERING.



Shaping Metal Tubes.—*A. Paterson, Mackeesport, Pennsylvania.*—The machine described in the specification is intended for giving special shapes to metal tubes. The roll boxes C slide in vertical slots in the housings A and B, and form bearings for the rolls D. The nipple rolls are supported by the carriers R, which slide in horizontal slots in the rear housing A. The

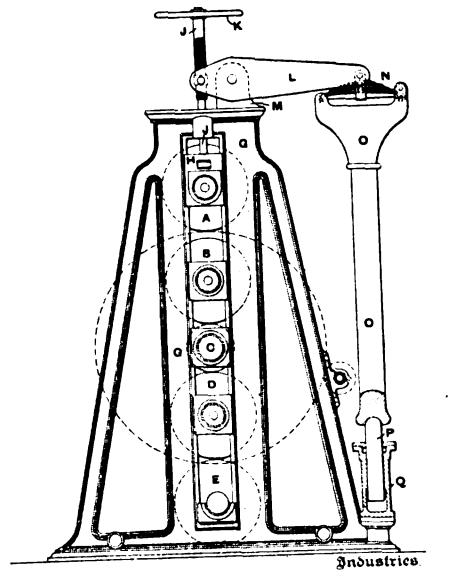
chuck F revolves freely in the bearing E. Motion is transmitted from the driving shaft G to the rolls D through the worm gear J K. The two shafts H are on different sides of G, and are driven by one worm on the shaft G. The vertical screws M are driven by the worm wheels N, and serve to raise and lower the rolls D. The shaft L on which these worm wheels are fixed is driven from the main shaft through the gear wheels P O. A clutch Q is interposed in order to throw either of the spur wheels into gear. The rack T in the rear face of each nipple roll carrier gears with the pinion U on the upright screws M. While the vertical screws are opening and closing the main rolls, the pinions U are simultaneously opening and closing the nippling rolls. The different means for causing these two movements causes the opening and closing of the nippling rolls to take place quicker than the main rolls. Nine claims are made.—No. 17119. December 13th, 1887. 8*d*.

Digitized by Google

VALVE GEAR.—*J. Richardson & B. R. Rowland, Lincoln.*—The accompanying figure shows part of the mechanism which has been designed by the inventors for working the trip valve gear of Corliss engines. The Cornish double beat valves A admit the steam, and these and the exhaust valves U are operated by the eccentrics D on the shaft C. The valves A are lifted by levers E, whose outer ends F are depressed by the appliance I. The upper ends of the eccentric rods G are carried by link rods H, which can describe an arc of a circle; when the trippers I descend, the link rods move further from the centre of the lever E, until they release themselves from the end F. The valves A then fall instantly upon their seats. The pin J is made of a round rod, and is movable horizontally in its housings. The fulcrum J is coupled by small connecting rods M to the lever N, by which a

horizontal motion is imparted to the fulcrum by the varying positions of the lever P. The lever P is connected with the governor of the engine. The end F of the tripping lever is caused to approach and recede from the tripper I, and the point of cut-off is thus varied. The lever P may have a cord Q attached to it, and the cord is carried all round the mill, so that in case of accident the engine can be stopped. The exhaust valves U are of the triple ported pattern, and their working faces are those farthest removed from the cylinder. They are thus always pressed towards the face by the pressure of the steam inside the cylinder. The valves can be easily examined or removed for repairs, by simply unfastening the covers V. Four claims are made for the inlet valve gear, and for the exhaust valve as described, and for another modification consisting of an oscillating exhaust valve.—No. 3744. March 11th, 1887. 11*d*.

HOLDING AND GUIDING TWIST DRILLS.—*W. J. Griffiths, Greenwich.*—The appliance designed by the inventor for holding and guiding twist drills consists of three parts, viz., a base plate, on which is cast a vertical socket; a casting, having in it a horizontal cylindrical socket, and supported by a pivot that fits the vertical socket; and a chuck for holding the drill that is to be ground. The forward part of the outside casing of the chuck is cylindrical in form, and fits into the horizontal socket. The chuck is constructed with three wedge-shaped pieces, which enter from the hinder end, and approach each other as they go forward; the wedges are constructed with projecting edges at their hinder ends, and are so arranged that when one of them is moved forward, it carries the other two with it. It is necessary to give the wedges a considerable taper, and in order to hold the different sized drills securely, a screw is placed in a direction parallel with the outside of the wedge which pushes in the other two; a nut on the screw prevents the three wedges from moving back. In order to obtain the necessary rotation of the drill, a cam is fixed at about the middle of the length of the outside casing of the chuck; the shape of this cam is such that when the chuck is turned through an angle of 90° in the horizontal socket, while the cam is kept in contact with a fixed guide bar, the inclination of the axis of the chuck and the drill is altered through an angle of 10°. The drawing back movement is regulated by means of a second cam, which is held in contact with the end of a screw; this screw passes through a nut fixed in a slot in the piece which carries the horizontal socket. The cam has a helical surface, which has at its greatest radial distance from the axis of the chuck a suitable pitch for giving the drawback necessary for the largest twist drill; the pitch will be gradually reduced as the radial distance is diminished, until it vanishes just outside the cylindrical end of the chuck. The drawing back motion can consequently be made greater or less according to the position in which the nut is fixed in the slot; a scale is marked on the side of the slot, and by its means the nut can be set to the required position. Two claims are made for the chuck, and for the combination of the segmental cams for regulating the movements of the drills.—No. 17677. December 23rd, 1887. 8*d*.

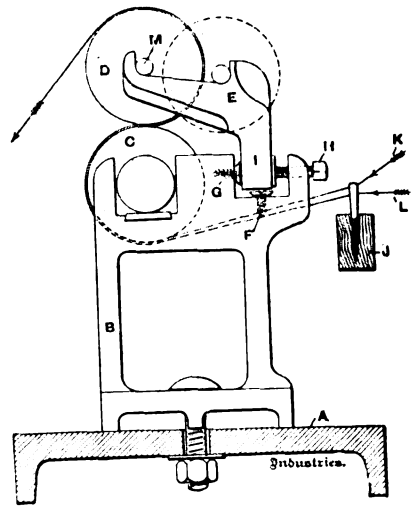


GRAIN GRINDING MILLS.—*H. H. Lake, London.* (*G. Zonca and G. dalla Bella, Venice.*)—A chilled steel cylinder with longitudinal grooves formed in its surface is mounted in bearings, and revolves in close proximity to a sector of the same material. The sector has graduated grooves in its concave surface, and means are provided for regulating the distance between the sector and the roller. The grain enters the narrow space between the sector and the roller, and as it descends it becomes more finely ground, owing to the space being continually reduced. Three claims are made.—No. 7141. May 16th, 1887. 6*d*.

MANUFACTURE OF STEEL.—*J. Riley, Glasgow.*—The walls of basic hearth steel making furnaces have hitherto been built of fire bricks consisting chiefly of silica, and the hearth of dolomite or other basic material. These continuous portions of these two surfaces tend to react upon one another when subjected to great heat, and the result is the formation of a fused slag. By this invention a vertical barrier of a neutral substance is interposed between the boundaries of the basic hearth and the walls of the furnace; this barrier is to have no part of the walls or any other weight resting upon it, so that it shall not be liable to displacement or crushing. The inventor claims the interposition of a neutral barrier in the form of an inner wall completely surrounding the hearth, the top of which wall is uncovered to the interior of the furnace.—No. 2896. February 27th, 1888. 6*d*.

MANUFACTURE OF IRON AND STEEL.—*P. C. Gilchrist, London.*—In converting phosphoric pig iron into iron or steel, the inventor charges a basic lined open hearth furnace with the pig together with as much lime or limestone as can be used consistently with a fluid slag, and from seven to eight times as much iron ore as there is phosphorus and silicon in the pig. The greater part of the impurities of the pig iron are eliminated by this treatment. One claim is made.—No. 7495. May 23rd, 1887. 6*d*.

PORTABLE RAILWAY.—*A. M. Leinwather & H. Glaser, Vienna.*—The cross section of the rails is made of a corrugated shape, and involves the principle of diagonal strutting. The two outer struts form guides, by which the wheels are kept on the rail, and the inner corrugations support the wheels. The rails are connected together by correspondingly shaped chairs, which embrace the lower parts and sides of the rails. Some of the chairs are provided with lateral eyes, so that the two rails may be connected by transverse gauge bars or chains. The carriages which run on these rails may have ordinary wheels, or they may be supported on balls which run on the rails. The inventors claim the ribbed rails, and the combination of the chairs and cross ties.—No. 9514. July 5th, 1887. 8*d*.



CALENDERING MACHINES.—*W. W. Urquhart, J. Lindsay, and R. Allan, Dundee.*—This invention is applicable to rolling machines which are employed for finishing woven fabrics and for rolling paper, and its object is to improve the method of communicating pressure to the rollers. The figure shows the arrangement fitted to a five roll calendering machine. The rolls A B C D E are mounted in the housings G; the bearing block H of the top roller is raised and lowered by means of a spindle J, which can be adjusted by means of a hand wheel K. The spindle is screwed through a block, which is pivoted between the inner ends of two plates forming a lever L; this lever is

centred on a pin in a bracket M, which is cast on the top of the gable G. The outer end of the lever is connected through the spring N to the upper end of a massive vertical bar O, which is made of such a weight as to be capable of lifting one end of the roller A. The lower end of the bar O rests upon the top of the ram P of a hydraulic cylinder. The top of the ram P is of a spherical form, and fits in a corresponding cavity in the bottom of the weight bar. The pressure of water in the cylinder Q is sufficient to raise the bar O and to apply the desired pressure to the top roller A through the lever L. Three claims are made for the manner of applying the pressure in calendering machines, for combining the counterweights with the pressure apparatus, and for interposing the springs, as described.—No. 2134. February 13th, 1888. 6*d*.

WELDING BOILER FLUES.—*G. H. Lloyd, Sutton Coldfield, A. L. Lloyd, Leamington, and H. Bewlay, Birmingham.*—A boiler flue constructed according to this invention is composed of two or more sections welded end to end. Each section consists of a cylinder whose ends are flanged; the body of each section may, however, be corrugated. The shaping of the edges of the sections may be effected either in the process of rolling the plates or in the process of rolling the sections when in hoop form. Before welding the sections together, the inventors bevel the edges of the plates, so that when they are brought together a V shaped groove is formed between the edges. In this groove is laid a strip of welding metal which projects above the level of the plates. The edges and the filling strip are brought to a suitable heat, and the joint is welded and finished with a swage which is adapted to leave a solid rib along the joint. By this means a weld is obtained which extends to the inner surface of the flue. Instead of a V groove being formed by the bevelled edges of the plates, the bevelling may be in a reverse direction, with the wider portion of the groove below. The rib of the welding strip is in this case made to project through and above the narrower portion of the interstice. During the welding operation the substance of the rib may be partially spread over the adjacent surfaces of the plates. Instead of producing V shaped grooves by bevelling the edges, a similar result may be effected by turning the edges of the plates upwards or outwards to a moderate extent. The welding operations are conducted by the aid of a gas or carburetted air flame; the tuyere is brought within a very short distance of the material under treatment. For welding joints in irregular work, the extremity of the tuyere or its fire brick facing is shaped so as to correspond with the contour of the plate, otherwise a large proportion of the gas would be wasted, and a risk of over heating would be incurred. The inventors claim: (1) The method of welding boiler flues, whereby the strength of the joint is greater than that of the normal thickness of the plate; (2) the employment of the strip of welding metal inserted between the bevelled edges; (3) the employment of a tuyere whose working face corresponds with the contour of the work under treatment.—No. 7828. May 28th, 1887. 8*d*.

DOUBLING AND TWISTING MACHINES.—*C. W. Lancaster, Accrington, Lancashire.*—This invention relates to that class of machines in which the continuance of the top roller in its working position is dependent on the continuity of the yarn. In order to insure the correct adjustment of the top roller in relation to the driving roller, the inventor makes use of supporting screws on which the cap bar is held in position. The arrangement will be seen on reference to the figure. The threads K L pass under the

driving roller C and over the top roller D; when the yarn is broken the top roller runs back in the groove in the cap bar E, and the delivery of yarn is checked. By means of the two screws F G and the set screw H, the cap bar can be adjusted with great nicety; the part I rests on the head of the screw F, and leans against G and H. The centre of the axis M can be adjusted so as to fall slightly to the right of a vertical line through the centre of the bottom roller. Recesses are formed in the circumference of the upper rollers near their ends for the purpose of keeping the yarn from slipping off the roller when the yarn is slack. Two claims are made for the method of adjustment by the adjusting screws F G H and for the recess in the upper rollers.—No. 17182. December 14th, 1887. 6*d*.

SHAPING THE TEETH OF BEVEL WHEELS.—*J. Lindsay & R. Allan, Dundee.*—The object of this invention is to improve the shaping of the teeth of bevel wheels which are made with inclinations to the planes passing through the axis of the wheel. The teeth are formed so that each half is made of a true conoido-helical form. The patterns for making moulds correspond either to a complete wheel or to only one or two teeth. In both cases the pattern for one half a tooth is cut out separately from the pattern for the other half, so that the cutters may work beyond the ends of the half teeth. For cutting the patterns the inventors employ a special modification of the machinery described in the specification of Patent No. 4122 of 1878. In this modification an additional reciprocating rotary motion is given to the part carrying the pattern, and this motion, together with the other motions, gives the conoido-helical form to the teeth. This invention may also be applied when the conoido-helical teeth are not made with one half of each at an angle with the other, but with the whole of each tooth inclined the same way. Two claims are made, one for the form of the teeth, and one for the special adaptation of the machinery as described.—No. 11515. August 24th, 1887. 8*d*.

PAPER MAKING MACHINES.—*J. Wood, Leith, Midlothian.*—This invention has been designed for the purpose of giving the paper pulp a motion which will cause the fibres to settle together in a regular manner while the water is drained from them. Two endless wire cloths are used; the first receives the fresh pulp and delivers the web at the other end to the second, by which it is carried through the usual couch rolls. The first wire cloth passes horizontally over a number of rollers. The frame of the rollers is supported in such a way as will admit of a horizontal motion being imparted to it. In one modification the frame is carried by four or more legs made with hemispherical ends, the upper ends fitting in corresponding cavities in the under side of the frame, and the upper ends resting in cavities in stools on the bed. The motion is imparted to the frame by cranks or eccentrics on two vertical shafts. The rollers at the end of the frame are larger than the intermediate rollers, and the roller at the delivery end is surmounted by a roller covered with felt for the purpose of giving some pressure to the web. The entering end and roller of the second wire cloth is placed at a suitable distance from the delivery end of first wire cloth, so that the motion which the web receives from the first wire cloth may not interfere with its progress on the second. The two bands are ordinarily driven at the same speed, but gearing may be introduced for enabling the attendant to adjust their relative movements as desired. One claim is made.—No. 8160. June 7th, 1887. 8*d*.

ELECTRICITY.

ELECTRIC ARC LAMPS.—*W. Mackie, London.*—This form of lamp has all the usual distinguishing features of a differential arc lamp, but the feed is governed by the action of the shunt coil. The main coil is free to move, and is placed in such a position that it is capable of striking an arc, and afterwards of affixing itself to the core of the shunt solenoid. The main solenoid coil is itself suspended upon one end of a balance beam, the opposite end of which is weighted. This coil is suspended over its own core to a sufficient distance to enable it in its descent to strike the necessary length of arc. The solenoid core is connected through a dash pot to the core of the shunt solenoid, and the total weight of the cores and the interposed dash pot is greater than that which is necessary to strike the arc; they will thus remain stationary until the shunt coil becomes of sufficient strength to lift them. By another method of accomplishing the object of this invention, the main solenoid coil is fixed and has two iron cores; one of them actuates the striking gear, and the other is attached by a non-magnetic distance piece to the shunt solenoid core. These main cores have a space between them at starting, and the amount of iron protruding out of each end is equal. The action of the current in the main coil will tend to draw both cores into it, and the core striking the arc will then attach itself on to the other core. As there would then be an equal amount of iron through each end of the coil, very little power would be required to move these combined cores up and down through some distance. The shunt coil controls this system of cores and regulates the feed, without the main coil having any appreciable influence on it. A brake is sometimes used for the purpose of striking the arc and controlling the feed. Four claims are made for the application of the movable main coil, as a connecting link between the feeding gear and the regulating gear of the lamp, for the regulation by means of the shunt coil, which may be partially retarded from feeding by the action of the main coil, and for the brake.—No. 7184. May 17th, 1887. 8*d.*

ELECTRICAL TRANSFORMERS.—*W. M. Mordey & C. E. Webber, London.*—Fig. 1 is a side view, Fig. 2 an end view, and Fig. 3 a transverse section of one form of a transformer constructed according to this invention. P is a primary conductor, and K a secondary wire; the sections of these two wires are in the inverse ratio of the tension of the inducing and induced currents. These coils are respectively connected to the terminals O and L. The pieces of thin sheet iron A have each an opening N through them, and the pieces of iron B have no opening through them. The pieces A or B have an insulating substance on one side, such as varnish or paper. For the sake of economy the pieces A and B are so proportioned that the pieces cut out of A may serve as the pieces B. The pieces A are placed around or over the conductors P K, and the pieces B are inserted between the pieces A, so that A and B shall alternate

FIG. 1.

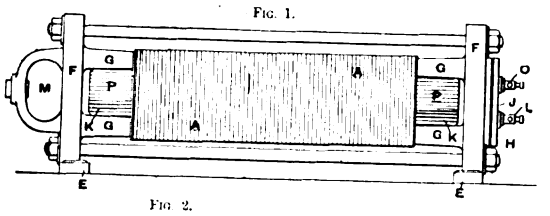

FIG. 2.

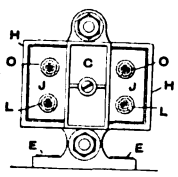

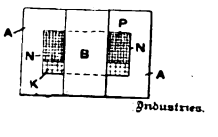

FIG. 3

Industries.

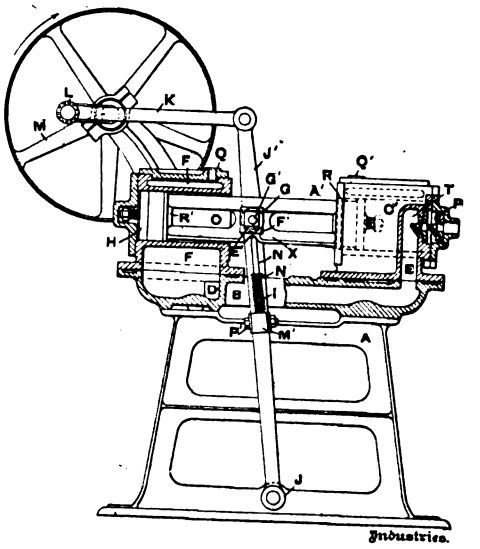
with each other. The pieces B pass through the coils, as shown in Fig. 3, and are in contact with the pieces A. As there is an insulating material on one side only of the pieces A or B, electrical contact only exists between the adjacent pieces on one side of each piece. The pieces are held together by the bolts passing through the end plates C F. The plate C carries a frame H, in which an insulating board J is supported, and on the plate F is formed a loop M, by which the apparatus is suspended. The extensions G are for the purpose of pressing the iron strips together when the bolts are screwed up. The spaces between A and B may be occupied by U shaped pieces of iron; but it is preferable to leave them open, in order to provide for ventilation. The end portions of the coils may be occupied by slips of sheet iron, varnished on one side; they are placed in the end portions of the coils at right angles to the pieces B, and the outer portions of the ends of the coils are covered by U shaped pieces of sheet iron. These pieces are placed at right angles to the pieces A, and meet the slips of iron occupying the inner portions of the ends of the coils. These parts are, however, preferably dispensed with, and are not shown in the figures. Four claims are made for this form and for another modification.—No. 6917. May 11th, 1887. 8*d.*

ELECTRICAL MEASUREMENTS.—*P. B. Elwell, Wolverhampton.*—The instrument here described is a combination of a volt meter, ampère meter, and electric meter. A high resistance solenoid is employed for indicating the e.m.f., and a low resistance solenoid for measuring the current. The high resistance solenoid is in a shunt between the lead and return mains. Coincident or parallel with the axis is mounted a spindle of non-magnetic material, which carries a wheel or other carrier within the solenoid; an iron bar or bundle of wires is fixed to the spindle in a direction parallel to the solenoid. Within the solenoid and close to the coils is fixed an iron bar or curved plate, which occupies such a position that the swinging bars may be adjacent to it when at rest; the weight of the bars always brings them to rest at the bottom. A platinum contact or a pair of contacts is attached to the fixed bar or plate, and to the rotating bar fixed upon the carrier; the circuit through the solenoid may thus be closed when the fixed bar and the moving bar on the spindle are at the point of nearest approach. The speed of the rotating spindle depends on the e.m.f. of the current, and this speed may be employed to indicate the e.m.f. The low resistance solenoid is wound with a few turns of thick wire, and is inserted in the main circuit. Within the solenoid are two or more bars of iron or bundles of iron wire, which are carried by non-magnetic carriers, mounted on central concentric axes. Upon one side of the interior of the solenoid is fixed a piece of iron similar to that in the high resistance solenoid. A pointer may be attached to one of the suspended bars. On passing the current through the coils the bars become similarly magnetised, and they move through a space depending on the strength of the current. By suitable gearing the angular motion of the suspended arms may be caused to traverse a small friction pulley upon the face of the disc on the high resistance solenoid. The friction pulley may have a flexible centre, obtained by connecting the rim to the boss by means of india-rubber or springs. Upon the axis of the friction pulley is mounted a worm pulley, which operates a suitable counting mechanism. The number of revolutions of the counting apparatus in a given time will be governed by the speed of the disc, which is controlled by the quantity of the current; the meter will thus give a record of the value of the current. The inventor makes four claims for the combination and arrangement of the high resistance solenoid, having one fixed magnetic bar, one or more rotating magnetic bars, and a rotating disc; with the low resistance solenoid, having one fixed magnetic bar and one or more rotating bars, a rack and pinion or equivalent device for transforming rotary into reciprocating motion, and a friction pulley operated by the rotary disc, for the purpose described.—No. 4447. March 25th, 1887. 8*d.*

ELECTROMETERS.—*A. Le N. Foster & F. W. Andersen, London.*—This invention relates to the class of electrometers in which a movable disc is mounted on an axis perpendicular to the plane of the needle. In the improved apparatus the movable needle is made bipolar, so that it receives two opposite electrical charges simultaneously. The needle is arranged between two pairs of inductive plates, which are charged with potentials of opposite polarity at the same time as the needle. The needle is constructed of a circular disc of mica, and is provided with two insulated coverings of tin foil. The needle is suspended from its centre, and electrical connections are made respectively from the two metallic coatings to two fixed points from which the coatings are charged. The electrical connections are made through the two ends of the suspendid axis. When several needles are employed, they are fixed upon one axis; the metallic coatings of the discs are electrically connected together in two sets in such a manner that one coating on every needle is positively charged, while all the other coatings are negatively charged. Two sets of inductive plates are arranged so as to enclose and partly cover the needles. These plates are fixed opposite one another symmetrically with the axis of the needle, and are constructed either of solid metal plates or of insulating material covered with a conductor. In one modification, instead of constructing the needles out of discs, the needles are made in cylindrical form with the metallic coatings symmetrically disposed around the circumference, and the inductive plates are constructed in a semi-circular form to envelop the needle. The inventors claim: (1) The bipolar needle arranged to oscillate between bipolar inductive plates and charged with potentials whose difference it is desired to measure; (2) arranging the series of needles upon the common axis; and (3) the construction of the instrument, as described.—No. 6104. April 26th, 1887. 8*d.*

DYNAMOS.—*C. Coerper, Ehrenfeld, Cologne, Germany.*—The object of this invention is to reduce the speed of revolution of the armature or field magnets without detracting from the value of the machine. This is accomplished by rotating the magnetic field in an opposite direction to the armature, and a special device for effecting these contrary revolutions is designed by the inventor for the purpose of reducing the wear and tear to the greatest extent possible. The motors are made with one or more cylinders. In motors with one cylinder, two connecting rods are actuated by one piston rod; one of the connecting rods turns a crank shaft on which is mounted the field magnets, and the other turns a second crank shaft on which the armature is secured. In motors having two cylinders, the crank shaft is divided, so that one cylinder with its crank shaft drives the magnetic field, while upon the crank shaft of the other cylinder the armature is fixed. In this manner the number of revolutions of the generators is reduced one half. The inventor claims the construction of generators in which the magnetic field and armature are rotated in opposite directions by means of two connecting rods in combination either with the piston rod of a cylinder, or with two or more piston rods of two or more cylinders.—No. 2308. February 15th, 1888. 6*d.*

CHEMISTRY.



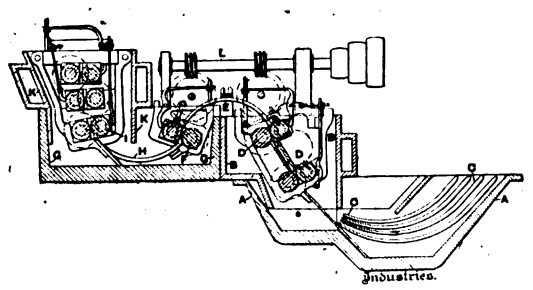
LACQUERS AND VARNISHES.—*F. Crane, Short Hills, New Jersey, U.S.A.*—The object of this invention is to prepare a varnish or lacquer which does not dry so rapidly as those at present employed in coating metals. For the methyl alcohol or methylated spirits the inventor substitutes amyl alcohol, or fusel oil, or amyl acetate. A medium varnish prepared on this principle may be composed of methyl alcohol five gallons, fusel oil four gallons, benzine four gallons, gum resin ten gallons. Six claims are made.—No. 7376. May 20th, 1887. 6*d.*

WASHING ORES.—*M. Kennedy, Ulverston, and G. Green, Aberystwith.*—The ore is first passed through an inclined iron cylinder together with a stream of water. An internal screw, made of angle iron, elevates the ore, and at the same time the loosened clay escapes with the water to the bottom of the cylinder. The rough ore having been cleansed passes out at the upper end of the cylinder, and falls upon a picking and shaking table. A length of 3ft. at the upper end of the cylinder is perforated, so as to allow the finer particles of the ore to pass through into a trough, and on to a sieve which is of finer mesh than the perforation of the cylinder. The material which does pass through the sieve is delivered to a "jigger," which separates the quartz and silicious matters from the ore. A series of sieves and jiggers are employed, and the meshes of the sieves become gradually finer. All the fine particles which pass through the mesh of the third sieve are conveyed by a launder to a first water current classifier, which deposits the roughest portions on a propeller "buddle;" the particles are scrubbed on the buddle by wire brushes and oblique scrapers; the water and materials passing over the first classifiers are led to a second, which delivers the material to the second propeller buddle. One claim is made for these combinations.—No. 7998. June 3rd, 1887. 8*d.*

A NEW MONO-SULPHO ACID OF ALPHA-NAPHTHOL.—*A. Liebmann and A. Studer, Manchester.*—In preparing the new mono-sulpho acid of alpha-naphthol, the inventors mix one part of alpha-naphthol with four parts of concentrated sulphuric acid. This mixture is maintained at a temperature of 130°C. for about an hour, and resulting sulpho acids are then converted into their corresponding barium salts. These salts are afterwards suspended in about ten parts by weight of water, and exposed to the action of a stream of gaseous hydrochloric acid. When the water and its contents are saturated with the gas, they are heated for about two hours in a reversed condenser; the excess of hydrochloric acid is evaporated, and the precipitate of barium sulphate is filtered off. The solution of the new sulpho acid is neutralised by the addition of barium carbonate, and on evaporation the dry barium salt is obtained. The barium salt is easily soluble in water and in ethyl alcohol which has been slightly diluted with water. The new sulpho acid has properties by which it can be readily distinguished from others of the same class. It does not on nitration lose its sulpho group, but yields dinitro-sulpho-alpha-naphthol, which none of the hitherto known mono-sulpho acids of alpha-naphthol do. It also combines with diazo compounds to form dye stuffs. One claim is made for the production of this new compound.—No. 7812. May 28th, 1887. 6*d.*

MISCELLANEOUS.

AIR PUMPS.—*E. M. Eckardt, Dresden.*—In the accompanying figure, A is the frame on which the pump is mounted, and B is the casting which connects the air chambers and the water mantle of the cylinders C C¹. The valve boxes of the cylinders contain the pressure valves T, through which the compressed



Industries.

air enters into the air collector in the casting B. The suction valve P is arranged in the lid of the cylinder; D and F are the ways for the cooling water, and Q Q¹ are the outlet openings for it. The pistons are connected by the beams A¹ and X, and receive their motion from the lever J, whose upper end is connected by a rod K to the crank L on the strap drum M. The upper end of the lever J¹ is bifurcated, and embraces a slide G, whose trunnions G¹ bear in the forked arms. The slide moves in the slot E¹ in the massive part F¹ of the piston. The piston is supported by means of a device for decreasing the wear and tear. This device consists of a block M¹, which slides in the forked part of the lever J¹, and which can be fixed by means of a bolt P¹. The piston is supported by a rod N which fits into a recess in X, and the rod N is provided with a collar N¹ against which the spring I presses. The interior of the pistons R¹ are connected with each other by a tube through the rod A¹, and a valve in the interior of the pistons allows the air to pass from the interior to the space behind the pistons. If the driving wheel M is rotated in the direction indicated by the arrow, the piston will move from C to C¹, and the piston R¹ sucks, and the piston R presses. In consequence of the air pressure behind R, the valve in R¹ will be closed, and compressed air will flow into the hollow space of the piston, and through the tube A¹ into the piston R¹. In carrying out the reverse movement, the piston R¹ will press, and the piston R will suck. Three claims are made for the application of the hollow rod for the adjustable rod N for the purpose described.—No. 17. January 2nd, 1888. 8*d.*

HYDROMETERS AND SACCHAROMETERS.—*J. J. Hicks, London.*—Certain additions to the usual parts of these instruments have been designed by the inventor, for the purpose of preventing them revolving in the liquid, and of forming supports which will enable them to stand upright when out of the liquid. To the lower end of the stem of the metal hydrometer are soldered a number of flat wings, which are so formed as to serve the above mentioned purpose. In some cases the wings extend sufficiently far from the stem to serve as a guard for the floating bulb, so that when the instrument is laid down on the table the bulb shall not be in contact with it. In applying this invention to glass hydrometers, the inventor fuses three or four plates of glass upon the weighting bulb or upon the lower part of the stem. Two claims are made, for fixing the wings to the metal hydrometers and saccharometers, and for fusing the plates to the glass instruments, as described.—No. 14169. October 18th, 1887. 8*d.*

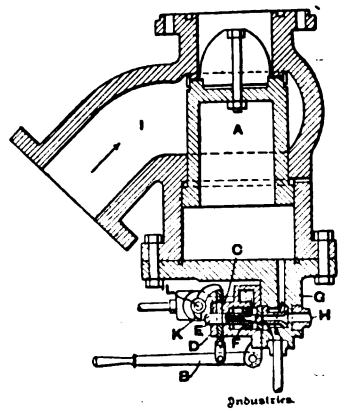
COATING METAL PLATES WITH TIN.—*D. Edwards, R. Lewis, and P. Jones, Swansea.*—The tinning vessel is constructed as described in Patent No. 5702 of 1885, except that apparatus is introduced for the purpose of passing the plates along without handling them. The accompanying figure illustrates this improvement. A is the tinning vessel containing the molten metal, and B is the grease bath above it; C is the rack of curved guide bars between which the plates are inserted. The rack is formed to receive three plates, two of which remain at rest in the bath, whilst the third is being pushed forward to the withdrawing

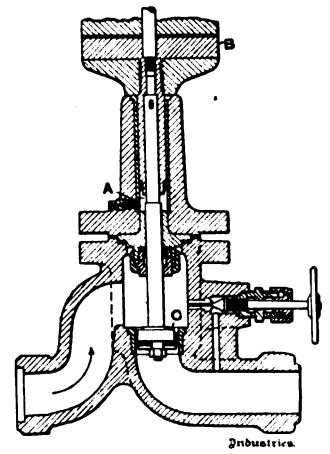
rolls D. As the plates emerge from between the upper pair of rolls, they pass below the curved guide bars E, which deflect the course of the plates and conduct them to a pair of rolls F. These rolls are necessarily immersed in the molten metal contained in the finishing pot G, otherwise the scruff floating on the surface would adhere to them. As the plates pass from the rolls F they come against curved guide bars H, which turn their course upwards and lead them to the lowest pair of rolls I. The plates are then carried upwards through the grease contained in the pot K. The wheels which drive the rolls D and F receive their motion from worm gearing on the driving shaft L. The inventors make three claims for the apparatus for coating metal plates, so constructed that the plates, as they are raised by rolls through a grease or flux bath from a vessel containing a coating metal, are deflected downwards by curved guides, and without being passed between any nipping rollers, are conducted to rolls completely immersed in a second bath of molten coating metal. —No. 7139. May 16th, 1887. 8*d.*



ENDLESS BANDS FOR THE CONVEYANCE OF MINERALS.—*J. Clarke, Alfreton, Derbyshire.*—Certain improvements are here introduced into the construction of the metal bands used in conveying minerals. In order to prevent the escape of the mineral while the drum is being passed, the inventor makes one edge of each plate to underlap the adjoining plate; the underlapping edge is curved to the arc of a circle, the centre of which is coincident with the centre of the pivot of the links. The overlapping or plain edge of the plate moves in close contact with the curved underlapping edge, and no space is left for the escape of the mineral. To allow of this curvature of the underlapping edge, the curved edge may be notched at one or more points according as there are two or more sets of links in the chain; there is thus room in the notches for the adjoining link to clear the plate when the belt is straight. These notches, however, allow the dust to escape through them, so that instead of notching the curved edge, the inventor sometimes forms a notch in the adjoining link, into which the curved edge will fit when the belt is straight. The strength of the plates is further increased by the plate being embossed with transverse corrugations running parallel with the curved edge. The belt may, however, be strengthened by the part of the plate between the links being buckled by Mallett's method. Two claims are made, for the manner of preventing the escape of the minerals, and for the means of strengthening the plates.—No. 14617. October 27th, 1887. 8*d.*

BOBBINS AND SPOOLS.—*G. O. Boynton & F. C. Johnson, Boston, U.S.A.*—This invention consists of an improved method of protecting the bearing ends of bobbins and spools. A portion of the wood is turned away, and a copper wire is wound round the reduced end. The end, after being coated with some metallic varnish, is immersed in an electrolytic bath. When there is a sufficient accumulation of metal, the bobbin is removed, and the deposited metal is turned in a lathe. A protective bearing is thus formed on the end of the bobbin. Four claims are made for this bobbin protected at its ends.—No. 3468. March 6th, 1888. 8*d.*

BLADES OF AIR PROPELLERS.—*F. J. Crossley, London.*—The object of this invention is to form a surface which shall replace the screw surface at present employed. In a circle having a diameter about one quarter that of the propeller, and having for its centre the point which represents the vertical trace of the axis, as many points are taken as the propeller is to have blades. As the centre of the circle represents the end view of the axis, so each of these points will represent the vertical trace of other lines running in the same direction as the axis. The generating line of the surface turns upon each of these points in succession, but the end which is in this point does not advance along the line of which that point is the vertical trace. One end of the generating line is made to coincide with one of the points in the circle, and the line is in contact with the line of which the adjacent point is the end view; it is prolonged beyond its point of contact with that line until its outer end meets a plane, which cuts the axis at a given distance from the plane of the circle; by the intersection of this plane with the generating line the diameter of the propeller is determined. The generating line is not at right angles to the axis in its first position, but the end on the circle is in advance of the intersecting plane. When the line is moved it is turned round the point in the circle, and that point does not advance. The outer end of the line advances towards the plane in which that point is situated when it is at right angles to the axis; passing through this plane it completes the generation of the surface by finishing at a greater or less angle with the plane than at first, but inclined in the opposite direction. In making this movement, the outer end of the generating line should follow a curve which becomes more and more parallel to the axis the further it advances from the plane which it originally touched. The whole or part of the surface generated forms one blade or wing of the propeller or fan, and the surfaces of the other blades are formed in the same manner, starting from the other points in the circle. The generating line may be straight or curved, or partly curved and partly straight. Six claims are made.—No. 7672. May 26th, 1887. 8*d.*



GERMAN PATENT ABSTRACTS.

ORDNANCE.—*N. W. Pratt, New York.*—This invention relates to an improvement in automatic valves for regulating the supply of compressed gases used for propelling projectiles. As long as the compressed gas acts on both sides of the valve A, the latter is kept shut. After inserting the projectile the lever B is pressed downwards, thereby bringing the perforation C of the

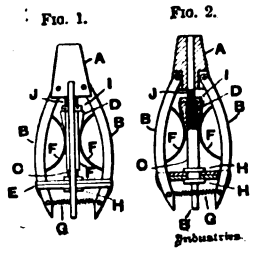
bolt D opposite to the piston rod E, and releasing E. As the pressure of the compressed gas is greater on the larger piston F than on the smaller one G, the latter one is moved to the left, thereby opening the exhaust H and relieving the pressure under A, which opens by its own weight, allowing the compressed air to enter through I, behind the projectile, which is discharged. When G is opened the piston rod E actuates the lever K connected to a piston valve L, which is thereby turned into such a position as to relieve the pressure on F. The compressed gas then forces G to the right, thereby closing the exhaust H, and an equilibrium is again established above and below A, so that the latter is closed after the discharge of the projectile. The lever B is then moved upwards and locks the piston rod E, while the upper end of D actuates a lever connected to L, and reverses L, thereby bringing the apparatus back to the same condition as before discharging the shot.—No. 42751. June 28th, 1887.

SAFETY VALVE.—*H. Brewer & Co., Höchst a. M.*—This safety valve is intended for automatically closing a high pressure main in case of breakage of a pipe. As long as the pressure is normal

the piston valve C is kept open on account of the difference of area. If a pipe breaks, the valve C is closed by the pressure of the water and the weight B. A dash pot A is provided for checking the too rapid descent of C.—No. 42622. July 1st, 1887.

UNITED STATES PATENT ABSTRACTS.

WHIP ROLL FOR LOOMS.—*A. F. Parker, Charleston, South Carolina.*—The whip bar, to which the bearing bar is attached, is provided at its ends with V shaped projections fitting into corresponding recesses in the levers. The levers are capable of vertical adjustment by means of the boxes in the loom frame, and the springs employed for holding the bearing boxes against the warp have nut and bolt connections with the levers; a variation of the tension is thus obtained. Two claims are made.—No. 371720, dated 24th April, 1888.



SEA OILING CARTRIDGE.—*A. H. Walker, Hartford, Connecticut.*—The cartridge consists of an elongated cylindrical shell, at the rearward end of which is a separate chamber containing powder. At the end of the oil chamber nearest to the powder is placed a weight, which tends to make the cartridge sink in the sea. At the opposite extremity is an air chamber, which sustains the cylinder in an upright position in conjunction with the weight. The wall of the cartridge is perforated so finely that the oil will not escape into the air, but directly the cartridge is immersed in the water the oil passes through the holes in the manner required. Three claims are made.—No. 380369, dated 3rd April, 1888.

SOAP.—*R. A. MacCullough, Milwaukee, Wisconsin.*—A certain amount of borax is added to the water contained in an open kettle, and afterwards some liquid caustic soda, cocoa nut oil, and tallow are mixed with the other ingredients. The mass is heated to a temperature of 190°F. to 240°F., and is agitated until it becomes homogeneous. A second mixture is made by melting a similar quantity of cocoa nut oil and tallow, and running them into an open tank; about the same proportion of liquid caustic soda is here added. On the completion of this process the two liquid masses are mixed together with a specified quantity of silicate of soda and dissolved starch. The saponification becomes complete after the whole mass has remained for an hour or so in the tank, during which time it is occasionally agitated. One claim is made.—No. 381503, dated 17th April, 1888.

LET-OFF MECHANISM FOR LOOMS.—*G. F. Hutchins, Worcester, Massachusetts.*—The rolls between which the pile warps pass are geared together, and are actuated by a ratchet and pawl. This mechanism is operated from a harness lever through a suitable combination of links and knee levers, according to the requirements of the pattern. A hand lever is provided, which serves to disconnect the train for actuating the warp rolls, and also to unclutch the operative shaft from the driving gear when desired. One claim is made.—No. 381787, dated 24th April, 1888.

FLUE CLEANER.—*C. G. Davidson, Union City, Pennsylvania.*—The flue cleaner here illustrated is adapted for cleaning the flues of any sized boiler. A stem C is fixed to the head A, and is provided with a screw thread J and with a square recessed head H at its outer end. Four arms B are pivoted to the head A, and carry the semi-circular scrapers E, and notches in the

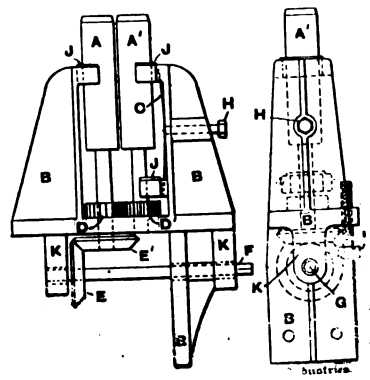


FIG. 1. FIG. 2.

scrapers embrace the steam head H. The springs F keep the arms B expanded, and the spiral spring G holds them together. In order to adjust the width of the scrapers to the diameter of the tube, the nut I is screwed up or down the thread. The wedge D is thus altered in position, and the springs F and the arms B are either forced out or retracted. Three claims are made for this flue cleaner.—No. 379564, dated 20th March, 1888.

SEPARATOR.—*J. J. Lowden, Boston, Massachusetts.*—This apparatus is employed for separating dirt and grease from water as it flows through pipes. A chamber is inserted in the length of the pipe, and inside the chamber three screens are fixed at right angles to the flow of the water. A series of perforations in the three plates are located at such points that the water shall pursue a sinuous course while passing through the chamber. This baffling of the current arrests the passage of impurities in the water. At the bottom of the chamber is a wide opening which leads to a waste pipe. Inside this bottom extension is an automatic float valve, which allows a free course to the sediment into the waste pipe when sufficient has accumulated to operate the valve. Three claims are made for this separator.—No. 381150, dated 17th April, 1888.

SIDE DRESSER FOR BAND SAWS.—*C. E. Cleveland & J. Hanson, Fort Waine, Indiana.*—The accompanying illustration shows the arrangement of the side dress for band saws designed by the inventors. The rollers A A¹ are mounted on shafts, to which the gear wheels are also fixed. Their ends are bevelled as

shown, and their bearing boxes J are made adjustable by means of the spring C and the nut H. The rollers acquire their rotary motion from the driving shaft F by means of the mitre gear E E¹. The whole is mounted in the frame B. Three claims are made for this side dresser.—No. 380089, dated 27th March, 1888.

The full specifications of the British and United States patents, and the Official Journals of the German Patent Office, from which the above abstracts have been compiled, and the Official Journal of the United States Patent Office, may be seen by subscribers and clients at the Reading Room, Manchester Office of INDUSTRIES, *where also Patent Indexes from* A.D. 1617 *may be consulted. Copies of the British specifications may be obtained on application to* H. READER LACK, Esq., *Comptroller-General, Patent Office, Southampton Buildings, London, W.C. The published price must be remitted, together with a sum sufficient to cover postage, which may be reckoned at* ½*d. for every* 10*d. or fraction of* 10*d. Remittances exceeding one shilling must be made by Post Office Order.*

IMPROVED CYLINDER LUBRICATOR.

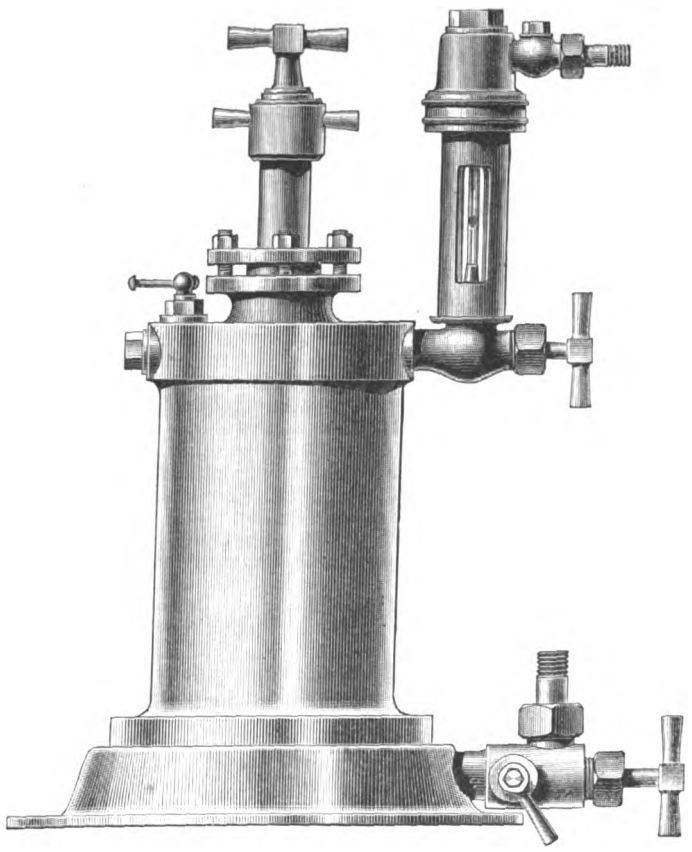

Fig. 1.

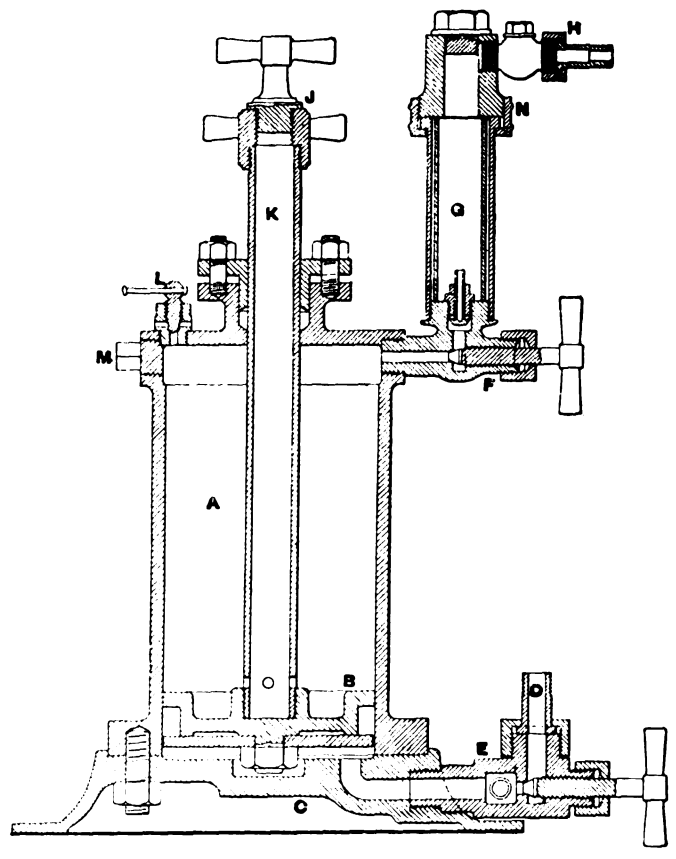

Fig. 2.

IMPROVED CYLINDER LUBRICATOR.

The above illustrations represent an improved steam cylinder lubricator put on the market by the Steam Cylinder Lubricator Company, Standard Chambers, King-street, Manchester. This lubricator is of the sight feed type, *i.e.*, the lubricant may be seen passing through a glass tube, thereby enabling the attendant to regulate the supply of oil to the required amount. The lubricator works in the following manner: The piston B, which is provided with asbestos packing, is brought into the position shown in Fig. 2, the screw plug J is removed, and the oil poured into the hollow piston rod K, entering into A through the perforations in K, just above the piston B. The air in A escapes through the valve L as the oil gradually fills A. J is then replaced, and the valve D opened, admitting steam under the piston B, which is forced upwards, owing to the difference in area between the top and bottom of B. The oil passes through the valve F into the sight feed G, and then through the pipe H to the steam pipe or steam chest of the engine. The supply of oil is regulated by the valve F. E is a run-off valve, and M a screw plug, which may be removed and another sight feed inserted. C is the base on which the lubricator is fixed. The advantages of this lubricator are as follow: It is easily fixed, and by attaching two or three sight feeds the lubricator may be used for supplying two or three cylinders at once. The oil is displaced, not by the accumulation of condensed steam, but by the pressure of steam from the boiler on a piston, the action of the lubricator thus being positive. The piston rod serves as a gauge, indicating the amount of oil left and the need of replenishment. The apparatus may be regulated to deliver large or small quantities of the lubricant, the amount varying from one drop to two hundred drops a minute. As no condensed steam comes in contact with the oil, the glass tube in the sight feed is kept clean, and breakage of it arising from the heat due to condensed steam is also prevented. As will be seen, the apparatus is compact and very neatly designed.

THE IRON AND STEEL INSTITUTE.

As we briefly mentioned in our last week's issue, the annual meeting of the Iron and Steel Institute was held on Wednesday and Thursday, the 9th and 10th inst., at the Institution of Civil Engineers, the President, Mr. Daniel Adamson, occupying the chair. Sir Frederick Abel was elected a member of the Council in place of the late Mr. Henry Robertson, and, on the proposal of the President, H.R.H. the Prince of Wales was elected an honorary member of the Institute. The Bessemer gold medal for 1888 was presented to the President, in the name of the Council, by Sir Henry Bessemer, who reminded the members that some thirty years ago, before the Iron and Steel Institute had been established, there was great difficulty in inducing manufacturers in the iron and steel trades to adopt improvements. Even in Sheffield, the stronghold of steel making, the speaker could not find one single manufacturer who would sympathise with him, and who would assist him in the introduction of his new process; but, fortunately for him and the world, there was outside of Sheffield a man who could appreciate the process, and who was determined to investigate it. That was his friend, Mr. Daniel Adamson, who, after convincing himself by trials of the best way to work up the new material, adopted it for boilers with the most beneficial results. Six boilers, 7ft. in diameter and 30ft. long, made from this material by Mr. Adamson twenty-two years ago, are still at work on their old seatings. It was perfectly well known to members of the Institute that the services rendered by Mr. Daniel Adamson to the steel industry generally were of the highest character, and they would all agree that he had fairly and honourably earned the medal which the speaker then had the pleasure of presenting to him.

Mr. Daniel Adamson, in accepting the medal, thanked Sir Henry Bessemer and the members of the Institute for the honour they had conferred upon him, and he explained that he was induced to try Bessemer metal because, in 1877, some puddled steel had passed through his hands which turned out unsatisfactory. He visited Sir Henry Bessemer's experimental works at Sheffield, and also saw the new material rolled at Messrs. Brown's, of Rotherham, where he was allowed to cross-examine the workmen, and the favourable opinion entertained by them induced him to make experiments in his own works. At first there was some trouble, due to the material lacking uniformity; but by annealing every plate and testing every plate himself, he was able to produce a perfectly reliable material. He had now 3000 of his boilers working, the majority being made of Bessemer steel. So thoroughly was he satisfied with the advantages of the new material, that he eventually solicited a license from Sir Henry Bessemer to manufacture it, and the result was the works at Penistone, now owned and carried on by Messrs. Charles Cammell & Co., Limited. These were the first works specially constructed to produce Bessemer metal to the exclusion of every other kind of steel. In his endeavour to introduce the new material he had been largely assisted by the late Mr. John Platt, of Oldham, and by Mr. William Richardson of the same firm, also by Mr. John Tosh, the managing director of the North Lancashire Iron Works, who was the first to give him orders for locomotives made entirely of steel. The President then delivered an address of which the following is an abstract:—

This being the fortieth meeting since the formation of the Iron and Steel Institute in 1869, it is satisfactory to note that the Institute continues in a flourishing state. During the year of formation there were elected 336 members, whilst in the following eighteen years a total of 1758 members was elected, or a yearly average of over ninety-seven. The total number of members elected from the beginning up to date is 2116. Allowing for deaths and resignations, the actual number of members would at present be about 2000. The importance of the Institute will be seen from the fact that the production of pig iron in the United Kingdom, in the United States of America, and in the leading iron producing countries of Europe, amounted last year to 21,832,663 tons. The total quantity of manufactured iron and steel for the years 1884 to 1887 inclusively is given in the annexed tables, which show that whilst the production of manufactured iron decreases that of manufactured steel increases:—

Table I.

Total Production of Manufactured Iron in Great Britain in the Years 1884, 1885, 1886, and 1887.

Year.	Tons produced.	Decrease since 1884. Per cent.
1884	2,237,535	—
1885	1,911,125	14·588
1886	1,616,701	27·747
1887	1,701,312	23·965

Table II.

Total Production of Bessemer Steel Ingots in Great Britain in the Years 1884, 1885, 1886, and 1887.

Year.	Tons produced.	Increase since 1884. Per cent.
1884	1,299,000	—
1885	1,304,000	0·462
1886	1,570,000	21·048
1887	2,064,000	59·136

Table III.

Total Production of Open Hearth Steel Ingots in Great Britain in the Years 1884, 1885, 1886, and 1887.

Year.	Tons produced.	Increase since 1884. Per cent.
1884	475,250	—
1885	583,918	22·865
1886	694,150	46·059
1887	981,104	106·439

Digitized by Google

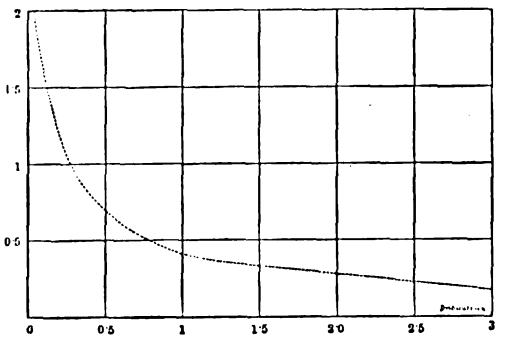
The production of Bessemer steel in the eight chief iron and steel producing countries of the world amounted last year to 7,269,767 tons, and that of open hearth steel to 1,672,340 tons, both figures showing a considerable increase over the previous year.

The use of Bessemer metal results in a great saving to railway companies and to shipowners. From Table IV., supplied by Mr. Parker of Lloyd's, it will be seen how rapidly mild steel has taken the place of iron for shipbuilding purposes.

TABLE IV.

Table showing the Annual Increase since 1878 in the Use of Steel for Steamers and Sailing Vessels built under Lloyd's Survey.

	Approximate weight of material.			
	Steel.		Iron.	
Year.	Steam. Tons.	Sail. Tons.	Steam. Tons.	Sail. Tons.
1878	2,682	—	243,717	66,897
1879	—	—	78,411	25,603
1880	21,895	1,002	268,433	24,009
1881	41,019	1,900	354,301	41,190
1882	69,269	7,486	403,644	67,711
1883	84,931	8,515	445,375	68,818
1884	65,386	8,016	274,189	78,011
1885	92,549	18,341	89,104	96,020
1886	96,583	18,352	49,320	58,627
1887	195,907	14,433	24,052	28,150



Steel ship plates can now be obtained at about 30s. per ton more than iron plates; but the reduction of the scantlings, due to the greater strength of steel, practically counterbalances the increased cost, so that by adopting steel shipowners obtain a vessel of superior material, and capable of carrying about 4 per cent. more cargo. The introduction of steel boilers has conferred a further boon on the shipowner, because allowing of a higher pressure, and consequently of more economical engines. For the last four years Lloyd's have scarcely had an iron boiler submitted to them for approval, whereas during each of those years there have been built under the inspection of the surveyors about six hundred steel boilers, representing about 24,000 tons of material. The improvements brought about by the introduction of steel has resulted in a saving of 25 per cent. in fuel, whilst at the same time increasing the carrying capacity of the vessels by about 4 per cent. The introduction of steel for bridge building has greatly widened the capabilities of the civil engineer, and it is not too much to say that a gigantic structure like the Forth Bridge could not be built with iron. In certain details of machinery, however, steel has not yet been able to supersede iron, especially when case hardened parts are required. In connection with this subject the President quoted from a letter received from Mr. T. Hurry Riches, of Cardiff, who did not find steel economical either for slide bars, motion work, or for outside crank pins, for which purposes case hardened iron surfaces were much better. Messrs. Platt Brothers and Co., of Oldham, state that notwithstanding careful trials, steel for case hardening purposes has, up to the present, been a complete failure, and that if steel is to supplant wrought iron for such purposes some special compound will have to be adopted which should be more in accordance with the composition of high class Yorkshire iron. Referring to manganese steel, the President quoted from Mr. Hadfield's recent paper, read before the Institution of Civil Engineers. A steel containing 2·5 to 7·5 per cent. of manganese was as brittle as glass; but when the manganese was further increased up to 17 and 20 per cent. the transverse strength of the metal was about eight times greater than that of the metal containing the smaller quantity of manganese. When 12 to 14 per cent. of manganese are present, high carrying power and great elongation are secured. In one specimen containing 13·75 per cent. of manganese the breaking stress was 57·02 tons, and a permanent set was produced with 29½ tons with an elongation of 39·8 per cent., thus showing a power of endurance with great toughness unequalled by any class of metal called steel. This metal is toughened by heating it up to a white heat and plunging it into water of 72°F. Manganese steel has, however, the drawback of being extremely hard and difficult to machine.

The President next referred to cast iron. As the United Kingdom is the largest producer of pig iron in the world, individual members of the Institute might do great good by turning their attention to the subject of cast iron and some of its alloys, as a judicious selection of the ingredients of cast iron may lead to the production of compounds suitable for special purposes, in the same way as special kinds of steel are now made. Mr. Wood, of Middlesbrough, had informed the President that by a more careful selection of pig iron containing a definite amount of silicon, the transverse strength of cast iron has been increased by 11 per cent. Great importance is attached to the wise selection of materials for producing cast iron, since, without using some of the higher priced iron which is now considered necessary for certain purposes, it may thus be possible to obtain a suitable cast iron at a moderate cost.

The first paper read at the meeting on Wednesday, was by Mr. Thomas Turner, on

SILICON AND SULPHUR IN CAST IRON.

The author divided the subject into two parts, the first treating with laboratory experiments, and the second with observations on the products of blast furnaces. The laboratory experiments were made with the object of obtaining a rich silicide of iron from which silicon would crystallise out. A quantity of pig containing 10·2 per cent. of silicon was placed in small fragments in a covered clay crucible, and heated to nearly the melting point of cast iron. A quantity of sulphur was then introduced and the lid replaced. The addition of sulphur was repeated, and the temperature greatly raised until the whole metal was thoroughly melted; more sulphur was then added, the contents of the crucible being at the same time agitated by a stirrer. The lid was then replaced and the crucible allowed to cool. On examining the contents they were found to be divided into three distinct portions. At the bottom was a mass of metal weighing rather more than half of the whole material. Above this was found a number of balls resembling "sulphur balls," and the top layer consisted of powdery material not unlike coke in appearance, though it was covered in parts with a white film of fibrous silica. The metallic matter was very brittle, and when powdered in an iron mortar exhibited beautiful white scales, consisting of 10·93 per cent. of sulphur and 10·15 per cent. of silicon. The chemical composition of the metallic matters would thus be represented by the formula Fe_4SiS. Further chemical treatment showed that part of the sulphur originally present could be removed as sulphuretted hydrogen on treatment with hydrochloric acid, whilst the rest of the sulphur was left among the graphitic matter which was not attacked by the hydrochloric acid. The author then mixed 50grm. of silicon pig with 50grm. of the silicon-sulphur-iron, and melted it in a crucible. The button obtained weighed 89grm., and contained ·45 per cent. of sulphur and 10·78 per cent. of silicon. Thus by re-melting nine-tenths of the sulphur was

eliminated from the metal, much of it passing into the slag. On re-melting the silicon-sulphur-iron without any addition, the sulphur was reduced to 1·46 per cent., and the silicon increased to 13·45 per cent. The button was covered with a substance containing 22·14 per cent. of sulphur, 5·55 per cent. of silicon, and 72·27 per cent. of iron with a little manganese. It would thus appear that by merely re-heating, the original material was split up into two perfectly distinct bodies, one containing the greater part of the silicon, whilst the other was exceptionally rich in sulphur. From this result the author concluded that it is not possible for considerable amounts of sulphur and silicon to exist together in pig iron; in other words, that silicon has the power of expelling sulphur from cast iron. The author then referred to several previous experiments by M. Janoyer, Dr. Percy, Mr. A. R. Smith, and Mr. Weston, from which it appears that under certain conditions iron compounds may be obtained which are rich in sulphur and silicon, but the compounds are unstable. On melting, the silicon with the greater part of the iron remains, whilst most of the sulphur is eliminated, passing away in gaseous form or going into the slag. The author considers it probable that with a certain percentage of silicon there is a definite amount of sulphur which cannot be exceeded under given furnace conditions.

In the second part of the paper the author cited Sir I. Lowthian Bell's investigations, showing (1) that a low temperature favours the union of sulphur with iron; (2) that the composition of the slag greatly influences the absorption of sulphur. In attempting to commercially recover sulphur from alkali waste, the material was fused in a small blast furnace with oxide of iron, and a sulphide of iron containing 30 per cent. of sulphur was obtained at a moderate temperature; but when the temperature of the furnace rose above a certain point, white iron was produced instead of sulphide. Mr. E. Riley, when experimenting with Welsh iron, found that the sulphur increases as the richness decreases, and in each case the increase of sulphur was connected with a decrease of silicon, and upon the character of this twofold change the variation in richness chiefly depends. The author suggested that there may be a general law which governs the proportion of silicon and sulphur in cast iron, as long as the temperature and furnace conditions remain constant. This law can be represented by what the author calls a maximum sulphur curve of the general character shown in our illustration, the ordinates of which represent the percentage of silicon and sulphur. The general conclusions drawn by the author from his and other experiments are: (1) That high temperature tends to prevent the absorption of sulphur by iron; (2) that a slag rich in lime readily combines with sulphur; (3) that the amount of sulphur actually retained by the metal is influenced by the proportion of silicon; and if by any means an excessive amount of sulphur should be present, re-melting eliminates the excess.

The discussion on this paper was opened by Mr. Snelus, who did not agree with the author in his statement that the amount of sulphur actually retained by the metal was influenced by the proportion of silicon present. In the charge of a blast furnace they had an almost constant proportion of silicon and sulphur, and yet the product varied, and the variations were due to the reducing power of the gases—a circumstance which had been overlooked by the author. If the reducing power of the gases in the blast furnace is perfect, it has the effect of reducing silica to silicon, and lime to calcium. Sulphur had a strong affinity for calcium, and thus the sulphur would pass into the slag quite irrespective of the silicon present. The reducing power of the gases, which depended upon a variety of circumstances, would, however, also affect the amount of silicon passing into the slag.

M. Gautier pointed out that the author's theory of silicon expelling sulphur from iron was not new. Herr Ledebur, of Freiburg, had already directed attention to this fact in an attempt to explain the occurrence of blow holes in cast iron.

Sir Lowthian Bell thought that the operations carried on in the interior of a blast furnace were of so complicated and so varying a character that it was extremely difficult to draw any general conclusion from a few isolated experiments. He doubted that silica was reduced at all in that portion of the blast furnace where carbonic oxide was being formed, and they knew that the temperature necessary for the reduction of oxide of iron by carbonic oxide was low. It could be carried on at a red heat; but he was inclined to the belief that the last portion of oxygen removed from the ore and silica was not effected until the burden reached the hearth itself, where the temperature was much higher. He had arrived at this conclusion from observations of the composition of the gases in various parts of the blast furnace. He thought that the changes in silicon and sulphur to which the author had alluded were, in a great measure, due to temperature. They all knew that the lower the temperature of the furnace the less satisfactory would be the iron produced, and they invariably found that with a lower temperature they had a smaller quantity of silicon in the iron.

Mr. Edward Riley considered the temperature to be the whole gist of the question. White iron made in a charcoal furnace, and at a low temperature, contained more carbon than some of the most graphitic iron. If an iron was rich in silicon there would be little carbon present, and *vice versâ*, and he thought that the driving out of the sulphur was due more to the carbon than to the silicon. He considered that the regular way in which the sulphur decreases with an increase of silicon in the author's analyses was rather accidental. If they wished to get rid of sulphur, they must use a very heavy burden of lime, so heavy that the cinder would not melt unless some aluminous ore were mixed with the materials, and, in his opinion, the condition for getting rid of sulphur was a very high temperature and plenty of carbon.

Mr. Hatfield could not agree with the author that an iron high in silicon must be low in sulphur. His firm use for certain purposes iron containing from 8 to 12 per cent. of silicon, and according to the author, they should get it very free from sulphur; but, unfortunately, in practice they very often did not succeed in getting the sulphur lower than ·11 to ·15 per cent., and occasionally it was as high as ·32 per cent. They found that if they got the manganese above 1½ per cent. there was not much difficulty in reducing the sulphur, and with manganiferous alloys combined with silicon, they could get iron containing as little as ·03 to ·04 per cent. of sulphur. He had made some experiments in producing what he called "sulphur steel." The original steel had 1·44 per cent. of carbon, ·7 per cent. of silicon, ·07 per cent. of sulphur, ·07 per cent. of phosphorus, and ·86 per cent. of manganese. They added sulphur and produced metals containing ·9, 1·6, 2·28, and 5·24 per cent. of sulphur in which carbon and silicon had remained almost constant, but the manganese had been reduced to about half its former percentage.

Mr. Stead confirmed Mr. Turner's opinion regarding the power of silicon to prevent the absorption of sulphur. If they melted a pig high in silicon with coke containing

Digitized by Google

much sulphur, the resulting metal would contain very little sulphur; but if the pig were low in silicon, the metal would be high in sulphur. If the melting were done at a low temperature, they would in all cases get a metal high in sulphur. They all knew that as the temperature increased in the blast furnace the pig became richer in silicon and lower in sulphur, and they also knew that a slag rich in lime would absorb much sulphur.

Mr. Turner, in reply, thought that the difference of opinion between Mr. Snelus and himself was not so great as might at first sight appear. Mr. Snelus had dealt more particularly with the earlier stages of production, whilst his own observation referred to the later stages at the lower part of the blast furnace, where the metal was in contact with the slag. There was no doubt that a part of the sulphur in the slag was present in the form of sulphide of calcium, but another part might exist in a different shape. The point he wished to bring out in his paper was that when silicon and sulphur existed together in the pig, a portion of the sulphur would pass off and the silicon remain, but silicon would only eliminate a definite quantity of the sulphur.

The next paper read was by M. Ferd. Gautier, of Paris, on

The Melting in Cupola Furnaces of Wrought Iron or Steel Scrap Mixed with Ferro-Silicon.

As this paper was very short we reprint it in full.

Some twenty years ago experiments were made with a view to smelting wrought iron and steel scrap in cupola furnaces, and the connection of the name of Mr. G. Parry with such a process as applied to the manufacture of steel is tolerably well known. At that time the only known process for the elimination of phosphorus from pig iron was that of puddling, and it occurred to Mr. Parry that if he could only puddle moderately phosphoric pig iron, and melt this iron afterwards in a cupola, he could obtain a material suitable for the Bessemer process. The cupola process of melting wrought iron or steel scrap has many points in its favour. To begin with, the operation is accomplished more cheaply and more quickly than it would be in a reverberatory furnace; but on the other hand the temperature of the cupola is not high, and the conditions present for the reduction of silica and the introduction of carbon and silicon in the metal are not quite what they should be. The process yields an iron with practically no silicon, and with only 2 or 3 per cent. of carbon, the product being, indeed, white pig iron, which is not very fluid, which will hardly run out of the furnace, and which is as ill adapted for the Bessemer process as for foundry work. In order to overcome the absence of silicon in the metal thus obtained, Mr. Parry added about 50 per cent. of good hematite pig iron, high in silicon, which enabled him to reduce by about one-half what remained of the phosphorus. The cost of the process, however, interfered to prevent a successful employment of the cupola furnace, and its use having therefore been abandoned, the process has since been interesting only as a short chapter in the history of dephosphorisation. When we recollect that the cupola process was found to be very unsuitable for the melting of wrought iron and steel scrap, that the metal obtained thereby was white, that the 2 or 3 per cent. of carbon which it contained were, of course, combined with the iron, and that the iron was, therefore, too hard, and otherwise unsuitable for the foundry process, we can understand that Mr. Parry's experiment was not sufficiently encouraging to lead others to follow in the same direction, unless some new and important facts had, in the meantime, transpired to throw more light upon the matter. The introduction of ferro-silicon, which has been attended with a good deal of interest in metallurgical circles, has provided us with a new alloy, that has the power of converting a white pig into a grey one, and which is well adapted for the majority of foundry uses. In France it has been found that this power of precipitating the combined carbon of the white pig into the fine grained graphite is exhibited in an interesting way when a mixture of wrought iron or steel scrap is melted in a cupola, with a suitable addition of ferro-silicon. The first experiment in this direction was made in a shipbuilding establishment at Havre belonging to the Forges et Chantiers de la Méditerranée, when the charge consisted of—

Soft steel plate scrap	79
Ferro-silicon, 13 per cent.	21
	100

The percentage of silicon in the metal which was run out of the cupola was 2·60 per cent. One of the ingots obtained by the process could be hammered from 40mm. square to 35mm. square without any crack or flaw. This result is both novel and interesting as regards a metal containing about 2 per cent. of graphite and more than 2 per cent. of silicon. In France the drop trials adopted in the testing of artillery are as follow:—

Size of the square bars	30 × 30mm.
Distance between the supports	160 ,,
Weight of the ball	16 kilo.

The hammered cast ingot obtained in the process described supported twelve drops, commencing with 35cm., and was only broken at 1m. In another experiment, made at the works of Terre-Noire, the charge consisted of—

Steel scrap	77
Ferro-silicon, 9 per cent.	23
	100

In this case a square ingot of 30mm., submitted to the usual artillery test, was broken with the tenth fall of the hammer at 1m. 10mm., and was not hammered. If we consider that the ordinary pig iron for foundry purposes—as, for example, Scotch pig—when submitted to similar trials, usually breaks with an average fall of about 40cm., we can appreciate the increase of strength afforded in the case of the white pig by an addition of ferro-silicon. The softness of the metal obtained by the mixture of ferro-silicon and steel scrap was very considerable, and quite equal to that realised with white or light grey pig iron and ferro-silicon. This is undoubtedly due to the addition of silicon, and to the small proportion of carbon which remains in a combined state. The chief disadvantage of the employment of such a mixture of wrought iron and steel scrap with ferro-silicon appears to be that of its cost. Experiments, however, which I was enabled to make in a foundry near Paris have demonstrated that ordinary wrought iron scrap, and especially of the smallest kind (which may be had at a very low price), yields probably as good results as castings made with ordinary steel scrap. In this case grey metal is obtained with a close grain, and very sound castings, which are homogeneous and absolutely without blow holes; and if we consider that the resistance of the metal to shock is usually double that which is obtained with ordinary good cast iron, it appears to me that there is a special market for such castings, which might, at a comparatively low price, be substituted in many cases for the steel castings now generally employed.

Sir Henry Bessemer pointed out that experiments analogous to those of the author had been conducted at his own works some twenty-five years ago. At that time they manufactured large numbers of railway crossings and stamp heads, which were produced from a mixture of steel and cast or malleable iron. His metal was mixed with ordinary grey foundry iron, or with white iron, when intended for stamp heads. The mixture contained two parts of malleable metal and one part of the highly carburised iron, producing a close grain entirely free from blow holes. The stamp heads lasted three times as long as those made in the ordinary way. The speaker referred to this to show iron founders how, with the addition of a small converting plant, a most valuable metal could be produced.

Mr. Windsor Richards corrected a statement of the author regarding Mr. Parry, and said that this gentleman had no difficulty whatever in producing perfectly fluid pig. The speaker was associated at the time with Mr. Parry, and they intended to evade Sir Henry Bessemer's patent, but eventually they adopted his converter. They had no intention of dephosphorising by their process.

A letter from Mr. John Hardisty was then read by the Secretary, in which the writer stated that the utilisation of steel scrap in the cupola is not a new departure, as he himself had done this daily for two years. With small Bessemer converters, and a light blast through the bottom, there is difficulty in getting the blast sufficiently hot for the production of small castings, and as long as he used hematite pig iron it was only on rare occasions that he could get metal hot enough to cast without getting skulls in the ladle. The charge cooled towards the end during the combustion of the carbon, and therefore the writer desired to eliminate most of the carbon before commencing to blow, and for this purpose he used steel scrap and ferro-silicon containing 10 per cent. of silicon and 1·50 to 1·75 per cent. of carbon. The steel scrap contained from ·2 to ·4 per cent. of carbon, and consisted principally of the heads and runners from the foundry. The mixture that gave best results consisted of 19cwt. of steel scrap, 1cwt. of ferro-silicon, and 6cwt. of No. 3 hematite pig. The castings made from this mixture contained only ·2 per cent. of carbon. The metal showed a tensile strength of 27·8 tons, with an elongation of 36·6 per cent.

Mr. Turner pointed out that the mixing of steel scrap and pig iron was not the novelty in the author's paper, but the novelty consisted in the use of silicious iron. Many members would remember Stirling's patent of 1847 for the production of toughened cast iron, and there are many bridges now standing made of this metal. The method consisted in running grey cast iron upon wrought iron scrap, and then re-melting in a cupola; but the product was always more or less irregular.

Mr. Wood had occupied himself for many years with experiments intended to increase the strength of Cleveland iron by the addition of scrap steel in the cupola. With the present height of cupola it was, however, impossible at one operation to perfectly melt the steel so as to get a proper amalgamation. Even when charging the steel as turnings, they would upon planing the castings find some of the steel quite distinct from the rest of the metal.

M. Gautier in his reply said that there was a kind of dephosphorisation going on in his process, and he could make by it from Welsh or Northampton ores a reliable material. The difference between himself and Mr. Hardisty was that the latter gentleman blew his material in a small converter, whereas he did not blow at all except in the cupola where the ordinary horizontal tuyere was employed. The difficulties mentioned by Mr. Wood might be due to the surface of the scrap being oxidised. He had made castings from a mixture of 20 per cent. of wrought iron and steel scraps, 10 per cent. of ferro-silicon, and 70 per cent. of cast iron, which showed a tensile strength in the rough state varying from 13 to 15·4 tons.

The next paper read was by Mr. Herbert Eccles, on

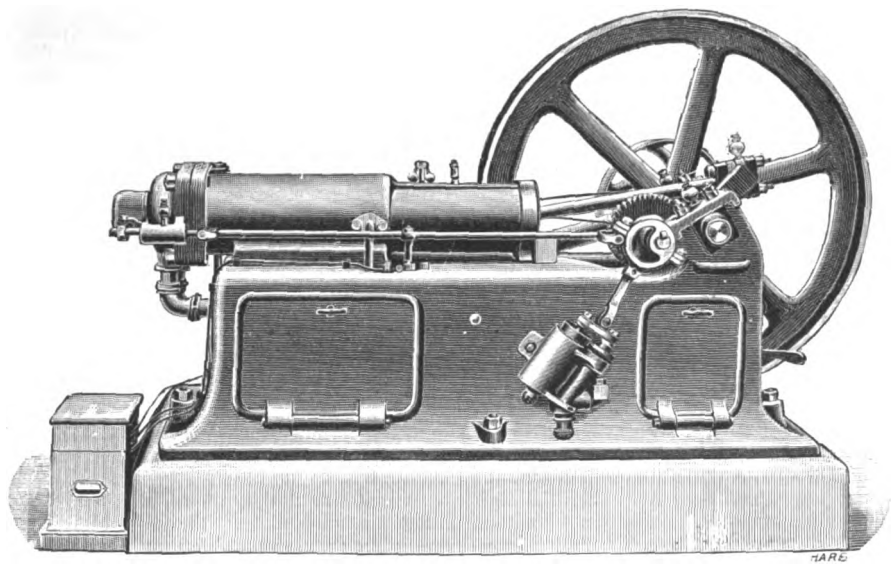
An Imperfection in Mild Steel Plates Considered Chemically.

We print this paper *in extenso* in another part of the present issue. Mr. James Riley, in opening the discussion, complimented the author on the clearness of the statements which he had brought forward; but if he would look up previous discussions on this subject, which took place at the Institute, he would find many of the difficulties alluded to. The liquation of the metalloids and other matters had been mentioned, but none of them thought it desirable to enlarge too much upon these difficulties in the early days of the manufacture of mild steel, as it would have alarmed their customers. In the early days, when smaller quantities of material were dealt with, the difficulties were, moreover, not so pronounced, but with the large and heavy plates made now absolute homogeneity is more difficult to obtain. He had, in a paper read at this Institute, pointed out that ingots should not be made thicker than necessary, in order that the particular failing dealt with by Mr. Eccles might be avoided.

Mr. Snelus thought that some of the faults of lamination mentioned by the author were simply due to overlap, a defect they were sometimes troubled with, especially when the plate had been rolled from a thick ingot. In other cases, however, there seemed to be no doubt that the failing was due to an excess of phosphorus in particular places. He agreed with Mr. Riley in his recommendation to keep the ingots as thin as was compatible with the size of the plate to be rolled. For this reason he always made plates from slab ingots, so as to prevent, as far as possible, the accumulation of liquated material in the centre of the ingot.

Mr. John Head, who agreed generally with the previous speakers, called attention to the fact that steel made in the ordinary way was always porous. Professor Bishop, when experimenting on the pressure at which microbes would be killed, had occasion to use a pump filled with mercury, with which he desired to produce a pressure of 11,000 atmospheres. He bought a pump from a very respectable firm in the North of England, but he found that the steel plunger was porous, and allowed the mercury to pass through. He then substituted another steel plunger made by a Sheffield firm, but with no better result. On the recommendation of the speaker he applied to Messrs. Osborne & Son, and a plunger made by that firm was perfectly successful, producing a pressure of 4000 atmospheres without any leakage of mercury. This plunger was made from steel heated by radiation, by which means a perfectly non-porous material can be obtained.

M. Gautier pointed out that when the cooling of Bessemer or Siemens-Martin ingots was too sudden, they found a hole in the centre; but with crucible steel made pot by pot, very slowly, this was not the case.



Mr. Harbord thought the size of the ingots from which the plates were rolled of great importance. From the analyses it appeared that the phosphorus had increased three times, so that if starting with ·06 of phosphorus, they might get in certain parts ·18. He had not found so great an increase in his own experiments with smaller ingots, although the increase was still considerable. Since, with the present demand for big plates, they could not use small ingots, he thought a possible remedy might be found in the employment of a very pure steel made from hematite iron. If they had ·01 of phosphorus in the side of the plate, they would at the worst have ·03 in the centre, and this was perfectly safe.

Mr. Le Neve Foster corroborated the statements of the author. In his experience he had repeatedly come across samples similar to those illustrated in the paper. He had succeeded in gradually obviating the defects by discarding one-third of the ingot at the top.

Mr. Stead said that owing to the defects described in the paper, the plate consisted in reality of three layers, two soft layers outside and a harder layer inside, which formed a very good arrangement for general work. The inner portion formed a kind of backbone to the whole mass.

Digitized by Google

THE PRIESTMAN PETROLEUM ENGINE.

The President had investigated the relative proportion of carbon in different parts of an ingot, and found it to vary between ·22 and ·78, which was more than one to three. He was pleased to hear from Mr. Stead that the plate produced by a thick ingot was really a kind of compound armour plate, with two outside tough sections and a rather harder interior. He thought that the disturbing elements should be kept down to a low measure, and that it might be desirable to increase the manganese, the proportion of which would not vary so much throughout the ingot, as it has nearly the same specific gravity as steel, and being slightly less fusible fixes itself more quickly. If they had a plate with a fair percentage of manganese and a small percentage of the other disturbing elements they would obtain a very uniform and reliable material.

The next paper read was by Mr. A. Wilson, on

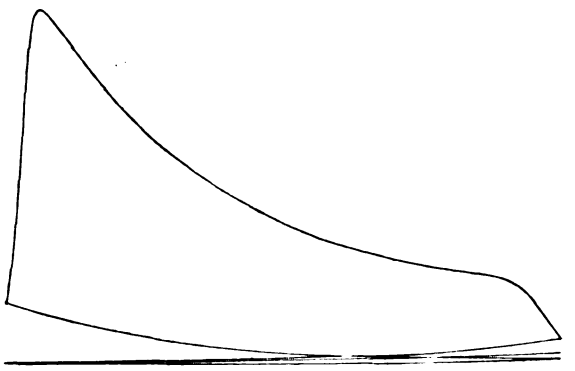
Water Gas as used for Metallurgical Purposes.

We shall reprint this paper in an early issue, and give, therefore, only a short abstract at present.

When steam is passed through red hot carbon, a mixture of gases is produced containing carbonic acid, carbonic oxide, and hydrogen. The proportion of carbonic acid decreases when the temperature rises, until at 1000°C. no carbonic acid at all is produced. Carbonic acid passed through carbon begins to be reduced to carbonic oxide at a temperature of 550°C. The whole reaction is therefore as follows: The decomposition of steam produces hydrogen and carbonic acid, and by continued contact with the incandescent coke, the carbonic acid is transformed into carbonic oxide. When carbonic oxide and steam are heated together above 600°C. there are produced carbonic acid and hydrogen. These chemical reactions are employed for the production of water gas. A mass of coke is heated by means of a blower, and during this time Siemens or generator gas is produced; the air supply is then shut off and the steam supply is turned on, when water gas is produced. The characteristic of this generator consists, therefore, in alternately producing Siemens gas and water gas. At the beginning of the second operation the gas coming from the generator is entirely free from carbonic acid and steam; but as the mass of combustible is cooled the gas acquires a larger quantity of one or the other, and in practice, the passage of 1100 litres of gas yields in the condenser 24 cub. cm. of water, which is equivalent to 4 per cent. by weight. As the fuel generally employed is small coke, leaving a considerable quantity of ash, it is desirable to construct the generating apparatus in such a way that large quantities of cinders may be easily withdrawn; and this problem has been solved by dispensing with a grate and surrounding the hearth with a conical water jacket, beneath which there is an annular space through which the air enters during the blowing operation, and through which water gas escapes in the next process. The slag is deposited on the conical surface of the fuel in a covering which extends up to the opening of the water ring, and the cinders are withdrawn by four cleaning doors. The cleaning out is done every six hours, and occupies from fifteen to thirty minutes. The water jacket acts in a certain sense as a regenerator heating the air supply, and cooling the water gas passing away. The first water gas plant successfully established in Europe was erected at the works of Messrs. Schulz, Knaudt, & Co., at Essen, and consisted of two generators, each capable of producing 10,000ft. of water gas per hour. At first the steam was highly superheated in a regenerator through which the hot gases were passed; but this practice was discontinued, owing to the rapid destruction of the bricks in the regenerator. The steam was then only heated to 500°C.; but, contrary to expectations, the consumption of fuel was not increased by this change. The next plant established was at the Witkowitz iron and steel works in Austria, where water gas is used for open hearth steel melting furnaces, for lighting the works, and for heating the billet furnaces. A similar plant has been erected at Hoerde, and at the Leeds Forge Company's works water gas plant for metallurgical purposes has also been erected. The author next touched upon the employment of water gas for lighting purposes. A flame of ordinary gas with the same speed of combustion has six times the surface of a flame of water gas, and consequently the temperature obtained by the latter is much higher. In using this gas for lighting, a comb, composed of little magnesia rods, is suspended in the flame, and raised to a state of white heat. The light possesses the advantages of absolute steadiness and purity, being superior to the electric glow light in whiteness, without having the bluish tint of the arc light. The author next referred to the most approved and economical types of generators which work with a mixture of air and steam and thus make a mixture of producer and water gas simultaneously. The cost is about the same as when producer gas and water gas are made separately, as before described. One ton of slack coal, at 5s. 6d. per ton, yields about 150,000ft. of producer gas, and one ton of inferior coke, at 6s. 3d. per ton, about 35,000 cub. ft. of pure water gas, and about 140,000 cub. ft. of generator gas, being at the rate of ·43d. per 1000 cub. ft. for fuel.

The discussion was opened by Mr. Morris, of the United States, who said that in his country water gas had been used for some years, but mostly for illuminating purposes. He was not aware of its being employed in America for metallurgical work. In his opinion gas firing was in every way an improvement upon the use of solid fuel, not only for the purposes mentioned in the paper, but also for the firing of steam boilers, where they would have a more perfect combustion, greater cleanliness, and less injury to the boiler plates than with the present system.

Mr. Walker, of Leeds, had seen the water gas plant put up by Mr. Sampson Fox, and testified to the excellent work done with it. The cost was also much lower than formerly, when the Leeds Corporation gas was used, although this, as they all knew, was very cheap.



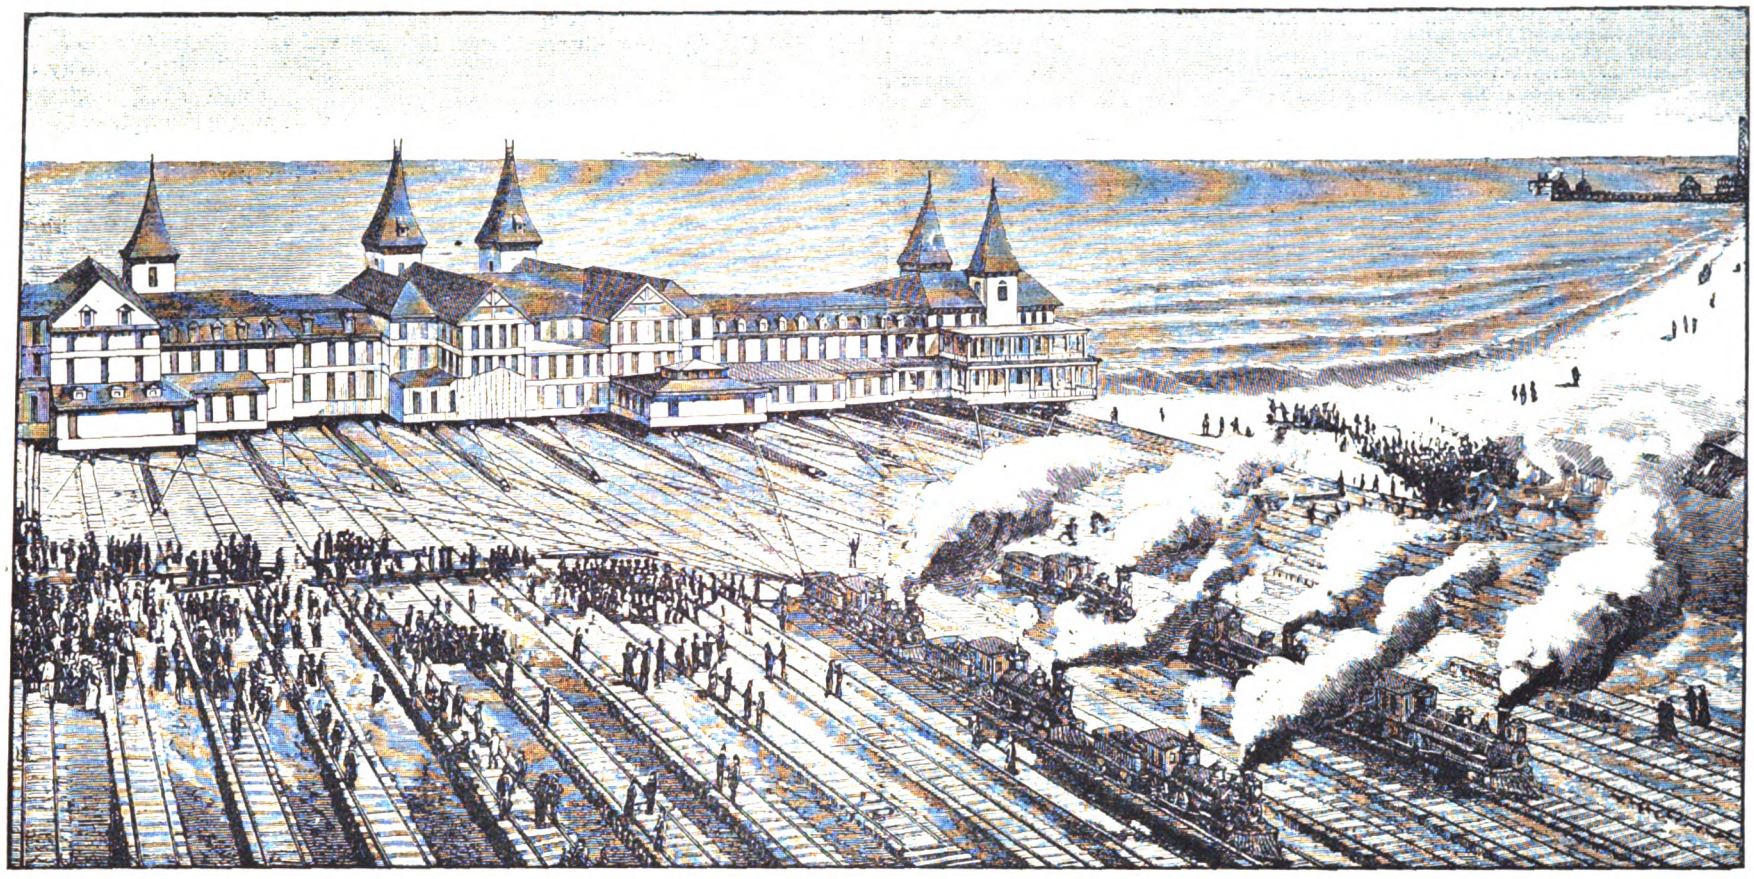
Sir I. Lowthian Bell thought that water gas could only be produced so cheaply because the fuel was taken at 6s. 3d. per ton; but if water gas were generally used, they would find some difficulty in procuring coke at this figure. He had seen the water gas plant at work in Essen and Frankfort, where it was used for welding in the manufacture of tubes, and he made some inquiries as to its application for lighting. On this subject he consulted Sir Frederick Siemens, Sir Douglas Galton, and others, and they all declared that, on account of the poisonous nature of carbonic oxide, the application for lighting purposes would be inadmissible. He was aware that, notwithstanding this danger, there were several cities in the United States lighted exclusively with water gas.

Mr. Stead had seen water gas employed in Mr. Wilson's house, both for lighting and heating purposes, with excellent results. The danger of carbonic oxide could easily be obviated by impregnating the gas with naphtha or some other compound which has a pungent smell, and any leakage would thus be immediately detected.

Mr. Wilson, in his reply, said that steam boilers are fired in this country, not by water gas itself, but by generator gas, which is a by-product in the manufacture of water gas. In America there were over three hundred cities or towns now lighted by water gas, and the proportion of fatal accidents was not greater than in the case of cities lighted by ordinary gas. For the purpose of detecting a leakage, the gas was impregnated with a small quantity of coal tar naphtha added whilst it passed through the purifiers.

THE PRIESTMAN PETROLEUM ENGINE.

It will perhaps be remembered that a year or two ago a new petroleum engine, known under the name of the Etève engine, was introduced into this country. It met, however, with little success, because necessitating the use of very light and volatile hydrocarbons, which for various reasons were objectionable. Not only are they difficult to obtain in certain localities, but if obtained, great precaution is required in storing them. There are also legal difficulties connected with the use of very light hydrocarbons. Fully recognising the defects of this engine, Messrs. Priestman Brothers, of Hull, have taken the matter up and have introduced various improvements, resulting finally in the production of an engine in which any heavy common petroleum may be used, whilst the mechanical details of the original Etève engine have been greatly simplified. The engine which we illustrate herewith, and which is now exhibited at their London offices, 73A, Queen Victoria-street, appears indeed to be far more simple than an ordinary gas engine. It is single acting, with an explosion at every second revolution, the charge being ignited by a spark from an induction coil worked by a single large bichromate cell. The base plate of the engine contains under the crank shaft a small closed tank, which holds about a day's supply of oil. This tank is filled from the outside by means of a pipe and bend, upon which is screwed an oil filter. The employment of an oil filter is of importance, because, as will be presently seen, the oil has to pass a very small orifice, which might become choked if there were any impurities present. At the other end of the bed plate under the cylinder is fixed a tank in which the oil is vaporised. From the first tank there lead two pipes into the vaporising tank, one for the oil and the other for the air. A combined air and water circulating pump is attached to the sides of the base plate, and driven from a lay shaft which also actuates an eccentric for



Indicator Diagram.

working the exhaust valve. The base plate of the engine stands upon a hollow pedestal of cast iron which forms the water tank, so that no external tank is required for the cooling water as in gas engines. The pump just mentioned serves to circulate the water through the jacket of the cylinder. The air pump delivers air into the top of the oil tank, and produces there a pressure of about 5lb. per square inch. The oil pipe dips nearly to the bottom of the tank, and by means of this pressure the oil is forced up the pipe and along it. At the end of the oil pipe within the vaporiser there is a very fine opening, through which the oil issues in a continuous and very fine jet. This jet is transformed into spray by an air jet, the supply of air being derived from the top of the oil tank, in which, as already mentioned, a pressure of 5lb. per square inch is kept up by the air pump. Thus within the vaporiser there is an atmosphere of air saturated with petroleum in suspension; the proportion of air to petroleum can be regulated by valves, so as to insure a proper strength of the explosive mixture. The petroleum vapour in the vaporiser is kept hot by the exhaust from the engine when at work; but to facilitate the starting, a small petroleum burner is provided under the vaporiser. This must be lighted a short time before starting. The charge

Digitized by Google

MOVING AN AMERICAN HOTEL.

is taken in at the outstroke of the piston and compressed at the next instroke. At the following outstroke it is fired, giving an impulse at every two revolutions. A valve in the inlet pipe prevents the propagation of the explosion back into the vaporiser. There is no slide valve properly speaking, but simply an exhaust valve which is worked by an eccentric. To the eccentric rod is attached, by means of an insulating handle, a metal knob, which describes a path somewhat resembling an ellipse, and is so placed that once in every revolution of the eccentric, that is to say, once in every second revolution of the crank, it bridges two metal springs which are insulated from each other and from the frame work of the engine, and which form the terminals of the primary circuit of the induction coil. By this means once every second revolution the induction coil is set going and the charge fired at the right moment. We have received from the makers a tracing of an indicator diagram taken from this engine, and which we publish herewith. The diagram is of an engine having an 8in. cylinder and 13in. stroke, and making 136 revolutions per minute. The scale of the diagram is 1in. to 80lb. We are informed that no lubrication is required for the cylinder, the petroleum vapour serving to keep the surfaces in good condition. The engine has been tested by Sir William Thomson, Mr. Boverton Redwood, Sir Samuel Canning, and by Messrs. Alabaster, Gatehouse, & Co., who have reported very favourably on its performance.

MOVING AN AMERICAN HOTEL.

Our American contemporary, the *Scientific American*, recently published illustrations of the method of moving the Brighton Beach Hotel, Coney Island, near New York, one of which we reproduce. The sandy beach on which the hotel was erected crumbled away under the action of the waves to such an extent that serious fears for the safety of the building were entertained, as the water made its way right under the structure, and threatened to carry it away. An adjoining building had to be moved several times, for which purpose it was cut into three pieces, which were removed separately. The same course was proposed for the hotel; but the cost of the undertaking in that shape was excessive. Buildings have been often moved before in America; but the operation we now describe is on an unusually large scale. Mr. J. L. Morrow and Mr. E. L. Langford finally devised the original and ingenious method of accomplishing the task, and Mr. Morrow was entrusted with the execution of the scheme. The undertaking was no small one, when we consider that the building is a wooden structure 465ft. long, 150ft. deep, and three storeys high, and that the estimated weight is about 5000 tons. It was proposed to support the building on freight cars, and move it by means of locomotives. To that end a series of parallel tracks were constructed, the gauge being about 4ft. 9in., with an average allowance of $\frac{3}{8}$in. play. Twenty-four of these lines were laid down, and 112 platform cars, supplied by the Iron Car Company, were placed on them for supporting the structure. The building was then raised by means of hydraulic jacks, in sections of 20ft. length; one 90-ton, three 60-ton, five 30-ton, and four 10-ton jacks being in operation. The sills were raised from the supporting posts, and the cars run under the building, each piece of which rested on two cars on adjacent tracks. The building was then lowered, and its weight kept the cars in place until the whole of the structure was supported on the cars. By means of blocks and ropes the cars were securely connected to six locomotives, arranged on two tracks, as shown in the illustration. On the 3rd April everything was ready, and the signal for the start was given, and the whole building moved forward. Only a short distance was traversed, when a thorough examination of the structure showed that everything worked perfectly. The hotel was then moved through a distance of 239ft., when the rails, sleepers, and stringers left between the house and the water were brought to the front and connected to the rest, after which the building traversed the whole distance of 495ft. without accident. The total weight moved is estimated at 6000 tons, of which 1000 tons was the estimated weight of the cars.

THE CYCLONE OIL BURNER.

The accompanying illustrations, for which we are indebted to our American contemporary the *Iron Age*, represent the cyclone oil burner manufactured by Messrs. L. Schutte & Co., Philadelphia, Pa., and intended for burning petroleum or any other liquid fuel. Fig. 1 shows a longitudinal section of the burner, while Fig. 2 illustrates the arrangement of the plant in connection with the burners. The oil is forced from a tank by means of a small steam pump through the pipe A (Fig. 1) into the burner, passes through the strainer F along the pipe C, and is discharged through a nozzle attached to C. This nozzle is provided with a screw blade round which the oil passes, thereby receiving a gyratory motion. By this means the oil issues from the nozzle in form of such fine spray as to resemble vapour. The air enters at B, and passes a screw blade similar to that fitted in the nozzle C, thereby receiving a gyratory motion resembling that of the oil. Oil and air are mixed in D, forming a cone which is ignited and produces the flame. E is a slide which regulates the air drawn in through an auxiliary inlet. Any dirt in the oil is retained by the

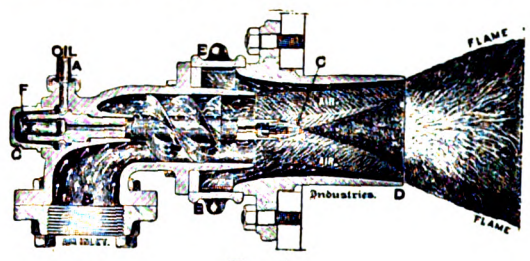


Fig. 1.

strainer F, which may be cleaned by taking off the cap shown in the illustration. This arrangement prevents the nozzle from getting choked by dirt. All parts of the burner are easily removed and cleaned. The oil ought to be supplied to the burner under a pressure of no less than 35lb. per square inch, which is most conveniently obtained by a small steam pump mentioned above. The

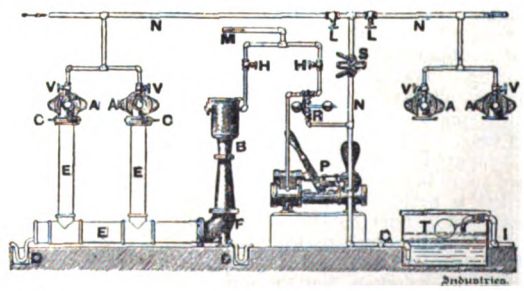

Fig. 2.

supply of oil is controlled by an automatic attachment to the steam valve. In Fig. 2, A A represents the burners, B the blower, C the blast gates, D D the drip pipes, E E the blast pipes, F the blower elbow, H H the steam valves, I the oil supply pipe, L the valves for regulating the oil supply, M the steam pipe, N the oil pressure pipe, P the steam pump, R the pressure regulator, S the duplex strainer, T the strainer tank, V the regulating valves.

FOREIGN INDUSTRIES.

(From our own Correspondents.)

PARIS, 15TH MAY, 1888.

THE IRON MARKET.—A great improvement is visible in the iron market here this week. The merchants, alarmed at the action threatened by the manufacturers of the North, have hastened to come to an understanding among themselves, and have put up their prices all round. The quotations now are: £6. 4s. for bars, £5. 16s. for joists, and £7. 12s. for common plates; old rails are sought at £3. 6s. Paris prices are now in accord with those of the provinces. Doubtless the effect upon the iron trade will be good, for many consumers hesitated to involve themselves in large contracts so long as there was an appearance of weakness in the market. In the Haute-Marne bars and special sections are in brisk demand, and prices are very firm. Wire is more inquired after, and wire nails are actively dealt in. There is briskness in the trade in bars and plates in the Ardennes, where the Paris merchants are now buying largely, with a view to render themselves less dependent on the Nord. The latest reports from the other centres of the iron industry agree in describing the situation as steadily improving.

THE METAL MARKET.—The collapse in tin has given a downward tendency to the metal market generally. The price of copper is maintained, because the syndicate buys up promptly every ton offered for sale; but this is a state of things that cannot long continue. Despite the enormous fall in tin, consumers refrain from buying, in the belief that prices have not yet touched bottom. In sympathy with the tin market, lead has receded a point, and spelter has further declined. The latest quotations are: Chili copper bars, £82; Banca tin, £126; lead, £13. 16s.; and Silesian spelter, £19. 4s. per ton delivered at Havre.

MARGARINE IN BUTTER.—The great event of the last meeting of the Société des Agriculteurs du Nord was the reading of a paper by M. Thibaut on a process for detecting margarine in butter, discovered by M. Dubernard, director of the Station Agronomique du Nord. Hitherto it has been impossible to detect the presence of margarine in butter, a circumstance which the adulterator has turned to good account. The simple process invented by M. Dubernard is as follows: Three grammes of the sample to be tested are put into a tube divided into equal parts, and heated in a sand bath to about 212°F. After the butter has been kept for a few seconds at this temperature, 5 cub. cm. of ammonia at 30° are added. The tube is then closed and vigorously shaken, after which it is replaced in the sand bath and kept for a short time at the previously mentioned temperature of 212°F. Under the influence of this temperature, the ammonia is driven off, producing a thick froth, which rises to a greater or less height in the tube according to the larger or smaller proportion of margarine present. In the case of pure butter, only a few small bubbles are formed on the surface of the liquid.

THE SUGAR BOUNTIES.—A deputation, headed by M. Mazurier, president of the syndicate of sugar manufacturers, waited, on Friday last, on M. Goblet to learn from him the actual state of the negotiations going on in London. The Minister of Foreign Affairs assured the members of the deputation that matters are not so far advanced as they have been reported in the newspapers to be, and that France has reserved to herself complete freedom of action pending a full investigation into the legislation on the subject existing in the several countries interested.

BERLIN, 14TH MAY, 1888.

THE COAL MARKET.—The negotiations which have been going on among the members of the Upper Silesian Coal Mining and Metallurgical Society, with a view to the restriction of the output of coal in that district, have never been regarded as likely to succeed; but the failure became apparent at the last general meeting of the Society. The principal cause of the failure is the fact that the two great fiscal collieries, which produce one-fourth of the total quantity of coal raised in Upper Silesia, refused to agree to any such proposal. The efforts which have been put forth to obtain a reduction in freight for the carriage of coal from this district to the northern provinces, in order to increase the sale of Silesian coal there, have also been futile. Meanwhile, the imports of English coal are augmenting. The prices at which contracts for forward delivery are at present being made, are such that no improvement in the coal trade is expected to take place this year. Contract prices not only show no improvement, as compared with those obtained last year, but in some cases there is even a decrease. For the Rhine district the market is better. The producers of coking coal in the Dortmund district have decided on an increase in price of 4d. per ton, to come into force at once.

THE IRON MARKET.—It is proposed to form a syndicate of fine sheet makers, but those interested anticipate great difficulty in the determination of the output of individual works. Should the syndicate be established, two sales bureaux will be formed in the Rhenish Westphalian district—one in Siegen and the other in Dortmund. The state of trade generally is satisfactory. The prices of forge and foundry pig have not changed since my last report. The export business at the present moment remains extremely quiet. The demand for bar iron for home consumption is very active. Boiler makers are exceedingly well employed, and heavy sheets are consequently in good request; fine sheets are also in good demand. It is stated that the reduced freight charges, granted last year by the Rhenish Westphalian State railways for the carriage of crude iron for export *vâ* the Dutch ports, will be discontinued on the 1st July next. The reason for the change lies in the loss of traffic receipts suffered by the Hanover railway administration. On the other hand, if the rates should again be raised to their former level, the iron masters of the Siegen district will find their export trade to be injured thereby. Reports from Upper Silesia state that some of the leading iron founders are going to renew their project of establishing a price convention for castings, which has been once before attempted, but had to be abandoned for want of support in the trade.

ENGINEERING WORKS IN SAXONY.—According to reports received from Chemnitz, the engineering trades there are at present in a satisfactory condition as regards the quantity of orders, but the prices obtainable are very low. The Saxon Machine Works (Hartmann) have orders on hand to the value of £100,000, and these are chiefly from abroad. The export trade to Japan is specially brisk. Large orders have recently been received from Russia, and from other countries, for knitting machinery, in which branch Chemnitz is specially efficient. Up to now work in this branch was scarce; but with the introduction of improved types, finding favour abroad, the export trade has now revived. Prices rule lowest in steam engines. Business in textile machinery and machine tools is fairly active. The Saxon Machine Works is well employed in the construction of locomotives, but prices are not very remunerative. This firm has recently taken up the construction of weaving looms on a large scale, and these machines are mostly disposed of in the German market. Last year embroidering machines were scarcely saleable, but now some little business is being done in this branch.

ELECTRIC TRACTION.—An electric tramway locomotive has been built by the Schwartzkopf Company of this town. It can exert a maximum tractive force of 8cwt., which is sufficient to haul on the Berlin lines three ordinary tram cars fully loaded, but without seats on the roof, or two tram cars with seats on the roof. The total weight of the locomotive when in service is 6½ tons. The current is supplied by a battery of sixty storage cells having a capacity of 320 ampère hours, and weighing 2 tons 4cwt. The motor is a disc dynamo, with double winding on the armature and two commutators. The windings can be put either in parallel or in series, so as to vary the speed and tractive force.

VIENNA, 14TH MAY, 1888.

THE IRON MARKET.—The general tendency of the iron market has remained unchanged during last week. Merchant bars, angles, and other rolled iron are in good demand on the part of agricultural engineering works, and business in building iron remains fairly active. The only articles in which there has been a slight reduction in price are black sheets; but the reduction was merely a local movement on the part of some works in Bohemia, resolved upon to meet a temporary competition from Germany. The fall in tin has not as yet had any influence upon other metals, and on the whole the characteristic features on the metal market are high prices and little business.

PROPOSED NEW IRON WORKS.—It is not generally known that ferro-manganese and spiegel were made in Austria before this industry took root in Germany, and the spathic ores of Styria and Carinthia were at one time extensively utilised for the manufacture of charcoal and spiegel. With the improvements in the process by which the smelting can be done by coke, the trade passed to the Rhine district, and now our Bessemer works are importing nearly the whole of their requirements of ferro-manganese from Germany. Under these circumstances the owners of works in Upper Carinthia still making spiegel with charcoal, which is becoming scarce, are now proposing to abandon them, and establish jointly a large works at Sava with Martin basic furnaces, by which the large stocks of Carinthian pig and old scrap iron now on hand might be utilised. The proposed site of these works is near the railway station, and water power of 2000 h.p. is available in that locality. The neighbourhood of Pontebba and Trieste would offer considerable facilities for export.

THE HUNGARIAN SMALL ARMS FACTORY.—This undertaking, which I have already mentioned in some of my previous letters, has at last been fairly floated. Subscriptions have been opened in Vienna and Berlin for 24,000 shares, representing a total nominal capital of 13,600,000fl. in silver, and bearing interest at 4 per cent., under the guarantee of the Austrian and Hungarian Governments. The Hungarian Government are assisting the undertaking by free grants of land, freedom from taxation, remission of import duties on machinery and materials required by the works, and by a reduction of tariffs over the State railways. They have also placed an order with the company for the supply of 180,000 Mannlicher repeating rifles, which must be completed by March, 1892. Amongst other orders already received is one for 1000 rifles, which must be delivered by the end of next year. It is estimated that when fully equipped the works will be able to turn out 250 rifles per working day.

ENGLISH CAPITAL IN AUSTRIAN PUBLIC WORKS.—The fact that German financiers are now regarding Austria as a profitable field for the employment of capital seems to have had the effect of directing the attention of English capitalists to this country. There are two undertakings which are now receiving the support of English money. One is the tin mines of Abertham, near Joachimsthal in the Erzgebirge, and the other is the regulation of the Iron Gates of the Danube. In the Berlin Treaty Austria undertook to remove this obstacle to navigation, and the work will have to be carried out by Hungary. The necessary plans have been prepared by Government engineers; but the estimates show that the cost of this undertaking would be far greater than the Hungarian Government could at present incur, and I learn that an English syndicate of capitalists has declared its willingness to undertake the work on certain conditions, the details of which have not yet transpired.

SULPHURIC ACID.—For some time past considerable activity has prevailed in the production of sulphuric acid, both imports and exports being on the increase. Twenty years ago the imports of sulphuric acid did not exceed 300 tons per annum, whilst the quantity exported amounted to about 450 tons. The impetus which this branch of trade has received since that time will be seen from the fact that the total quantity of sulphuric acid which was imported last year amounted to 2600 tons, whilst 2500 tons were exported. As a rule the exports do not materially exceed the imports; but in 1883, 1884, and 1887, the quantity imported was considerably greater than that exported. There is a great difference in the quality of the imported and exported article, the latter being three times more valuable than the former, which is mostly obtained from Prussian Silesia. Southern Germany and Russia receive the largest quantity of our exports.

BRUSSELS, 15TH MAY, 1888.

THE COAL MARKET.—There is considerable animation in the coal market, and an active demand for coal and coke for metallurgical purposes at unchanged prices. Coke dust is quoted at 7s. 2d., and large coke at 12s. per ton, whereas at this season last year only 9s. 2d. was paid for coke. The Charleroi section of the Association of Engineers has been giving its attention to the subject of the manufacture of coke from coal briquettes. M. Marsigny, of the Couillet Company, has given some interesting information on the subject. Patents have existed in England and Belgium for the last forty years in connection with the conversion of poor coal and anthracite, mixed with tar or resin, into coke. The idea, therefore, is not new; but the methods adopted at Châtelet present some novel features. The briquettes are piled on an iron plate, which is drawn into the furnace by means of a winch. The furnace door is then closed, and the plate is withdrawn through an aperture left for the purpose. The results hitherto obtained are not very encouraging, the coke thus produced being of much inferior quality to that made from rich coking coal.

THE IRON MARKET.—The announcement of the continuance of the iron syndicate for the current year has been accompanied by an increase of orders. A further rise is spoken of, with a base price of 96s. for rolled iron. There has been no alteration in the price of pig iron, and stocks are increasing, thus tending to relieve the market. Forge pig made in Belgium is quoted at 38s. 5d. to 40s., and English pig at 42s. 5d. Fine plates are 144s., and girders for home consumption 92s. per ton. Important contracts will be made to-morrow, the 16th, by the State railways, for railway material, including 750 tons of frogs of mild steel. It is not yet known whether offers will be received from abroad for the contract for 8000 tons of steel Goliath rails, which will have an important bearing on the prices of the tenders by Belgian manufacturers. The Ougrée Company have obtained an order for 700 tons of steel rails for the Amblève railway at 96s. per ton, which is considerably higher than the prices of the last State railway contracts. The Angleur Steel Works have made an arrangement with the Esperance Works of Liège for the construction of a new blast furnace near Seraing. The pig iron is to be used for the production of Thomas, or possibly, at a later period, of Bessemer steel. Further orders are expected for metal sleepers, the Grand Central Railway having reported very favourably upon them.

GLASS WORKS.—There is still a good demand; but, owing to excessive over-production, prices are falling, and the English market in particular is weak, owing to a want of combination among our manufacturers. It is, however, hoped that the plate glass syndicate will be maintained. Notwithstanding the condition of the industry, many of the old firms are extending their works, and the Anvelais Plate Glass Company have ordered a steam engine of 1000 h.p. for their new works from the Société de Couillet.

TEXTILES.—The markets show an improvement since my last report, both cottons and flax being in better demand. Some business has been done in Russian flax at fair prices. There is little doing in linens.

BELGIAN INDUSTRIES.—According to an official report there are in Belgium 4077 flour mills, 2574 breweries, 2249 cloth mills, 1333 potteries, 800 tanneries and leather works, 666 tobacco factories, 660 slate, stone, and marble works, 577 printing works, and 544 oil mills, making a total of 13,489. To these must be added collieries, metallurgical works, india-rubber factories, glass works, arms factories, and powder mills, bringing up the total of all industrial establishments, large and small, to 26,500.

ECONOMIC RAILWAYS.—The general meeting of the Economic Railway Company has been held, at which complaints were made regarding the delay in constructing certain lines, and the loss in working others. The total length of lines open for traffic in 1887 was 275 miles, and of lines in construction 65 miles; making a total of 340

Digitized by Google

miles. Since the formation of the company, up to the 31st of March, 1888, £330,727 have been spent on the permanent way, £237,277 on rolling stock, and £188,092 on buildings; making a total of £756,096. Demands for concessions for two hundred miles more of narrow gauge railways are now before the Government.

DÜSSELDORF, 14TH MAY, 1888.

THE COAL MARKET.—The coal trade affords the best possible evidence of the revival of industrial activity throughout the country. The market continues animated and strong for all classes of coal except house coal, which is never in very brisk demand at this season of the year. Prices, too, continue to advance. The Association of Gas Coal Owners have further raised their rates 3s. a 10-ton truck load. Coke, especially the qualities suitable for metallurgical purposes, is in strong demand. At a meeting of manufacturers at Bochum last week, representing 80 per cent. of the production of this locality, it was unanimously agreed to establish a new company, to be known as the "Aktiengesellschaft Westphalische Kohksvereinigung," to transact the business in coke through a common sales bureau, with a view to maintain the present satisfactory situation, The production of coal in the Dortmund mining district in the first quarter of the current year amounted to 8,085,318 tons, against 7,340,968 tons in the corresponding period of 1887, an increase of 10·14 per cent. The import trade, too, is very active. The total imports of coal and coke in the first quarter amounted to 1,538,676 tons, against 1,406,190 tons last year, an increase of 9·42 per cent. The exports show also a slight expansion, being 2,480,716 tons in the three months, against 2,439,405 tons last year, an increase of 1·70 per cent. The consignments of Westphalian coal to North Germany, where competition with English coal is extremely keen, steadily increase; but this gain is to be attributed rather to a larger consumption of coal than to any headway made against English competition.

THE IRON MARKET.—The iron market remains in its main features unchanged from what it was a week ago; but here and there some improvement is visible. The United States demand is weaker, and there is still the depressing influence of the low prices in England to take into account. More life has appeared in the business in crude iron. Forge pig is much more actively sought after, and the opinion gains ground that a further advance in prices will shortly take place. The market is animated and strong for spiegel pig. Thomas iron is in brisk demand, and foundry pig is being largely bought at prices considerably above the syndicate minimum. Most of the buying is now for delivery in the fourth quarter of the year, a circumstance which guarantees the maintenance of the prices of finished iron to the end of 1888. There is a steady business in bars; but merchants exhibit a reluctance to enter into important engagements. The foreign trade in bars and joists grows worse; transactions are few, and the prices obtained leave no profit. In the present state of our trade, Belgian competition cannot be successfully met. Manufacturers who work for the export trade claim some concession from the blast furnace owners; but the latter declare themselves unable to offer any reduction while ore and coke maintain their present rates. As far as coke is concerned, there is no prospect of lower prices. The home demand for hoops is reviving. Plates and sheets remain unaltered; the former are in brisk demand, and the latter are but little sought after. There is no change to report in the wire trade.

INTERNATIONAL GARDENERS' EXHIBITION.—An International Gardeners' Exhibition, to be held in Cologne in August next, will be of some industrial importance, inasmuch as green house and garden house structures, heating apparatus, tools, and other appliances used in gardening, will form the principal feature. To insure success to this undertaking the Government has instructed its representatives in Vienna, St. Petersburg, London, Rome, Constantinople, Brussels, The Hague, Copenhagen, Stockholm, Berne, Athens, and Washington, to invite manufacturers and others to exhibit at Cologne, and to afford all requisite facilities. The Minister of Agriculture has informed the General Committee that he is prepared to offer ten first class and ten second class silver medals, and twelve third class bronze medals, to stimulate competition.

LILLE, 15TH MAY, 1888.

TEXTILE MANUFACTURES.—The absence of spring weather has greatly restricted the spring trade in textile goods. This has been an unfortunate circumstance for the manufacturers who, judging from the apparent course of events at the beginning of the year, had accumulated stocks in anticipation of a brisk demand. The consequence now is a considerable depression. The turnover last week in linen goods shows a further decline, and compares unfavourably with the corresponding week of last year. In woollen goods, too, the latest report received from the Roubaix-Tourcoing district is a little disappointing. A few weeks ago it seemed that a genuine revival had set in; but on the whole, though a few classes of "fancy" have been in brisk demand, no further progress has been made. The causes of this discouraging state of trade are, a cold spring season and political insecurity. The jute manufacturers, as I reported some months ago, claimed from the Customs administration the collection of the same duty on full sacks imported in the foreign grain and seed trade as is levied on new sacks, their contention being that such sacks when emptied of their contents were equal to new, and were sold in the home market to the detriment of the native industry. Further it was asked that whenever an imported package was found to have a double covering, unnecessary for its protection, the outer covering should be held dutiable. By a ministerial decision it is now declared impossible for the Customs administration to deal with the matter under existing laws. It is, therefore, a question for the Legislature.

FLAX AND YARN MARKETS.—The flax market remains in a lifeless state. There is practically nothing doing either in home grown or Russian. Interest is for the time diverted to the growing crop, the development of which has been seriously retarded by the ungenial spring season. According to some authorities, but little permanent injury has yet been done; but much depends on the weather of the next two or three weeks. Business in yarns is quieter, and prices tend in favour of buyers. Jute yarns move heavily in the market, and sellers find themselves compelled to offer important concessions to induce customers to buy.

THE IRON MARKET.—If business in iron does not increase it certainly has suffered no abatement in the course of the last two or three weeks. Consumers have in many instances waited for the result of the contest between the manufacturers of this locality and the merchants of Paris. Now that the latter have been driven from their position, and practically compelled to raise their prices to the syndicate minimum, we may expect greater activity in the market. In the meantime, orders are sufficiently plentiful to keep manufacturers fully employed. As to the probable course of prices, an indication is afforded by the refusal of the coal owners to renew contracts at the old rates.

WINTERTHUR, 14TH MAY, 1888.

TECHNICAL EDUCATION.—The Polytechnic School at Zürich has long had the reputation of being one of the best Continental establishments for the education of engineers, architects, and chemists. A few years ago a new and very large chemical laboratory was added, and now there is in course of erection a still larger physical laboratory. Formerly the curriculum of the mechanical engineers' school contained only a very moderate amount of instruction in physics, and the head of the mechanical school was invariably an engineer. Now, however, this policy has been entirely changed. The head of the mechanical school is Professor Weber, a distinguished scientist in physics, but not a mechanical engineer, and under his auspices lessons in physical science occupy a very much larger share of the instruction supplied to those who wish to become mechanical engineers. The new laboratory will, when completed, have cost about 3,200,000fr., and will contain thirty-eight rooms where physical investigations will be carried on. Among these there will be four underground rooms, situated so low that the temperature in them will only vary by ·2°C. between summer and winter. These are intended for experiments which must be carried out at a constant temperature. In the basement of the laboratory will be installed various engines and dynamos, so that students will be able to carry out experiments on a large scale. No student will be allowed to compete for the diploma of mechanical engineer unless he has worked for at least forty days in the physical laboratory. Practical engineers here consider that this new departure in the training of mechanical engineers will not prove beneficial. They admit that a somewhat larger share of instruction in physics is desirable; but they consider that under the new programme the interests of practical engineering are likely to be injured by an overdose of theoretical physics.

MADRID, 14TH MAY, 1888.

THE ALTOS HORNOS COMPANY.—A dividend of 5 per cent. has been declared on last year's working of this company. These are the only works in Spain which roll Bessemer steel rails; but the quantity sold in 1887 was under 15,000 tons, although 70,000 tons to 80,000 tons could have been turned out. This is due to the fact that most of the railway lines are allowed to import rails duty free.

THE QUIROS IRON COMPANY.—The Quiros Iron Company, which was formed by a powerful syndicate of French capitalists, has, as I once mentioned before, proved a very disastrous concern, owing to want of judicious management; and after many years of useless attempts to keep the works going at a profit, they were closed more than a year ago. The property has now been sold to the Mieres Company for £30,000, the actual cost having been £250,000. The property includes very rich and extensive iron ore mines with ores of 48 per cent., which can be worked at a very low cost; coal mines, the actual value of which has not been ascertained; a narrow gauge railway, ten miles in length, forming a connection with the general system; and iron works at Trubia, with rolling mills for merchant bars. These works can make common iron bars cheaper than their competitors; but the small market offered by Spain having been secured by works established previously, they had a difficulty in competing.

NEW YORK, 5TH MAY, 1888.

THE IRON AND STEEL MARKETS.—The past week has been rather encouraging to the trade, as there is more disposition to buy, and consumers are now carrying very light supplies. Prices have not yet responded, however. A larger amount of business has been done in pig iron than for some time past, but at a low range of prices. There is not much chance of higher rates; but it is satisfactory to know that there is a bottom to the market, and that it is already within reach. Business has been very dull in manufactured iron, and there are no signs of improvement either in price or demand. The ordinary supply of orders is not nearly sufficient to keep mills running, while large orders are few and far between, and only obtainable by greatly reducing prices. Consequently, mills are running irregularly, and most unsatisfactorily to their owners. Prices are about 1·8c. to 1·9c. per lb. for best refined bars; but there is no uniformity, and orders can generally be placed at better rates. Manufacturers of steel rails are beginning to look forward for business to keep their mills busy after the middle of the year. All the Eastern and Southern roads have, so far, bought nearly as many rails as during the same period of last year; but the Western roads have hardly purchased over a quarter of last year's amounts. There are still many Western orders withheld, which must be placed before long. The next three months are likely to bring a heavier business than the corresponding period of last year. So far as can now be judged, the falling off in the demand for the year will amount to about 500,000 tons, which will about be equivalent to the falling off in track mileage from 13,000 to 8000, which is now probable. As the rail mills are now 850,000 tons behind last year, there has been a withholding of orders to the extent of about 350,000 tons, and most of these are likely to be placed in the next three months. There have been very light sales at old prices.

THE COAL MARKET.—An agreement has been come to among anthracite colliery owners to restrict the production to some extent. At present buyers take only small lots for present requirements, and there has been some accumulation of stocks.

THE METAL MARKET.—The copper market has been easier; but leading mining companies report that consumers are beginning to make inquiries, as stocks are getting low. Tin has been unsteady. Sales have amounted to about 100 tons. The decline in the iron trade is beginning to affect the tin plate trade. There has been little change in the price, but the tone is decidedly weaker. The lead market is still in the hands of speculators, and consumers are buying very little. Prices range from 4·65c. to 4·70c. per lb., with but little business done.

SHIPPING.—The question of free ships and bounties is again under discussion in Congress. A committee has reported adversely to the Lower House on the Bill for the payment of a bounty of 30 cents per 1000 miles per ton on vessels owned and built wholly in the United States and engaged in the foreign trade, and reported favourably on what is known as the Dunn Bill, which makes it lawful to buy vessels built wholly or in part in any foreign country, import them free of duty, and have them registered as United States vessels, and entitled to all the rights, and subject only to the same regulations as vessels built wholly in the United States. The same Bill allows materials to be imported in bond after January 1st, 1889, no duties being payable on the same if they are used in ship construction. The minority report will favour bounties and oppose free ships. It is not probable that any measure as sweeping as the free ship scheme can become law, as the bounty scheme is gaining more adherents each time the subject is agitated.

PHILADELPHIA, 5TH MAY, 1888.

THE IRON MARKET.—Pennsylvania irons have fallen a little, having been forced down by outside competition; but it is to be hoped that they have now reached their lowest limit. Prices are $20 to $20·50 per ton for No. 1 foundry, $18 to $19 for No. 2, and $16·50 to $17 for grey forge, with both supply and demand moderate.

ELECTRIC FEED WATER ALARM.—There has been for some time an electrical water level indicator in use in some of our mills, which is one of the most successful pieces of apparatus yet introduced for the purpose. A vertical vessel communicates by pipes above and below respectively with the steam and the water space of the boiler. In this vessel is a float attached to an arm which rises and falls with the water level in the boiler. To the spindle of the arm is fitted a pointer on the outside of the vessel, which moves over a graduated arc showing the level of water inside. To the same spindle is keyed a brass disc about 4in. in diameter, carrying on one side two pieces of wood set radially on opposite sides of the spindle. These pieces of wood can be set at any angle, and each serves to support a hermetically sealed glass tube having two platinum wires sealed in at one end, and containing a small quantity of mercury. According to the inclination of the tube, which depends on the water level in the boiler, the mercury is either at one end or the other, that is to say, establishing a circuit between the platinum wires or breaking it. Proper connections are made to an annunciator in the office, or wherever desired, and to a battery of about four Leclanche cells. When the water is at its normal level the mercury in both tubes is out of contact with the platinum wires, and no current passes; but if the water falls below a certain level, the mercury in one tube closes the circuit through the platinum wires in that tube, and causes the annunciator alarm to ring and a pointer on the annunciator to show "low water." In the same way, if the water gets above a certain level, the mercury in the other tube causes the annunciator alarm to ring and to show "high water."

AN IMPERFECTION IN MILD STEEL PLATES CONSIDERED CHEMICALLY.*

At the spring meeting of this Institute a year ago it may be remembered that a great deal was said against the careless treatment which steel plates often undergo during their process of manufacture and manipulation. Most of the failures of soft steel were attributed to gross carelessness on the part of the workmen, arising from ignorance of the properties of steel. Latterly, it is pleasing to note that these failures are less frequently heard of, as no doubt the manipulators exercise more care, and now treat the plates in a more rational manner. There may be, however, other imperfections in mild steel plates apart from rough treatment, such, for instance, as are produced by the unequal distribution of the metalloids, carbon, sulphur, and phosphorus. The irregular distribution of these elements in steel ingots has recently had considerable attention paid to it, and a more interesting treatment of the subject than occurs in Mr. Adamson's presidential address to the Manchester meeting last autumn could scarcely be found. Reference will again be made presently to this exposition. The reader of this paper begs to lay before the Institute the results of some observations and experiments which serve in tracing the physical and chemical effect of the unequal distribution of the metalloids upon mild steel plates themselves. It will be agreed at every steel works where the surveyors from Lloyd's, Board of

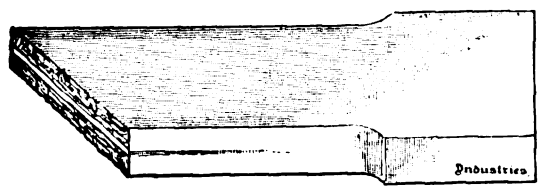

FIG. 1.

Trade, or the Admiralty have occasion to test samples of steel plates by the ordinary tensile stress, that they often meet with test pieces which after breaking present very defective fractures, and instead of the ordinary silky fracture throughout, there can sometimes be observed a white granular seam of varying thickness extending right across the sample; and it is possible to trace this seam on the outside of the polished test piece, especially after testing. (See Fig. 1.) A specimen like this behaves in a peculiar manner in the testing machine. It takes a comparatively greater amount of stress in a shorter time than ordinary sound steel, and the lever of the testing machine drops all at once, without any warning, after the maximum load has been applied; in other words, it behaves like steel short of ductility. The average mechanical tests of a large number of samples, compared with sound steel from the same cast, are as follow:—

	Good Sound Fracture (all Silky).	Faulty Fracture (with Granular Seams).
Tensile resistance per sq. in...	26·0 tons.	23·5 tons
Elongation, per cent. in 10in.	25·0 „	17·0 „

But even if the defective sample is fortunate enough to just reach the required tests, which is seldom the case, the custom of the surveyors is to reject the sample on account of bad fracture. If one of these faulty test pieces be immersed in dilute acid (preferably hydrochloric acid—1 acid to 50 water) for a few weeks, the acid being renewed from time to time, a very curious effect is produced. The interior granular seam just referred to is attacked more readily than the remainder of the metal, and if the action be sufficiently prolonged the specimen becomes almost severed in two. (See Fig. 2.) In this way twenty specimens were pickled, some having well defined seams, others with seams not so well marked, and others with good silky fracture; and the invariable result was that the interior was eaten away proportionately to the amount of the granular seam present. But even in the most silky fracture that could be obtained from a selection of thousands of samples, it was observed that the inside of the test piece was acted upon slightly more readily than the outside. The inference to be drawn from these simple experiments is, that a steel plate is chemically purer nearer the surfaces than in its interior; for we can compare the local action which causes the ready solution of the interior of the samples to the employment of impure zinc in a galvanic battery, in which case the zinc is very rapidly dissolved; the pure metal being, on the other hand, attacked only in proportion to the amount of galvanic action. With the view of ascertaining the difference of chemical composition, several test pieces were

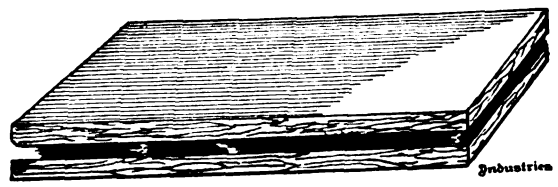

FIG. 2.

polished, in order to remove the outer skin, planings were taken from the outside and likewise from the inside or granular part, removed by a small cutting tool; the samples thus obtained were then subjected to a careful analysis, with the following results: Specimen 1.—Exhibiting well marked seam. Another portion of the same test piece, when pickled in acid, gave a well defined groove, as in Fig. 2.

	Inside (Granular Seam).		Outside (Silky Fracture).
Carbon	·160	.....	·115
Sulphur	·073	.....	·030
Silicon	trace	.....	trace
Phosphorus	·112	.....	·038
Manganese	·59	.....	·576

* Paper read by Mr. Herbert Eccles, F.C.S., before the Iron and Steel Institute, May 9th, 1888.

It will be noticed that the proportion of the impurities is widely different in the two parts of the plate, and corresponds with the solvent action of dilute acid. Specimen 2.—Sent for the purpose of experiment from a Sheffield steel works. Exhibiting broad irregular seams; pickled in acid, was attacked all over, but chiefly near the middle, as in Fig. 3.

	Inside (Granular Seam).		Outside (Silky Fracture).
Carbon	·155	.....	·105
Sulphur	·239	.....	·105
Silicon	trace	.....	trace
Phosphorus	·106	.....	·057
Manganese	·655	.....	·576

It will be noticed that the sulphur is very high in both parts, which may account for the irregular action of acid upon it. Specimen 3.—A test piece with a remarkably fine silky fracture throughout; the mechanical tests being very good:—

Tensile resistance	26 tons per square inch.
Elongation per cent. in 10in.	31 „ „

Pickled in acid, the inside was only slightly more readily affected than the outside, and the analyses show a less difference than in the previous instances:—

	Inside (Silky Fracture).		Outside (Silky Fracture).
Carbon	·135	.....	·115
Sulphur	·072	.....	·041
Silicon	trace	.....	trace
Phosphorus	·051	.....	·044
Manganese	·518	.....	·518

These are a few of the many analyses made, in all of which a seam across the sample corresponds to a layer of impure metal, *i.e.*, high in phosphorus, sulphur, and carbon; the manganese not being particularly affected. Silicon being almost absent, no conclusions could be deduced as to its behaviour. It now remains to be shown in what manner the impurities find their way to the centre of a steel plate, or, in other words, to account for the presence of the objectionable granular seam. Mr. Stubbs, of Manchester, first pointed

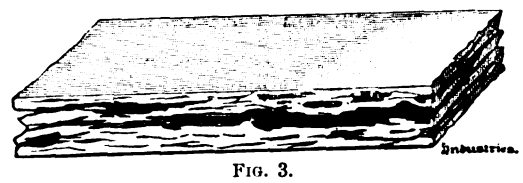

FIG. 3.

out the irregularity of the distribution of the elements in a steel ingot at a meeting of the Iron and Steel Institute held in 1881, and Mr. Snelus confirmed the observation by reading a paper describing a very exhaustive series of analyses of steel of moderate hard quality. Similar results are obtained in the case of soft steel, samples of which, taken from the inside and outside of an ingot, gave:—

	Centre of Ingot.		Outside.
Carbon	·14	.....	·11
Sulphur	·052	.....	·036
Silicon	·013	.....	·013
Phosphorus	·072	.....	·027
Manganese	·576	.....	·61

Quite recently a paper has been read by Colonel Maitland, before the Institution of Civil Engineers, in which he shows that the carbon varies very little close to the surfaces of an ingot, but that there is a funnel-shaped mass in the upper part where the carbon is doubled in quantity; between this accumulation and the bottom of the ingot there is a mass of metal in which the carbon is reduced considerably below the average. More recently still, Mr. Adamson, in his presidential address already

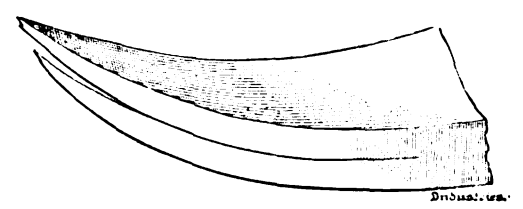

FIG. 4.

referred to, treats in a skilful manner of the conditions under which the separation of the metalloids takes place in a steel ingot, and has classified in an interesting table the difference in the fusibility, specific heat, and specific gravity of pure iron and the metalloids in question, showing clearly how the difference of these physical properties accounts for the variableness in composition observed in cast steel ingots. Probably most chemists would object to basing an explanation on the phenomenon of dissociation, *i.e.*, the severance of the bonds of union between steel and its metalloids taking place during cooling; for we have no reason to believe in any disunion of the alloys in steel in a chemical sense. Observation merely points to an accumulation of the alloys in a certain part of an ingot; and looked at in a mechanical light, the following explanation may suffice: The outside and bottom of an ingot, because they are in contact with cooling surfaces, solidify first, and in contracting cause the more fusible impurities to be squeezed towards the still fluid centre. At the same time, being specifically lighter, they have a tendency to ascend. We may consider steel to be pure iron, in which are dissolved carbide, sulphide, and phosphide of iron; and these compounds or alloys, as pointed out in Mr. Adamson's address, being much more fusible, and specifically lighter than iron itself, are thus to be found accumulated in the centre and top parts of an ingot. A similar phenomenon occurs, as shown by Dr. Ball, when a molten mixture of the metals copper, antimony, and lead is solidified. The copper and antimony form a definite alloy called regulus of Venus, which on solidifying ejects the greater part of the more fusible lead, driving it to the centre of the mass, so as to form a sharp line of demarcation, made particularly stiking by the difference in colour of the metals. We have another illustration furnished us by the investigations of geologists: It is generally accepted that when lavas pass from the fluid to the solid state, the component parts solidify in the order of their fusibility, especially when the lava has been subject to a dry fusion, and so unattended with complicated influences. Hence, in the interior of such rocks are to be found the most fusible minerals. Admitting that the middle of the ingot is the most impure, it seems only natural, after it has been hammered out and rolled, to find the impurities existing in a corresponding position in the plate; and if, from any reason, the determination of these impurities to the middle of the ingot should be abnormally increased, then we produce the objectionable seams observed in testing steel plates. Constant observation has shown that the larger the size of the ingots, and the more frequently are these seams found in the plates made from them. A shearing from the interior of a large steel plate, 1in. thick, on being sheared showed signs of lamination; in fact, all the pieces cut off had begun to split, and the

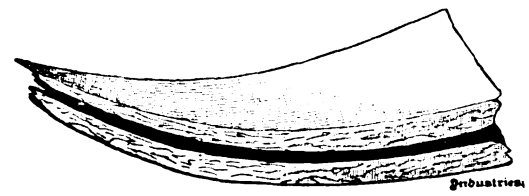

FIG. 5.

line of fracture could be traced along the entire edge of the shearing. (See Fig. 4.) The laminated surfaces, on being torn asunder, showed no signs of dirt whatever; on the contrary, they were perfectly bright. A piece of the shearing, about 4in. long, was pickled in dilute acid as before, when the interior became eaten away almost entirely, and the groove so formed was filled up with impure carbonaceous matter. (See Fig. 5.) Another portion of the shearing was analysed with the following results:—

	Inside, near Line of Fracture.		Outside.
Carbon	·24	.....	·15
Sulphur	·155	.....	·054
Silicon	·01	.....	·01
Phosphorus	·127	.....	·060
Manganese	·614	.....	·648

The explanation to account for the lamination seems obvious. The inside layer of the plate became so weakened by the accumulation of impurities that it was no longer able to withstand the work put upon it by shearing.

The conclusions sought to be drawn from this paper are, that a certain amount of care is required in selecting material for steel melting in order to minimise the above mentioned accumulation of impurities, and also to point out the necessity amongst chemists of a more careful method of taking samples. Samples taken from different parts of steel castings, blooms, rails, pigs, plates, and there is every reason to believe of pig iron also, may give provokingly varied results, and so bring discredit upon valuable analytical methods, whereas the fault lies solely in the samples themselves. It is submitted that a wider knowledge is still required in respect to the variableness in composition of iron and steel.

THE ITALIAN EXHIBITION.

THE Italian Exhibition at West Brompton was opened on Saturday last by the Lord Mayor, who attended in civic state. Judging from the number of visitors on the opening day, the Exhibition should prove a success commercially, notwithstanding the opposition which it will encounter from other similar attractions, in London and elsewhere, this year. The American Exhibition, which was held last year in the same grounds, was alone in the field, so far as London was concerned; but the fact that there are rivals on the present occasion has doubtless been advantageous in making it necessary for the management to do their utmost to make the Exhibition worth visiting. The American Exhibition was somewhat handicapped by a fear on the part of manufacturers and inventors in the United States that it had been got up for the sake of enabling their British rivals to steal ideas—a fear which was totally unfounded, but which had the result of curtailing the number of industrial exhibits. In the case of the Italian Exhibition, affairs have been different, as the Italian Government has looked upon it with favour, and given its assistance to the promoters. The King of Italy is among the list of patrons, while the Crown Prince is honorary president.

Those who are in the habit of attending exhibitions are not surprised at finding that at the date of opening the exhibits are not all ready. The only question considered as a rule is the degree of the state of incompleteness, and this year already, the Exhibitions at Brussels and Barcelona have been in a condition of chaos at the time fixed for opening. It is, therefore, not a matter of astonishment that the Italian Exhibition is not yet ready; but on the whole the progress has been satisfactory. The art sections are completely in order, and most of the exhibits in the main building, which constituted last year the only part of the American Exhibition proper, are in their places. The display here is mostly of art manufactures in their finished condition, such as elaborate wood carvings, furniture, Venetian glass, and majolica, and some excellent work in ornamental wrought iron by Signor Olivotti, of Venice.

An interesting exhibit has been sent by the Italian Ministry of Marine, consisting of about thirty models of vessels in the Italian navy, showing the progress which has been made since 1861. In addition to the vessels of the older types there are models in longitudinal section of the "Duilio" and "Dandolo," of 11,600 tons displacement and 7500 h.p., and of the "Italia" and "Lepanto," of 14,000 tons displacement and 18,000 h.p.

The following is the classification of exhibits which has been adopted:—

Class I., Vegetable products; II., Farm and dairy produce and preserved food; III., Wines, liqueurs, and other beverages, oils; IV., Minerals and metallurgy; V., Mechanical engineering, machinery, electricity; VI., Colonial and chemical products, processes connected with applied chemistry, drugs; VII., Textile products and fabrics; VIII., Paper, printing, bookbinding, &c.; IX., Furniture, decoration, carriages; X., Artistic industries (including porcelain, glass, mosaics, ceramics, jewellery, &c.); XI., Manufactures not otherwise classified; XII., Products of the sea, naval architecture, fisheries; XIII., Education, Italian institutions; XIV., Music and musical instruments; XV., Fine arts, sculpture, oil paintings, water colour drawings, etchings and engravings, gouaches, works in black and white, architecture, carvings, archæology, photographs, and chromo-lithographs.

Some new buildings have been erected in the western part of the grounds, but the exhibits were not in readiness on the opening day; and as these sections comprise metallurgy, engineering, industrial manufactures, and all those subjects which will prove of most interest to our readers, we shall have to defer a detailed notice of the Exhibition until such time as they shall have been put into order.

We understand that the House-to-House Light Supply Company, Limited, London, have ordered for their first central station at West Brompton three horizontal compound steam engines, from Messrs. John Fowler & Co.; and three water tube steam boilers, with water heaters and feed pumps, from the Babcock & Wilcox Company.

We have just received from Messrs. Mather & Platt, engineers, Salford Iron Works, Manchester, two catalogues of electric light machinery, containing illustrations and particulars of their well known "Edison-Hopkinson" and "Manchester" dynamos. The illustrations are neatly executed and the information given is very complete, containing particulars of tests as to efficiency and durability, the description and output of the different sizes and types, and the prices of both dynamos.

North-East Coast Institution of Engineers and Shipbuilders.—The closing business meeting of the fourth session was held in the Lecture Hall of the Literary and Philosophical Society, Newcastle-on-Tyne, on Wednesday evening, the 9th inst., Mr. W. Theodore Doxford, president, in the chair. A discussion took place upon Mr. Alex. Taylor's paper on the "Construction of Pontoon and Floating Dry Docks," after which the following general business of the Institution was taken up: It was agreed to increase the subscriptions of the junior members, and if the funds would permit, to open central offices for the Institution in Newcastle-on-Tyne, and to found a reference library for the use of the members. It was also suggested that as the number of members who reside in the Hartlepools and Tees ports had considerably increased, the Institution should endeavour to hold some of its meetings in that vicinity. The President intimated that the committee appointed to formulate a rule for the horse power of marine engines had, after two years' work, presented its report to the Council, and that the report should be printed in the present volume of the Transactions, and copies of it should be also laid before the kindred institutions and societies of the kingdom. Arrangements were also being made for the Institution to pay a visit to the Forth Bridge works, which visit would likely take place during the last week in July next.. The President then announced the result of the ballot to fill up the vacancies in the Council for the ensuing year.

Liverpool Engineering Society.—The last meeting of the present session of this Society was held on the 9th inst., Mr. C. H. Darbishire, president, in the chair. A communication was read by the secretary from Mr. E. Gobert on the paper read at the previous meeting by Mr. Bamford, on air brakes. Mr. Gobert said the question now was which kind of brakes, vacuum or compressed air, was most advantageous. When they considered the question, both from a practical and theoretical point of view, its solution must decidedly be in favour of the air pressure brakes, the most perfect and efficient of this class being the Westinghouse automatic brake, both in its usual form and the latest addition it has recently received from the inventor himself. The automatic brake, in its present form, might be a very serviceable brake on short trains, as used in this country; but it was entirely unsuitable for long trains, such as it is the practice to run on the Continent and in America. It was not known yet whether the automatic vacuum brake is affected by intense cold, as the old vacuum brake used to be; but intense cold had no effect on the Westinghouse brake, as the writer had occasion to witness some two years ago, whilst he was in Transylvania, where the winter is generally more severe than it is in this country. It might, he said, be asserted with fairness that the Westinghouse brake had attained finality in the latest type produced by its inventor. An interesting discussion followed. The following officers were then elected for the ensuing year: President, Mr. C. H. Darbishire; vice-presidents, Messrs. J. J. Potts and H. H. West; honorary secretary, Mr. J. H. T. Turner; hon. treasurer, Mr. O. S. Pilkington; hon. librarian, Mr. J. A. Brodie. During the recess it is proposed that the members shall visit the Forth Bridge, the Vrynwy Water Works, the Preston Dock Works, and the Weaver Navigation Works.

Notices of Meetings.

NEXT WEEK.

Royal Institution of Great Britain.—Tuesday, 22nd May, 3 p.m. Lecture on "Conventions and Conventionality in Art," by Mr. S. Colvin.—Thursday, 24th May, 3 p.m. Lecture on "The Growth and Sculpture of the Alps," by Professor T. G. Bonney.

Society of Telegraph Engineers and Electricians.—Thursday, 24th May, 8 p.m. Extraordinary general meeting. Paper to be read on "His New Standard and Inspectional Electric Measuring Instruments," by Sir Wm. Thomson, LL.D., F.R.S.

Royal United Service Institution.—Friday, 25th May, 3 p.m. Paper to be read on "The Equipment and Transport of Modern Armies," by Colonel H. M. Hozier.

PRICES CURRENT, 17th May.

Quotations at per ton, unless otherwise specified.

Messrs. Carrick & Brockbank, Manchester, report as follows:—

Copper.—Since our last, quotations for Chili spot parcels have ruled from £81 to £83 per ton, and three months from £78. 10s. to £75. 10s., with a fair business at intermediate prices. The increasing difference between spot and three months copper attracts much attention, as it indicates a want of confidence in the ability of the French syndicate. It is probable, however, that there may be steady buying of these forward parcels, and that prices will be maintained for a time, as it is too early to look for a collapse in the great speculation. The copper trade meanwhile continues inactive, the demand being very small, and most of the manufacturers being very short of work.

Spelter continues to droop; warrants quoted £16. 10s. to £16. 15s. per ton.

Tin has been active during the past few days, and prices have somewhat recovered. Straits quoted £85 to £85. 2s. 6d. per ton for sharp cash; £85 to £85. 10s. three months. English is also in good demand at advancing prices, being extremely scarce for early delivery.

Lead is weaker. Spanish quoted £12. 10s. to £12. 15s. per ton. Demand sluggish.

CARRON PIG IRON—BRAND "CARRON."

Present prices of "Carron" pig iron are as follow:—

Gloucestershire Engineering Society.—On the 1st inst., the members of the newly formed Gloucestershire Engineering Society met in the theatre of the Science and Art Schools, Gloucester, to hear the first contribution to their Proceedings in the shape of a lecture by Dr. Ryan, of the Bristol University College, delivered by desire of the Council. In a discourse of over two hours duration, the lecturer dealt with some of the more interesting features of modern high speed engines and current marine engineering practice. He showed how electrical engineering had reacted on steam engineering, and given rise to the numerous very ingenious forms of high speed engines. Many of these were illustrated by lantern slide photographs, and particular commendation was given to the rotary engine of Mr. John Fielding, a model of which was on the table. Compassionate reference was made to the confiding people who, without presuming to hamper it by mechanical or other conditions, looked to electricity to fulfil every industrial need, and in some mysterious way to supplant every form of motor. The impulse which electric lighting had given to steam engineering, and the magnificent way in which inventors and manufacturers had responded to it, emphasised the vanity of the hope of those who expected a pan-electrical millennium. The lecturer went on to trace the rise and progress of the triple expansion engine, both for marine and land purposes. He commented on the unparalleled uniformity of opinion amongst marine engineers with regard to its merits. The battle between "simple" and "compound" engines was waged on nearly equal terms for over a decade, and now the triple expansion engine had unmistakably beaten the victor without straining a crank pin or starting a bolt. Curiously enough, all makers alleged an economy of just 25 per cent. for the new over the old type of engine. It was hardly ever more, and seldom less. The lecturer quoted the case of the "Wells City" steamship, formerly belonging to the firm of Chas. Hill & Sons, Bristol. Their consulting engineer, Mr. John Scott, had furnished him with particulars of the performances of the triple expansion engines of the "Wells City" and of the twin cylinder engines of a sister ship, the "Jersey City." The former had certainly realised an economy of 25½ per cent. in the coal bill over the latter. Dr. Ryan attributed 20 per cent. of this to the intrinsic merits of the higher pressure of the steam and the greater expansion, 4 per cent. to accidental advantage in the case of the boilers, and 1½ per cent. to contingent advantage in screw efficiency. Mr. J. J. Seekings, of Gloucester, occupied the chair, in the unavoidable absence of Mr. Jas. Platt, the president.

HOME INDUSTRIES.

MANCHESTER, 17TH MAY, 1888.

THE IRON TRADE.—The condition of business in all branches of this trade continues to be very dull. The fall in the price of Scotch pig iron, and the increase of public stocks, tend to unsettle the market and to prevent free buying. However, there is probably more iron being used in this district than at any previous time; but it is bought in a number of small lots, instead of in large quantities as formerly. Scotch pig iron is now in store to the extent of 978,000 tons, as against 942,800 tons in the early part of January; Middlesbrough stocks also show an increase of 35,000 tons, while the hematite stored is about 3000 tons less. In twelve months the stock of Scotch pig has increased about 107,000 tons, and of hematite 29,000 tons, while Middlesbrough stocks have decreased 24,000 tons. The total stocks are now close on 1,500,000 tons. There is very little constructional work going on, and wrought iron does not show any improvement; as specifications are being worked off, prices tend to diminish. It appears probable that local bars will again touch the low rates of last year, which will leave no margin of profit. The great difficulty experienced in the bar iron trade is to obtain specifications for iron already sold under contract. Steel bars during the past few weeks have been extensively sold at prices ranging from £6. 12s. 6d. per ton delivered, less 2½ per cent., which is a very indifferent price. Boiler plates of steel are also in good request at prices which are tending downwards, there being already a fall of 7s. 6d. per ton. This business is now an extensive one, but all the orders are keenly competed for.

THE ENGINEERING TRADES.—There is little new to report of this business. Engineers continue to obtain a fair quantity of work, consisting mostly of repairs and replacements. The same remark applies to millwrights, but in both branches business is checked by the prospect of a strike in Oldham. Boiler makers continue to be busy, and bridge builders are also well employed. The improvement which has been recently reported in the locomotive business is hardly maintained, and the number of inquiries has considerably decreased. Tool makers are slowly improving their condition, and there is much more being done than there was a few months back; the orders coming forward are very general in character. Textile machinists are almost without exception actively employed, and in some cases will not give a promise of delivery for some months ahead. Several large foreign orders have been recently placed, and the prospects of this trade are favourable in the extreme. The prices which are being obtained are very closely cut, but it is quite certain that profits are being made; one of the few limited companies engaged in this business has recently paid a very good dividend, besides carrying over a large sum to reserve. Gas engineers are fairly employed, although, from the number of engines now in the market, the competition is becoming severe. Makers of electrical machinery are also well supplied with orders.

LONDON, 17TH MAY, 1888.

THE MONEY MARKET.—The rates for the loan of money began to fall almost as soon as the market felt the effect of the rise in the Bank rate. The action of the Directors of the Bank of England has reassured the outside lenders, who consequently make their rates more easy. Gold will at once begin to come back from the North, and there are shipments on their way which will help to strengthen the depleted reserve. There is no doubt that the delay in raising the Bank rate created a slight panic; for with every Continental centre accumulating gold, it was not very safe to leave the London market at the mercy of the whole world. The Stock Market is again dull, the approach of the Whitsuntide holiday helping to depress business. Home railway stocks, which had begun to move upwards, have come to a standstill again, which is simply due to absence of business in the market. This, in face of the favourable traffic returns, is rather disappointing, as the prospects of nearly all the lines are such as to justify a general rise. Great Western stocks, however, are in favour, as the receipts from the beginning of the year have been exceptionally good. American stocks are lifeless. The most popular form of industrial investment just now is in brewery companies, which are unquestionably profitable.

COMPANIES.—There is no diminution in the number of new companies which are floated, or which are attempted to be floated. The aggregate capital of the companies registered during March amounted to £17,804,400; against this we have in April 416 companies, with the enormous aggregate capital of £121,658,314. The following have been registered since our last report: Bell's Asbestos Company, Limited, with a capital of £200,000; the Engineering and Railway Contracts Syndicate, Limited, with a capital of £1,000,000; the Chandor Petroleum Gas Candle Company, Limited, with a capital of £100,000 (an illustrated description of the petroleum gas candle will be found in *Industries* Vol. III., page 458); the Buenos Ayres and Talcahuano Great Inter-Oceanic Railway Company, Limited, with a capital of £5,000,000; the Inter-Oceanic Railway of Mexico (Acapulco to Vera Cruz), Limited, with a capital of £2,500,000; the Anglo-Continental Aluminium Company, Limited, with a capital of £1,000,000; Leach, Neal, & Co., Limited, with a capital of £60,000, to carry on business as colour manufacturers at the Driffield Works, Derby; the Water Proof Materials Company, Limited, with a capital of £250,000; the Albion Engineering and Contract Company, Limited, with a capital of £50,000; the Miners' Safety Explosives Company, Limited, with a capital of £200,000; the Hercules Dynamite and Explosives Company, Limited, with a capital of £100,000; John Spencer & Sons, Limited, with a capital of £400,000, to carry on business as steel manufacturers, &c.; the Lawrence Light, Heat, and Power Company of London, Limited, with a capital of £250,000; the Cape Copper Company, Limited, with a capital of £600,000; the Crystal Creek Company, Limited, with a capital of £100,000, to acquire mines in Swaziland; the Gwndwn Hill Gold Mining Company, Limited (Wales), with a capital of £60,000; the Anglo-Continental Exploration Company, Limited, with a capital of £41,000; the Great Sheba Gold Mine, Limited (South Africa), with a capital of £120,000; Grinton Mining and Smelting Company, with a capital of £50,000; Mount Wilson Gold Gravels, Limited (United States), with a capital of £120,000; the Empress Mines, Limited (United States), with a capital of £300,000; the Gold Fields of Siam, Limited, with a capital of £250,000; the Storm Cloud Gold Mines, Limited (Arizona), with a capital of £100,000; the Carnarvonshire Freehold Copper Mining Company, Limited, with a capital of £25,000; the Quintera Mining Company, Limited (Mexico), with a capital of £40,000; and the South Green Harth and Nether Harth Lead Mines, Limited (Westmorland), with a capital of £30,000. The Government is unable to state when the Bill for the Amendment of the Law of Limited Liability will be introduced into the House of Lords, but it is in a forward state.

EXHIBITION OF LIFE SAVING APPARATUS.—At the Alexandra Palace, which has been re-opened in spite of the misfortunes which have attended previous efforts, there is a small exhibition of life saving apparatus, and it is announced that additional exhibits will be received until the end of June.

RAILWAYS.—The gross receipts of the twenty-three principal railways in the United Kingdom for the week ending 6th May amounted to £1,240,321 on 15,852 miles, as compared with £1,212,018 in the corresponding period of 1887, when the mileage was 15,728¾ miles. An increase is thus shown in the mileage of 123¼ miles or 0·7 per cent., and in the receipts of £28,303 or 2·3 per cent.—The success of the Westinghouse brake is leading to its increased adoption both on the Continent and at home, and the London, Chatham, and Dover Railway Company have now introduced it upon their system.

THE NAVY.—The Admiralty has sold out of the service the following old and obsolete unarmoured vessels of war in the reserve at Chatham: The "Juno," 3316 tons, 1381 h.p., screw corvette; the "Sappho," 894 tons, 884 h.p., composite sloop; the "Modeste," 1934 tons, 2177 h.p., screw corvette; and two mortar vessels. An unprotected composite sloop, the "Nymphe," has lately been floated out of dock at Portsmouth. This is a sister vessel of the "Buzzard" and "Daphne," and is slightly larger than the gunboats of the "Bird" type, and rather smaller than the protected cruisers of the B class. She will have two sets of horizontal triple expansion engines each of 1000 i.h.p., which are being made by the Greenock Foundry Company. A composite screw gunboat, the "Partridge," has been launched at Devonport. She is 165ft. long by 30ft. broad, and her mean draught when ready for sea will be about 11ft. 4in.

TELEGRAPHS.—In the course of an examination before the Select Committee of the House of Commons on Revenue Department Estimates, Mr. Patey, the Permanent Secretary to the Telegraph Department of the General Post office, stated that the annual cost of the extension of telegraph lines throughout the country was about £100,000. The telegraph lines now occupied nearly all the main roads of the country, and in a few years any extension of the system would have to be effected by means of underground cables, not in substitution of the overhead lines, but in addition to them. He stated that the cost of the underground system was about ten times that of the overground, amounting to between £350 and £400 per mile.

GLASGOW, 17TH MAY, 1888.

THE SUBWAY AND CENTRAL RAILWAY BILLS.—This project has been again defeated, the Select Committee of the House of Lords having found the preamble of the Bill not proved. It is improbable that the scheme will be brought forward again, especially if the Central Railway Bill passes this session. Should the Central Bill not succeed in getting through, the Subway scheme may perhaps come forward under another form. The Central Railway Bill has been before the Lords' Committee for some days, and a large number of witnesses have been examined. It now stands adjourned until the 6th June. The North British Railway Company are among the opponents of the measure. This is very natural, since one of the objects of the Bill is to obtain access for the Caledonian Railway Company to Queen's Dock, in order to communicate with the very large shipping industry there. Hitherto the North British Railway alone has been in the position of serving the docks. Among the points brought out in the evidence, there was the fact that a large number of vessels, after loading general cargo in Queen's Dock, went for coal to the general terminus at the south side, which is largely employed by the Caledonian Railway. It was originally intended that the Central Railway should be promoted by a separate company, consisting of a few responsible individuals, very much in the same way as in the case of the Central District Railway promoted by Messrs. Baird, and then handed over to the North British Railway Company. But after the initial steps had been taken, the Caledonian Railway Company concluded to promote the Bill in their own name, arranged with the original promoters to become responsible for the costs, and then applied to Parliament for suspension of the standing orders, so that their name should appear as promoters of the Bill. This alteration was, however, refused. In addition to this initial trouble, there has been another hitch about the payment of the deposit required by the standing orders, some £61,000. It was announced on Monday that this deposit had been paid into bank in Glasgow, so that probably the technical difficulties of the measure are over, and it may now be discussed on its merits. The progress of the measure is watched with much interest in Glasgow, as, if it passes, the railway will affect many interests, and considerably increase the transit facilities both for passengers and goods.

THE EXHIBITION.—The Exhibition bids fair to become a phenomenal financial success. The demand for season tickets last week was so greatly in excess of anticipation that the supply was entirely exhausted. It is understood that nearly 40,000 season tickets have been sold. The number of entrants also to the Exhibition has exceeded the most sanguine expectations. Excluding the opening day and Saturday, upon which days respectively 47,835 and 57,703 were admitted, the attendance on ordinary days has averaged 32,000 a day.

PIG IRON.—The price of pig iron has again dropped. On Saturday last it reached 37s. 11½d., and on Monday morning touched even 37s. 10½d. The number of furnaces in blast is eighty-seven, as compared with eighty-one last year. Stocks in Connal's stores are still increasing, and shipments are languid; although steel is in request, and the local demand for some classes of iron steady, there is little inclination to buy forward, notwithstanding that the price is now probably below the average cost of production. The shipments last week were 7616 tons, against 8182 tons last week, and against 9156 tons for the corresponding week last year.

(From our own Correspondents.)

LIVERPOOL, 16TH MAY, 1888.

OPENING OF A NEW DOCK FOR LIVERPOOL.—The last of the series of three docks, forming the South Docks Extension Scheme, was opened last Thursday by the entry of one of Messrs. Brocklebank's large sailing vessels, without any ceremony or formality. The "New Toxteth Dock" has a water area of 11¼ acres and a quay space of 1100 square yards, and is therefore one of the largest of the present system. Extensive warehouses and sheds, fitted with all modern appliances for loading and discharging vessels, are in course of construction. The total length of quay space in the whole system of the Liverpool Docks has now been increased to about 22¾ miles.

FIRE EXTINGUISHER FOR STEAMERS' HOLDS.—An interesting and successful experiment was made last Monday with an apparatus designed by Messrs. Coates & Carver, of Manchester, for extinguishing fires in ships' holds, in the presence of a number of the Dock Board officials and the superintendent engineers of the various shipping firms. The principle of the invention is to force the products of combustion of the main or donkey boiler into the burning mass; the carbonic acid gas and carbonic oxide being very effective extinguishers. A large fire of coal and timber, soaked in creosote, was made in the interior of a large pontoon, the manholes being removed to create a current of air. In a very short time after the gases from the combustion chamber of a small donkey boiler had been applied, the fire was extinguished; and to remove the poisonous vapours within the pontoon, the same apparatus forced in sufficient fresh air to enable a boy to enter safely within a few minutes.

SHEFFIELD, 16TH MAY, 1888.

THE HEAVY TRADES.—The condition of local trade continues to be fairly satisfactory. The quotations of both pig iron and Bessemer steel are in favour of the buyer, as the prices are very low. Finished iron is selling 1s. 6d. to 2s. 6d. per ton cheaper. Bars are going at £4. 10s. and £4. 12s. 6d., although the best makes bring from £5 to £5. 10s. Bessemer billets are quoted at yielding prices, and the competition in the steel rail trade is now so keen that sections can be obtained at what seems a remarkably low figure. Nearly all the orders on hand for railway material are now for distant lines, and the output on foreign account is very extensive. Tyres, axles, and springs are in demand for both home and colonial use. The waggon builders are also well engaged, coal trucks and low sided goods vehicles being in better request. At the rolling mills, work has been plentiful during the past six months. There is a good deal of activity in the engineering shops, several extensive orders having recently been received for heavy machinery, both for home customers and for shipment. Sheffield makers are turning their attention particularly to the improvement of labour saving machinery, and are steadily developing their trade. There is also a great deal of experimenting going on with a view to improved steel manufacture. It is felt by some makers that there are still greater possibilities in the steel trade than have yet been grasped, and accordingly experienced workmen are taken into their counsels, as well as analysts; the result may be a still cheaper steel, that will

Digitized by Google

supersede iron for more purposes than ever. It is satisfactory to note that there is a growing inquiry for heavy English goods abroad, and Japan, India, and the Argentine Republic are dealing extensively with Sheffield houses; but the United States are depending more and more on their own manufacturing resources.

COAL.—Manufacturing sorts are in excellent demand; but coal for household purposes only finds a quiet market, though it is selling 1s. per ton cheaper. The output for shipment has lately been decreasing, and at some of the South Yorkshire pits the miners have been working short weeks. It is believed that the negotiations between the Midland and the Hull and Barnsley Companies, as to the taking over of the line through the Wolds to Hull, are now at an end. But there is some talk about the probability of the coal owners finding a cheaper mode of transit to the coast by using the inland water ways.

LEEDS, 16TH MAY, 1888.

IRON AND STEEL.—The finished iron trade of Leeds has decidedly improved during the past fortnight, and orders are coming in plentifully. Some makers, too, are obtaining rather higher prices. Locomotive builders are busy. Messrs. Kitson have good orders on hand, and there is great activity at their shops. The demand for locomotive, tram, and stationary engines is improving; and in the engineering trade employment is easier to obtain. There is a more favourable call for agricultural machinery. For engineers' tools the market is satisfactory, and there is a renewed demand for cut nails.

TEXTILES.—There is scarcely a stagnant branch in textiles. Orders are numerous even at stiffening prices in all the branches of the textile trade, and goods for summer wear are urgently called for. Worsteds and serges are selling well for next winter's use, and manufacturers of attractive cloths, either for present or winter wear, are doing well. Trade is very bad, however, at some of the old mills that still employ the old style of machinery; and the makers who are doing the trade are those who have adopted the latest improvements in plant, and introduced new patterns.

THE STRIKE.—The comments about the "sweating" system have led to action on the part of the Jewish tailors. About seven thousand of them have struck at the busiest part of the season, and several of the large clothiers are consequently suffering.

NORTH STAFFORDSHIRE, 16TH MAY, 1888.

THE IRON TRADE.—There is no improvement to report in the various branches of the iron industry, either with regard to prices or demand; and the immediate outlook affords no prospect of improvement. Last year there was a decrease in the production of puddled bars in this district, to the extent of over 11,500 tons, as compared with 1886. At the present time, out of the 390 puddling furnaces in existence, there are 100 inoperative; of the remaining 290, the annual average production per furnace is about 540 tons. In the case of pig iron there was an increase of production in 1887 of nearly 43,000 tons, as compared with the preceding year, which was due to the blowing in of additional furnaces in the latter half of the year. At the present time out of 39 furnaces in existence there are 21 in blast, the annual average production per furnace being about 266 tons.

THE POTTERY TRADE.—There is a decidedly better feeling amongst manufacturers, and a general concurrence of opinion that there is some little improvement in demand. Up to the present time prices have not been affected, but the outlook is regarded from a more favourable point of view. America and the Colonies take the largest proportion of this district's productions, more particularly of cheap lines. The home demand also shows some tendency to expand. Manufacturing fuel is in fair request, prices ranging from 6s. 6d. to 8s. 6d. at the pit, according to quality.

SOUTH WALES, 16TH MAY, 1888.

NEW STATION.—The secretary of the Great Western Railway Company has intimated that plans are being prepared for the construction of a railway station at Roath.

THE CYFARTHFA FURNACES.—The third of the blast furnaces erected at Cyfarthfa, some years ago, and which has remained idle for want of sufficient engine power, has just been put into blast, and is working satisfactorily. Messrs. Davy Brothers, of Sheffield, have supplied the new blowing engine, which has a 44in. steam cylinder and 96in. blast cylinder, with 5ft. stroke.

TIN PLATES.—The recent fluctuations in the price of tin have been of such a character as to completely paralyse manufacturing operations, in so far at least as the booking of orders is concerned. Buyers and sellers remain quite apart; and as the meaning and real cause of the great fall in the price of the metal has yet to be generally understood, uncertainty as to the future is still the prevalent feeling. Makers cannot err, however, in covering their probable requirements for some time to come at the present price.

COLLIERY EXPLOSION.—A few minutes after midnight last Sunday, a terrible explosion occurred at the Aber Colliery, Ogmore Valley, by which five men lost their lives. Mr. Robson, the chief inspector of mines in the district, states that in all probability the explosion was caused by gas ignited by a naked light. As this is not a fire damp colliery, the sad event affords another example of the danger run by the neglect of precautions which long immunity from accident is apt to induce.

BARROW-IN-FURNESS, 16TH MAY, 1888.

WOOD PULP WORKS.—The arrangements which have been in progress for some time for the establishment of wood pulp works at Barrow have at length been completed, and immediately after Whitsuntide the prospectus of a new company will be issued. The chief promoters are Mr. Partington, of Manchester and Glossop, paper maker, who holds the patent right, and Mr. T. Briggs, of Manchester and Barrow, jute manufacturer. By the agreements entered into, Mr. Partington sells his patent right for £43,000, and takes shares to the value of £40,000 in the new company. Only about £50,000 out of a capital of £120,000 will be offered for general subscription, and Mr. Partington guarantees 6 per cent. for ten years on these shares. A suitable site for large works has been secured at the east end of the docks at Barrow. The timber used will be imported, and thus the docks and the railway will benefit by the traffic, while at the same time Barrow will secure another new and important industry.

IRON AND STEEL.—There is nothing new to note in the iron and steel trades except the fact that the demand occupies even less dimensions than of late. There is less inquiry for both pig iron and for steel. Pig iron remains exceptionally dull, and there are no indications of any improvement. On the contrary, it is evident that the large consumption on the part of steel makers is almost alone responsible for the great bulk of the trade now being done. Prices are unchanged at 42s. 6d. per ton net f.o.b. for mixed parcels of Nos. 1, 2, and 3 Bessemer, and 41s. 6d. for No. 3 forge and foundry iron. As stocks have accumulated to a large extent at the works and in the store yards, it is contemplated, in view of the lowering tendency of prices, to restrict the output of the district by blowing out a few furnaces. It is evident that stocks have been allowed to get too large; but that is not entirely the fault of this district, but of all other hematite producing neighbourhoods. Business has been done in hematite warrants at fully 1s. below the prices quoted by makers. In the steel trade there is still great activity, and in all departments makers are very fully employed. Rails still represent the chief feature of the output; but it is also observable that considerable progress is being made in the development of the Siemens-Martin department. Rails are quoted at last week's rates—£3. 17s. 6d. for heavy sections, and £4. 2s. 6d. for light sections net f.o.b. Ship plates are in good demand, and have been largely ordered forward. Prices are steady at £6. 15s., and at £6. 2s. for angles.

MIDDLESBROUGH, 16TH MAY, 1888.

PIG IRON.—There was a very small attendance on 'Change yesterday, and little or no business was done. Prices are much the same as last week, although there are buyers at 1½d. less. Still, the quotation for No. 3 G.M.B. is 31s. 3d. per ton for delivery over the next two months. Warrants are 30s. 11d. per ton cash for Connal's No. 3 G.M.B., and for Connal's hematite 42s. 6d. The stock in Connal's store is decreasing, and amounted on Monday night to 301,391 tons. Makers hold out for more than the quoted price, some insisting upon 31s. 6d., and others 32s.; but no sales are reported.

SHIPMENTS OF PIG IRON.—The shipments of pig iron from the port of Middlesbrough this month promise to exceed even those of last month, which were remarkably good. Up to the 14th, no less than 54,046 tons have been shipped, against 43,218 tons to the same date last month. It is considered, however, that this cannot continue much longer. Scotland is taking more than at the same time of last year, and Germany and Holland have nearly doubled last year's take. Other foreign countries have taken about a third more.

STEEL AND MANUFACTURED IRON.—These are much the same as last week except in manufactured iron, where from 2s. 6d. to 5s. reduction has been made to secure orders. The mills are working full time on old orders, but new ones are few and far between. There is no pressure now from the ship yards, which are quieter than they have been for some time past. At the Darlington Steel and Iron Works there is a lock out, caused at first by the manager objecting to the men joining the Steel Workers' Association, but in the end by a difference as to agreement in the rate of wages.

SUNDERLAND, 16TH MAY, 1888.

SHIPBUILDING.—Shipbuilders continue to be actively employed, and orders recently received exceed the number of vessels launched. It is anticipated that there will be an influx of orders as the time draws near for the enforcement of the increased scantlings for steel steamers which have been agreed upon by the Committee of Lloyd's Register.

SHIPPING TRADE.—The Black Sea and Baltic homeward freights are now of a remunerative character, and a great improvement has taken place in the Bilbao trade. Outward American rates are also firm, but homeward rates are still very low. During the last week, the trade of the port was fairly satisfactory—78,280 tons of coal were shipped, as against 76,173 tons in the previous week, an increase of 2107 tons; 35,022 tons were exported, and 43,258 tons sent coastwise. Other shipments comprised 853 tons of coke, 560 tons of patent fuel, 33 tons of cement, and a general cargo. Foreign imports included 160 tons of scrap iron, 1569 pieces of teak timber, 100 pieces of teak planks, 400 packages of hay, 750 tons of iron ore, moss litter, pit props, sleepers, poles, matches, and paper. Coastwise there were several cargoes received, including iron rails, scrap iron, wheat, chalk, timber, &c.

NEWCASTLE, 16TH MAY, 1888.

IRON.—The circumstance that pig iron shipments from Middlesbrough have been unusually heavy during the first half of the month, tends to strengthen the view that a better demand for the finished commodity is likely to arise ere long. The use of iron for the interior fittings of steamers in cases where the hulls are of steel is gradually extending; and though a structural change of this kind must ultimately have an adverse effect upon the steel trade, it will of course give a proportionate and much needed stimulus to the finished iron trade. The rolling mills at Winlaton, Gateshead, and Jarrow continue to work very steadily, and the output of product is quite double of what it was a year ago. Messrs. Raine & Co., of the first named place, are under a contract to supply a large quantity of heavy chain iron to a firm of Sunderland chain manufacturers during the present year. As announced in *Industries* a few weeks ago, the blast furnaces at Walker, which have stood idle for some years, are being rapidly prepared for re-starting, and will probably be in operation by the end of the present month.

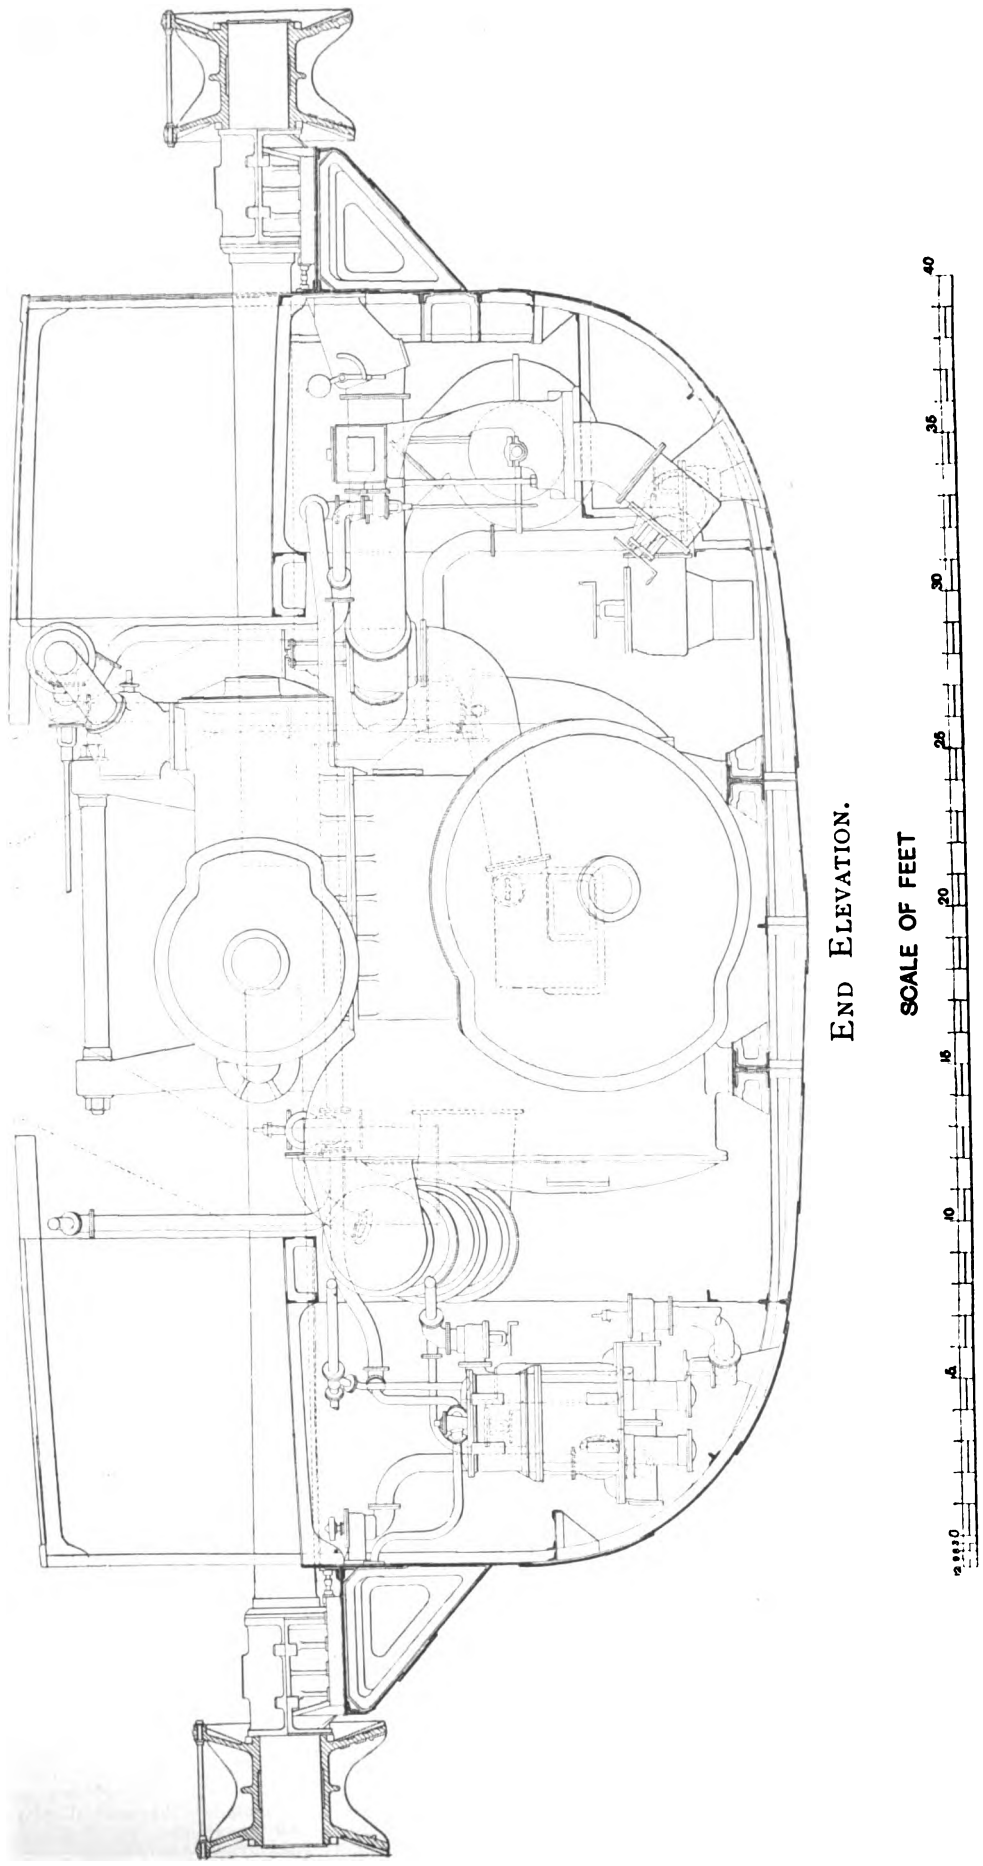
STEEL.—The second of the Siemens-Martin furnaces erected by Messrs. Hawks, Crawshay, & Sons, at their Park Lane works, will be put in operation this week, and, as a consequence, the staff of hands employed will be largely increased. The orders in the hands of the firm for steel plates and angles are very numerous; and it is, therefore, quite certain that unless some brief stoppages for repairs should become necessary, the productive resources of the establishment will be fully utilised for some months to come. At Jarrow and Consett the steel works are exceedingly busy, and the output of plates, angles, &c., is unprecedentedly large. The demand for steel sheets is still satisfactory; but prices show a slightly weakening tendency, a change which is more particularly noticeable in galvanised sheets. Messrs. Cail & Davies, of the Redheugh Steel Works, have lately shipped some large parcels of steel sheets to a Continental destination.

CHAIN AND ANCHOR WORKS.—The demand for anchors, and more especially for those types which are designed to fit into the hawse pipes, is very active; and in some instances the manufacturers are unable to keep pace with customers' requirements. A wages dispute still causes Messrs. Abbot's chain department to be inoperative, a fact the more to be regretted as there is now a good demand for cable chain; and many orders which might have been obtained for these works are being sent elsewhere.

THE "BECK" GAS ENGINE.—Messrs. Black, Hawthorn, and Co., the manufacturers of the "Beck" gas engine, have put down special plant for the production of that specialty, and have now a large number of orders in course of execution. A 16 h.p. engine has lately been supplied to Messrs. Palmer & Co., Jarrow, to drive the machinery in their pattern making department, and one of similar type was delivered to the Wearmouth Coal Company to drive the machines in their fitting shop. The latter has been at work some time, and is found to be a most effective and economical motor.

BELFAST, 16TH MAY, 1888.

RAILWAYS.—The work on the new loop line in Dublin, from Westland Row to George's Quay, is now making rapid progress, all the houses and other property having been cleared away. The contract for the masonry work in connection with the line has been given to Mr. Meade, of Great Brunswick-street, who is bound to have his work finished by November 1st. A meeting was held on the 26th ult., in Cushendall, county Antrim, to promote a tramway scheme between Retreat Station, on the Ballymena and Redbay Railway, and the town of Cushendall, along the new road to Ballymena, now being constructed; the tramway would be about five miles in length, over a hilly country, and the total cost, including plant, would be about £20,000.



WOOLLEN TRADE.—A large amount of business has been done during the past fortnight in summer goods, and the trade is increasing, as manufacturers are striking out new lines and introducing new patterns of goods. Messrs. Ross, of Bloomfield, Belfast, who have only lately taken up this industry, are at present erecting new wool spinning machinery, and are about to increase the number of their power looms, to keep pace with their rapidly increasing trade. The Irish Woollen Manufacturing and Export Company held its meeting in Dublin, when a dividend of 7 per cent., free of income tax, was declared on the paid up capital. The chairman in his speech pointed out that their goods were to be found now in all the principal towns of the United States and Canada, and also that Berlin and other Continental centres were gradually adopting their goods and writing for samples. They had also made arrangements to send displays to the Irish Exhibition at Olympia and to the Melbourne Exhibition.

LINEN TRADE.—The trade in yarns still continues rather dull, without any sign of speculation, and prices remain steady. Tows also continue quiet, with prices unchanged. Cloths are in good demand, and prices are fully maintained. Brown goods sell freely, and manufacturers are asking slightly higher prices. Finished linens remain unaltered at late prices. Manufacturers of collars, cuffs, &c., are very fully stocked with orders, and in some cases are taxed beyond their powers of production.

COMPOUND PADDLE ENGINES OF THE S.S. "QUEEN VICTORIA."

CONSTRUCTED BY THE FAIRFIELD SHIPBUILDING AND ENGINEERING COMPANY, LIMITED, GLASGOW.

END ELEVATION.

SCALE OF FEET

PADDLE ENGINES OF THE MANX LINE STEAMER "QUEEN VICTORIA."

As promised in our last week's issue, we give herewith an end view of the engines of this vessel, and on our two-page supplement this week we give a general plan of the engines and boilers. As will be seen, the engines are of compound diagonal direct acting type. The high pressure cylinder, which is nearly horizontal, is 61in. in diameter, and the low pressure cylinder, which is placed diagonally beneath the high pressure, is 112in. in diameter. The stroke of each is 6½ft. Both cylinders are fitted with slide valves, which are worked by the usual double eccentrics and link motion, and reversed by one of Messrs. Brown Brothers' steam and hydraulic reversing engines. The water for condensing the steam is circulated through the surface condenser by a centrifugal pump driven by a separate engine. The paddle wheels have feathering floats, and, together with the paddle shafts, paddle arms, feathering rods, and all other parts of the machinery, wherever practicable, are made of steel. The boilers are four in number, and are double ended, each 15ft. in diameter, and 19ft. 6in. long. There are six of Fox's patent corrugated furnaces in each boiler. The working pressure is 110lb. per square inch. Forced draught on Laing's closed ash pit system is employed, the fans and engines being of special design. The main feed pumps are separate from the main engines, and are worked by independent engines on the Worthington principle. The main engines indicate upwards of 7000 h.p. It will be remembered that during last season the sister ships made many very rapid runs. On her trial trip the "Prince of Wales" averaged on a six hours' run the extremely high speed for a paddle steamer of twenty-six miles per hour.

COAL, IRON, AND COGNATE INDUSTRIES.

THE Board of Trade returns for the month of April must, on the whole, be considered satisfactory, and are a distinct improvement on those which we had before us to examine last month. The total value of the imports during April was £32,098,693, being an increase of about 3 per cent. over those for the corresponding month in 1887. The total declared value of the exports was £17,735,474, as against £16,411,662 in April last year, being an increase of about 7·4 per cent. The total quantity of iron and steel exported during the month was 327,215 tons, valued at £2,104,163, being an increase of 5937 tons and £186,910 as compared with April, 1887. The exports of iron and steel rails amounted to 47,600 tons, being an increase of 2731 tons as compared with the same month of last year, an improved demand from the Argentine Republic, Japan, and Egypt having more than counterbalanced a falling off in the shipments to Italy and Australasia. We append our usual tabular statement with reference to the trades under review :—

	Month of April.		Four months.	
	1888.	1887.	1888.	1887.
	£	£	£	£
Pig and puddled ...	211,538	257,981	605,155	807,712
Bar, angle, &c.	131,791	88,305	547,176	413,335
Railroad.....	356,054	282,341	1,552,728	1,065,157
Cast and wrought.	371,571	302,284	1,556,524	1,342,065
Hoops, sheets, &c...	326,056	297,206	1,288,988	989,675
Steel, unwrought...	91,875	177,599	429,876	729,420
Tin plates	466,302	384,853	1,779,124	1,432,456
Unwrought copper.	154,261	95,626	749,177	329,190
Coals	787,592	781,263	3,065,095	2,997,210

In each item of the above table the returns must be regarded with satisfaction, excepting those two which relate to the crude metals—iron and steel—in which there is a startling diminution. We have frequently called attention to the necessity for British iron and steel makers to develop markets other than the American Union for the consumption of their products. Having regard to the fact that in 1887 the make of pig iron in the United States was little more than 250,000 tons less than that of the United Kingdom, and the production of Bessemer steel ingots was greater by nearly 900,000 tons, it is apparent that not only will that country be capable of meeting all its home requirements, but that there will some day be a surplus manufacture to compete with us.

With regard to the home market since our last review of these industries, a retrogressive tendency has been in operation. From all sides we hear complaints of prices, which have now reached a lower level than obtained last year, and which are in many instances below cost of production. To low prices is now added a slacker demand, and the outlook for the immediate future is gloomy indeed. Scotch warrants are under 38s., which is, probably, the lowest price on record, and in spite of a considerable reduction in stocks, amounting to above 27,000 tons since the beginning of the year. In the Cleveland district prices in that centre remain low in sympathy with Scotch pig iron. In the Midlands, Northamptonshire, and Lincolnshire, pigs are now quoted 5s. per ton below the ruling rates at the January quarterly meetings; and in all cases the various branches of finished iron participate in the fall, which is still going on.

Advertisements intended for insertion in the current week's issue must reach the Manchester Offices not later than first mail delivery on Thursday morning. Scale of charges for displayed advertisements on cover and inside pages will be forwarded on application. Orders for single advertisements must be accompanied by payment in order to insure insertion, the charge for which is 2s. 6d. for the first four lines or under, and 8d. for each additional line; one inch and over at 7s. per inch; the line averages eight words. While all practical regularity in the insertion of serial advertisements will be observed, it can only be absolutely guaranteed in the case of those ordered to appear weekly.

All accounts are payable to the Publisher, JAMES F. BUTTERWORTH, *70, Market-Street, Manchester. Cheques should be crossed Manchester and Liverpool District Bank, King-street Branch, Manchester. Post Office Orders to be made payable at Manchester.*

With a Double-page Supplement, showing the
COMPOUND PADDLE ENGINES AND BOILERS OF THE S.S. "QUEEN VICTORIA."

To Correspondents.

All communications intended for insertion in this Journal, or relating to Editorial matters, should be addressed to "THE EDITORIAL DEPARTMENT," either at the Manchester or the London Offices, and must, in all cases, be accompanied by the name and address of the writer. No notice will be taken of anonymous letters.

We cannot undertake to return manuscripts or drawings, and must request correspondents to keep copies.

Industries, VOLS. I., II., & III.

From July, 1886, to December, 1887.

A few Copies, handsomely bound in half calf, gilt lettered, may now be had at the Head Office, 70, Market-street, Manchester, Price 20s. each.

Industries:

FRIDAY, 18TH MAY, 1888.

OUR INLAND WATER-WAYS.

THERE never was a time, perhaps, when the cost of transport attained so high a degree of importance as at the present. The keen competition under which trade has now to be carried on has rendered it necessary to keep down all costs, those of distribution as well as those of production, to the lowest possible point; and this necessity has grown more urgent as our difficulties have increased, in consequence of the depression which for a long time past has weighed upon all our staple industries. Manufacturers have come to regard our railway systems, with their high tariffs and wide reaching monopolies, as a serious obstruction to trade, and have in consequence sought to obtain some amelioration of the conditions imposed by those powerful organisations, the railway companies. Hitherto their efforts have been attended with little or no success; and outside the circle of traders interested, their difficulties have attracted no serious attention. But the migration of manufacturing works to the sea coast, which is taking place in consequence of the failure of their owners to obtain relief from the railway companies, has alarmed the whole industrial community, and the question of inland carriage may be truly said to have become a national one. Manifestly our position as an industrial and commercial people is closely bound up with it. Either we must find means of cheaper transport, or the inland country will soon be denuded of all its great manufacturing works. Unfortunately, when this movement has once set in, it does not always end at the sea coast. Emigration has happened in several instances, and we have witnessed the transfer of British capital and British energy to foreign lands. No wonder, then, that the question of inland navigation has come prominently to the front. In this seems to lie our only means of salvation. Such at least is a common opinion, and this view of the matter was strongly represented last week at the Conference held in London under the auspices of the Society of Arts. To one who has not given much thought to the subject, it may appear strange that our water ways should have been so utterly neglected, if they are indeed capable of affording us the means of cheaper carriage than the railways. But the practice of our rivals on the Continent leaves us no room for doubt in this matter. They have put the question to the test of experience, and the result has proved satisfactory in every particular. The Commission of inquiry appointed in 1878 by the French Chamber of Deputies reported that "coal cannot be carried on railways, even for long distances, at a less cost than from 0·54d. to 0·62d. per ton per mile, while on the canal the cost of transport does not exceed 0·22d. per ton." On this point there was but one opinion among the members of the Conference; and as they were all men of extensive practical knowledge, it may be accepted that canal transport as effected in the present day compares very favourably in cost with that of the railway.

Our Continental neighbours and rivals in trade have been more quick to perceive and more ready to avail themselves of the advantages afforded by water carriage than we. They have gradually developed their system of canals, pushing out their extensions under more favourable conditions than those in which the earlier water ways were established. That is to say, the newly constructed or newly projected canals are designed to float large barges or other vessels; they are uniform in the gauge and system of locks; the latter are reduced in number by the adoption, in some places, of hydraulic lifts; and the haulage is effected by steam power. The Germans are especially active in developing their system of inland water ways, and in the most recent projects we see the highest fulfilment of economical conditions yet attained. This progress in canal engineering tends to reduce the cost of transport still further. Hence it is evident that if foreign competition has cost us much in the past, it will become ruinous in the future if we continue on present lines. It was freely admitted at the Conference that we had lost heavily of late in our foreign trade, and the cause was declared to lie chiefly in the cheap water carriage existing abroad. Abundant evidence was adduced in support of this assertion. Some typical examples may be quoted. The iron masters of Liège and Seraing in Belgium get their imported ores brought from Antwerp by water, a distance of over one hundred miles, for 2s. a ton, and their manufactured iron and steel conveyed to Antwerp, for export, at the same low cost. The rate paid on English iron from South Staffordshire to London by railway is 14s. a ton. The corresponding rate under the Belgian canal tariff would be 3s. a ton. Iron is delivered in London from works in the middle of Belgium at a cost of only 5s. a ton of carriage, including canal dues, post dues, sea freight, and insurance. Quite recently, in the case of a large contract for steel rails, the difference as between Sheffield and Belgium was 2s. 11d. per ton. Had the former possessed adequate water communication with the Humber, Sheffield would have gained the contract; but as it was, the extra 2s. 11d. took the whole business to Belgium. Pottery is imported into England from Germany, Belgium, France, and Sweden at a cost of about 7s. a ton for freight, thanks to the inland water carriage. The railway rate to London from the Staffordshire Potteries is 30s. a ton. Maastricht can send ware to Burmah for 10s. a crate less than we can. Plaster and cement is largely imported from Paris and other parts of the Continent, because the land carriage renders it unprofitable to work and manufacture these materials in the Midland Counties. Examples of this sort might be multiplied without number. It is satisfactory to learn that while the members of the Conference were agreed as to the cause of this loss of trade, there was the same unanimity in declaring the remedy to be in the adoption of water carriage.

Geographical conditions and the maritime character of our commerce require, not a network of inland canals, similar to our railway system, but a few main water ways, by which our principal centres of industry would be easily accessible to sea-going vessels. The Manchester Ship Canal will constitute the first of these, and if the success anticipated be achieved, there will be but little difficulty in promoting other undertakings of a similar character. Birmingham certainly will not be long without its ship canal. Ways like these, particularly the latter, will need each its system of feeders. These secondary canals must be designed to fulfil the conditions of cheap transport; that is, they must not be the mere ditches which now exist under the name of canals, but they must be of large and uniform section; regular and uniform, too, in their system of locks, and

Digitized by Google

these should be reduced to the smallest practicable number by the adoption of hydraulic lifts. The canals of the future must exhibit in their engineering features the same progress which marks the railway. On this head there was no difference of opinion at the Conference. The same unanimity prevailed relatively to the urgency of the need. Divergence arose only when the means of accomplishing the work were proposed. According to some, State aid is indispensable; and, judging from the resolution passed by a large majority, this view was entertained by the greater number of those present in the Hall of the Society of Arts on Friday last. The resolution, as finally agreed to after long discussion, runs thus: "That the Legislature should seriously consider the necessity of encouraging and assisting the improvement and extension of the canal system by State acquisition or otherwise; and that, meanwhile, this Conference urges the House of Commons to amend the Railway Traffic Bill by authorising local authorities to constitute public trusts for the development of the existing system of canals." This is the outcome of the Conference. It remains to be seen to what practical result it will lead. But the representatives of our great national industries are in no mood to brook delay; and whether or not the aid of the State be granted, they will push on their scheme to completion. This, at least, was to be gathered from the tone of the Conference. Private enterprise can effect much, and, as Mr. Daniel Adamson remarked in the course of the discussion, money will be forthcoming to any amount if the undertaking can be shown to be profitable. Possibly it would be to the advantage of British industry that a work of this character should be left to private enterprise.

THE PRINCIPLE OF ANTAGONISM.

If one cared to run to extreme such ideas as those of Buckle on the influence of climate upon character and opinion, or of Jevons on the influence of sun spots upon commerce, one might indulge in speculation as to the periodicity of certain scientific generalisations. Scientific thinkers, especially those who live apart from the conflict of opinion in the great world, and who work out special problems in isolated state, not infrequently astonish themselves and everybody else by discovering something that has been a commonplace for ages. They are deceived into believing that they have found something new, merely because they have arrived at it by a route which was not open to their scientific ancestors; and the public too readily assume that a new name covers a new principle. Thus there are scientific generalisations which appear with almost undeviating regularity at least twice in every century. That they are re-discovered and re-stated so often, affords a certain presumption of the tentativeness of all such generalisations, and shows the advisability of examining the more carefully the interpretation they give of natural phenomena, the more consonant with common experience these generalisations may at first sight appear to be. Among generalisations whose periodicity it would be interesting to investigate, is that currently known as the "struggle for existence." It would be tedious to recite the list of appearances of this scientific comet. From Heraclitus at Ephesus to Sir William Grove at the Royal Institution is a long stride in point of time, and during its progress the idea of the "struggle for existence" has come and come again in apparently spasmodic, but probably really in regular, periods. Now the influence of Plato, and now that of Hegel, blotted it out of sight, and now the persistence of Malthus and of Darwin thrusts it again into view. Of late it has been noisily pointed out, not so much by the younger groups of scientific thinkers as by men of the older school, who, largely unconsciously, turning their minds upon the ideas of their youth, find among them this generalisation which affects them in their age with the force of a new inspiration. For, however speciously disguised in its new dress, the "principle of antagonism" of Sir William Grove in 1888 is simply the "struggle for existence" of Malthus in 1798 and of Darwin in 1859. While one may admit the advance in science made by the generalisation in its first, and even in its second form, it is open to question whether the mere repetition of it without qualification or addition is to be regarded as of the nature of growth. Sir William Grove prefaces his statement of the "principle of antagonism" by references to ancient metaphysics and mythology, and follows very much the same line as did Professor Huxley in a recent paper. When men of science turn to metaphysics, we may well suppose that they have at least for the moment abandoned serious thinking, and have made up their minds to have some relaxation. Such an Easter holiday amusement is Sir W. Grove's "principle of antagonism." Even if this were the place to discuss the metaphysical problem of the "identity of contradictories," which it is not, we might very well appeal to the precedent of Plato's treatment of Heraclitus and his school, and decline to regard as "serious philosophers" the latter-day Heracliteans who, seizing upon a single and very manifest truism, have made it do duty as a general explanation of the phenomena of nature. Yet such conceptions of the expression "struggle for existence," when applied to industrial life by biologists like Professor Huxley and physicists like Sir William Grove, demand examination and criticism from a practical as distinguished from a metaphysical point of view. In our issue of the 24th February, we offered some criticism of the conclusions of Professor Huxley in his recent article in the *Nineteenth Century*, and now the address by Sir William Grove, at the Royal Institution, seems to demand examination from the same standpoint. It is worth our while then to ask whether Sir William Grove's application of "the principle of antagonism" to the phenomena of commerce affords an adequate explanation of those phenomena. "The principle of antagonism," as stated by Sir William Grove, is that which dominates the play of forces. In his view the universe is pervaded by forces striving against each other; if this strife were to cease, the whole scheme of things would collapse. Antagonism is thus an indispensable condition of existence. This antagonism, pervading as it does the whole universe, "is associated with unorganised matter, with organised matter, and with sentient beings." From this general statement of the principle, Sir William comes down to particulars; he finds individual atom fighting individual atom, white corpuscles fighting *bacteria*, and communities of men fighting communities of men. More, he points out how the combative elements in daily life, games, commercial competition, the war of advertising and the like, are due to this principle of antagonism. All this is very interesting, though it has been said before; but it will be observed that there are involved in these statements two principles of antagonism and not one. There is the larger principle of antagonism, which may be regarded as the playing against each other of the great physical and social forces. In this sense the principle as applied to commerce would include both competition and its opposite monopoly, and as applied to physics would comprise the play of, for example, centrifugal and centripetal forces. In the smaller sense the principle would regard the strife of individual atoms engaged in the competitive strife which in the field of commerce is one side of the larger antagonism, and similarly with physical forces. It is obvious that while the principle is universal and valid in the large sense, it is neither universal nor valid in the small sense. There is always antagonism between the great forces in the universe, but there is not always strife between each individual atom and its neighbour.

That the distinction here drawn between the principle of antagonism in the larger and valid sense, and the principle in the smaller and invalid sense, is an extremely important one, will appear if we note the confusion which exists in the minds of scientific speculators who ignore the distinction. Professor Huxley for example is found defining the history of civilisation as the record of the attempts which the human race has made to escape from a state of strife. In the small sense this is hardly true, in the large sense it is not true at all. It cannot be true if the principle of antagonism is, as Sir William Grove says it is, a necessity of existence. It is futile to attempt to escape from the necessities of existence; and one cannot say that civilisation has been altogether futile.

The confusion between the principle in its larger sense and the principle in its smaller sense really vitiates the bulk of Sir William Grove's conclusions. An illustration will make this comparatively clear. He undertakes to show, as reported, that there are *evils* in the excessive exercise of antagonism. These very expressions suggest a looseness in method. A universal law of nature can hardly be spoken of as being in excess. Antagonism exists, let us say, between two forces, one a centrifugal force, and the other a centripetal force. Should the centrifugal force prevail, and always prevail, should this be regarded as excessive exercise of antagonism? Might it not as justly be called a deficiency of antagonism, and, more accurately, might it not be regarded as showing simply the preponderance of one force over another, the question of excess or otherwise of antagonism not entering into the question in the least? This is not a mere verbal quibble, for the view presented by Sir William Grove was in effect the rough and ready one, that antagonism is carried to excess when the force we want to win does not win.

The fundamental error both of Professor Huxley and of Sir William Grove appears to lie in their regarding the principle of antagonism as an adequate explanation of phenomena much too complex for exposition by so easy and ancient a generalisation. There are other principles at work besides the "principle of antagonism." Howsoever one may admit its pervasiveness even, one may well decline to admit the existence of unremitted strife. There is such a phenomenon as a couple, and Sir William Grove himself has shown in earlier days how there is correlation and continuity of forces. "The principle of antagonism," as a general principle even, is of purely negative value. Assuming an absolute antagonism, or perfect balance of forces, motion, and therefore life, would be impossible. As a theory of dynamics, then, the principle of antagonism is useless. As applied to the phenomena of society, and of industry and commerce, the "principle" does not seem to shed a single streak of fresh light. In social, as in physical phenomena, at one time centrifugal, and at another time centripetal, forces prevail. At one time the tendency is for society to break up into its elements, and at another to concentrate its energies, and as it were mobilise its members. At one time the direction of social progress is towards competition, at another towards its opposite monopoly. At one time it makes for the growth of individual effort, at another time for the growth of its opposite social effort; in all there is a play of forces, a "struggle for existence" of social forces, even an "antagonism" of social forces. But this broad view of antagonism is not that expressed by Sir William Grove, for he speaks of a possible excess of antagonism which shows that what he means is a strife of individual atoms, a strife which sometimes exists and sometimes does not exist, and which is modified and directed by other principles, as for example the love of offspring and the need of combining on occasion for common objects. In this narrow view the principle of antagonism is inadequate to account for the growth of such incidents of modern industrial life as joint stock enterprise, the growth of trade syndicates, of co-operation, of trade unions, or of any of the other numerous instances of the tendency at present abundantly manifest towards the development of associative effort; that is to say, a tendency towards a centripetal as opposed to a centrifugal movement in society. It is quite possible that the next generation may witness a counter movement in the other direction; but however, in the larger sense, social movements are governed by the "principle of antagonism," the evidence is against the conclusion that they are always governed by the principle in the smaller sense.

Letters to the Editor.

THE ELECTRIC LIGHT IN THE SUEZ CANAL.

To the Editor of "Industries."

Sir,—I observed, in the last issue of your valuable paper, a statement made on the authority of Consul Burrell, of Port Said, which is not absolutely correct. This is to the effect that the fastest passage of an ordinary steamer with the electric light was 15 hours and 5 minutes. On January 10th, 1887, I went through the Canal with the Peninsular and Oriental steamer "Rohilla," from Suez to Port Said; passing the Canal Office at Suez at 8-45 a.m.; lighting up the projector at 6 p.m., when the ship was at El Ferdane, and arriving at the moorings at Port Said at 10-55 p.m., exactly 14 hours and 10 minutes; and up till the time I left the Suez Canal (in May, 1887), and also from reports in various papers respecting quick passages, this ship certainly made the fastest on record, with the exception of the "Namouna," quoted by you.

I may mention a few other quick passages of the same company's ships by the electric light: June 18th, 1886, s.s. "Ravenna," 16½ hours' passage, 4 hours' light; November 15th, 1886, s.s. "Ganges," 16½ hours' passage, 10½ hours' light; Nov. 18th, 1886, s.s. "Assam," 16½ hours' passage, 11 hours' light; December 14th, 1886, s.s. "Verona," 15 hours' passage, 4 hours' light; January 27th, 1887, s.s. "Nizam," 15 hours' passage, 7½ hours' light.

The above examples are taken from a copy of my official log, where every detail of the passage by night was duly noted with regard to time, power of light, current used, &c.

Yours, &c.,

Frederick Walker.

4, Little Moorfields, E.C., 14th May, 1888.

THE REPORT OF THE RESEARCH COMMITTEE ON FRICTION.

To the Editor of "Industries."

Sir,—I agree with the remark of Mr. D. Adamson made at the meeting of the Institution of Mechanical Engineers, and reported in your last issue, that the third report of the Research Committee on Friction contained no practical advice. I notice the report publishes certain results as having been obtained on the friction apparatus with the use of "a mineral lubricating oil." As the mineral oils of commerce vary considerably, it would have been useful to know where the oil came from, whether it was pure, whether it had an admixture—as many mineral oils have—and what was its specific gravity, flashing point, &c. This information could easily have been given, and would show to some extent the basis on which the results were obtained. The speeds at which the apparatus was run were very low, viz., from fifty to one hundred and thirty revolutions per minute; and as the experiments are to be continued, it would be interesting if the committee could see their way to increase these speeds up to

Digitized by Google

4000 or 5000 revolutions per minute. I am aware that it is generally held that friction is independent of speed, and given perfect lubrication at both high and low speeds this may be so; but given the same pressure in both cases there is little doubt that much more heat is generated and has to be got rid of at high than at low speeds. In spindles where high speed is combined with considerable pressure, such as in wood planing machines, this is particularly noticeable. Some time since I experienced great difficulty in getting two vertical spindles—making some 7500 revolutions per minute—to run cool, and the heat engendered caused them to fire several times. I tried various kinds of oil and methods of lubrication without satisfactory results. The spindles were of mild steel, two inches in diameter, running in gun metal bearings, which were about two diameters in length. Both spindles and bearings soon became torn and abraded, and I replaced them by hard steel spindles and phosphor bronze bearings, increasing the length of the latter to three and a half diameters. Several of these machines have since been constructed, and no further trouble has arisen. This, I think, says something in favour of extended bearings and hard, close grained metal, both for high speed spindles and bearings.

The same oil is often made to do duty for all kinds of work, whereas its specific gravity, rate of application, &c., should be in ratio to the nature of the work to be performed, bearing in mind the pressure on and speed of the parts to which it is applied.

Yours, &c.,

London, 14th May, 1888. M.Inst.M.E.

THE BOILER EXPLOSIONS ACT, 1882.

To the Editor of "Industries."

Sir,—Possibly the Commissioners holding the first formal investigation under the above Act are not so much to blame as your correspondent "Economiser" would seem to imply, when he writes of their not having seen fit to fix the costs upon the culpable persons. The sentence in their report, "No application was made as to costs," is thrown in promiscuously under the heading "Cause of Explosion," as though they were determined to say something on this point, and would gladly have made somebody pay something if only they had been asked to do so. But if this be the real meaning of the Commissioners' remark, it shows very clearly the wilful negligence of the Board of Trade in carrying out an Act which was specially framed to give that department most exceptional powers. It is all very well for Mr. Thomas Gray to assert that this is purely an "Inquiry Act;" but when it was passed the promoters were especially proud of section 7, whereby it was anticipated that the pockets of those who allowed boilers to explode might be touched, even if they themselves could not be proceeded against by criminal prosecutions. This power of making somebody pay the cost of inquiries was undoubtedly one of the chief features of the Act. If Mr. Gray really knew that as the Act reads payment of costs and expenses could not be enforced, why has he never attempted to have the necessary verbal amendment made? If, on the other hand, he only thinks that "payment cannot with certainty be enforced," why has he not tried to obtain a decision on the point by applying for costs in the first formal investigation that has been held? It is much to be feared that "Economiser" supplies the true explanation, when he alludes to an "anxiety to injure boiler inspection as at present carried out, and to elicit evidence to its disparagement . . . . so as to produce a feeling that compulsory inspection is essential, and that it can only be carried out under the care of the Board of Trade." But even assuming that the Board has been actuated by such a desire, might they not fall back on the information that has been supplied to them as their justification. In the recently published Memoranda Mr. Gray calls attention "to certain facts and figures which have been furnished to the Board of Trade by Mr. Lavington Fletcher, chief engineer to the Manchester Steam Users' Association." Now, Mr. Fletcher's feeling against the joint stock insurance companies—who, by his account, only care to make big dividends and neglect inspection, but who, nevertheless, are much more trusted by owners for inspecting their boilers than is the Steam Users' Association—is a matter of notoriety, and that Mr. Gray has been thoroughly imbued with Mr. Fletcher's views on the subject is abundantly clear from his annual reports on the working of the Boiler Explosions Act.

In his earlier reports, one of the chief impressions produced upon Mr. Gray's mind by a consideration of the cases that had been investigated was, that inspection by insurance companies did not prevent explosions—the very thing that Mr. Fletcher had so persistently urged for years. After a time, however, Mr. Gray discovered that even inspection by the Steam Users' Association did not prevent explosions, and the annual allusion to the fallibility of insurance companies was dropped. Later on Mr. Gray—having perhaps gained further insight into the doings of the companies—is constrained to remark (*vide* the report for the year ending June, 1887) that the examinations made under the direction of the companies have in the main been conducted upon a satisfactory system.

Is it, then, too much to surmise that the knowledge of the workings of the insurance companies gained by the Board of Trade, during the six years that the Boiler Explosions Act has been in operation, may have had something to do with the withdrawal of the proposed Boiler Registry and Inspection Bill, and with the hint thrown out in Mr. Gray's Memoranda as to the desirability of inquiring into the way the companies conduct their business? If the Board of Trade is honestly desirous of reducing the number of boiler explosions as far as possible, let it take steps for ascertaining: (1) The number of boilers in use in the United Kingdom, and (2) the number of such boilers under systematic inspection, either by various companies or otherwise. When these have been got, it will be easy to find the annual rate of explosions among inspected and uninspected boilers, and it can then be decided whether it is necessary to legislate for some system of compulsory inspection. When considering the subject, it will be well to bear in mind the second conclusion arrived at by the Select Committee in 1871, which was to the effect that *a great number of explosions arise from causes independent of and apart from anything that could be prevented by periodical inspection.*

Yours, &c.,

Manchester, 16th May, 1888. Flues.

GLASGOW INTERNATIONAL EXHIBITION.

Mechanical Section—General Description.—The mechanical section in the Glasgow Exhibition compares very favourably with such sections in former exhibitions. In certain departments which one might have expected to see well represented, there is an unfortunate deficiency. Notably wanting altogether is the department of locomotive engineering, in which the Paris Exhibition of 1878 was so strong, and in which even the Edinburgh Exhibition of 1886 possessed one of its most attractive features. Deficient also, though not entirely destitute of representation, is the department of marine engineering. Only one full sized marine engine is shown, and that, though an extremely instructive exhibit, is not a large one. There are several models, one of them a working model, and a great number of photographs; but more might have been expected from the city where the most notable improvements upon the marine engine have been effected, and where so many thousands of horse power are annually turned out. The machinery exhibits may, for purposes of convenience, be divided into departments, and to each of these we purpose devoting special attention. Each article following the present one will be written by a specialist in the department referred to, and instead of offering our readers merely descriptive detail, we shall endeavour to treat each department in a manner as fairly critical as possible.

The machinery section, as we have stated, will demand our special attention; but before entering into particulars of some of the chief exhibits, we propose in the meantime to take our readers with us in a general survey of the section. As will be seen from the plan of the Exhibition and grounds which we gave in our issue of the 27th ult., the machinery court is situated at the west of the main building, to which it forms an annexe. It has a floor space of about 160,000 sq. ft., and is divided into nine bays running north and south, the central one of which is wider and higher than the others, and is traversed by a 20-ton overhead crane, made by George Russell & Co., of Motherwell. It has a span of 41ft. 5¾in., and travels on longitudinal girders the whole length of the building, and is driven by a vertical engine at one end by means of an endless rope about 700ft. long, and Russell's patent arrangement of driving pulleys, which all revolve in the same direction, and avoid reverse bends in the rope. This crane has done efficient service in placing the heavy exhibits. Messrs. Russell have also an 8-ton portable steam crane on an ordinary railway gauge, which was used in the goods yard for unloading the general heavy exhibits as they arrived, and will be again in operation after the close of the Exhibition in loading them for removal.

The boilers for supplying the steam for the engines are nine in number, 28ft. long by 7ft. 6in. in diameter, and work at an average pressure of 100lb. per square inch. They are all of the Lancashire type, and are good specimens of substantial work, but present no novel features of construction. They were made and supplied on loan by Messrs. D. Adamson & Co., Manchester; Messrs. A. and W. Smith & Co., Messrs. Wm. Wilson & Co., Messrs. Penman & Co., Glasgow; and Messrs. Sinclair & Co., Leith. Of those by Messrs. Wm. Wilson & Co., one is fitted with Tenby's patent flues, Redgate's patent triplex fire bars, and Schallehu's patent smoke consumer, and the other with Proctor's mechanical stoker and self acting fire bars. The steam pipes have a total length of about 2200ft., and range in diameter from 15in. downwards, and are chiefly run in underground culverts, branches being taken off where the steam pressure is required. The engines for driving the machinery are four in number, and have been supplied by Messrs. Mirrlees, Watson, and Co., Messrs. Alley & Maclellan, both of Glasgow, and Messrs. John Cochrane & Co., Barrhead, and which we shall notice in detail on a future occasion. We have already (see *Industries*, Vol. IV., page 396) given a description of the electric lighting plant and a few particulars of the engines which supply the power, and will give further details later on.

If visitors enter the Exhibition by one of the main entrances under the dome, and proceed along the main avenue till they come to the west side of the machinery court, they will find a flight of steps leading to a gallery, from which a good survey of this section of the Exhibition can be obtained. It passes through the boiler house, along the front of the boilers, into the dynamo shed, and along three sides of the machinery court. Starting then from the boiler house, we look down upon the whole of the boiler arrangements, while from the side gallery we can see at a glance the whole of the electric lighting plant, of which a plan is given at page 396 in the present volume. Entering the gallery on the west side of the court, at its lower end we see a magnificent collection of steel castings and forgings by the Steel Company of Scotland, David Colville & Sons, Hadfield's Steel Foundry Company, Sheffield; Charles Cammell & Co., Sheffield; John Brown & Co., Sheffield; William Beardmore & Co., Parkhead, Glasgow, as well as by other firms; while cast iron work is represented by Walter Macfarlane & Co., of the Saracen Foundry, Glasgow, and George Smith & Co., of the Sun Foundry, Glasgow. On the right of these collections is a working bakery by Robert Thomson & Son, Crossmyloof, Glasgow, in which the manufacture of biscuits by machinery is practically shown. Alongside the gallery is a collection of machines for making confections of all kinds, which receive a considerable amount of attention from the younger visitors. The Pulsometer Engineering Company, London, show a large number of pulsometer steam pumps of various sizes—from No. 1, throwing 900 gallons per hour, to No. 10, throwing 52,000 gallons per hour—as well as a considerable number of other kinds of pumps. Thomas McCulloch & Sons, Kilmarnock, show a high pressure horizontal steam engine, fitted with Pröell's patent variable automatic expansion gear. Napier Brothers show various forms of their well known windlass, and various other ingenious appliances; while Messrs. Brown Brothers & Co., Edinburgh, have their various hydraulic appliances. Different sizes of Rigby's patent double acting steam hammers are exhibited by Messrs. Glen & Ross, who also show a novelty in the way of rotary engines, in a specimen of Ross & McDowell's patent high speed "Rota" engines, of which we hope to give an illustrated description later on. Passing along the north side of the gallery, we see the main exhibits in the centre of the court. The most striking are those by Messrs. Mirrlees, Watson, and Co., Scotland-street, Glasgow. The principal feature of the exhibit is a new form of sugar mill recently designed and patented by the firm. Among the other exhibits of Messrs. Mirrlees, Watson, & Co., are one of their diagonal engines and a steam pump. Messrs. A. & P. Steven, Provanside, have a selection of their hydraulic appliances, all of which exhibit good design and workmanship. Messrs. Alley & Maclellan show several Westinghouse engines, and specimens of their steering and hoisting gear, and of their steam and water valves, which maintain the reputation of the firm for careful work. There are a very large number of specialties, too numerous to mention at present; but the following collections may be indicated as worthy of attention, viz., those by Archibald Baird and Son, J. & G. Weir, Clark, Chapman, Parsons, & Co., Fielding & Platt, Greenwood & Batley, Lancaster and Tonge, and Dempster, Moore, & Co.

Messrs. Ross & Duncan show a set of small triple expansion engines, with Bremmé's valve gear for reversing and varying expansion, and they are the only full sized complete marine engines in the Exhibition. There are several large trophies made up of iron and copper tubes, which illustrate the progress made in these departments during recent years. Then there are very good representations of machine and hand tools by Sharp, Stewart, and Co., Dron & Lawson, A. Mathieson & Son, and others which are well worthy of careful study. Leather manufacture and the industries connected with it are well represented, the most notable examples among the former being those by John Tullis & Son, and Caldwell, Hamilton, and Sons, and the latter by R. & J. Dick and W. & J. Martin. Facing the north end of the court there is a large patent Axminster Brussels power loom for the production of special heavy back carpets, and along the court there are a large number of looms and appliances connected with the textile industries. Passing along the gallery on the east end of the court we see one of the most complete collections of printing machinery ever shown in an exhibition, and all of which is in operation. Along and under the galleries we have traversed there are a very large number of smaller exhibits, which are well worthy of special study.

We have now made a rapid survey of the machinery court proper; but in order to give a little more accommodation, an addition has been made on the other side of the main avenue, which is chiefly devoted to exhibits connected with heating, lighting by gas, and cooking. There is, however, a very good exhibit of gas engines by Messrs. Crossley Brothers, who show fourteen specimens of the "Otto" type. There are also specimens of the "Stockport" and "Sturgeon" engines in the same room, while in other parts of the building are to be found the "Griffin," the "Acme," and other kinds, which we intend to notice more at length shortly. In the meantime we have simply taken a rapid survey of some of the more important features of this part of the Exhibition, and we can say that its leisurely study will be amply repaid.

Telephony.—The subscribers to the Madrid Telephone exchange now number 2500, which is remarkably many, considering that the charge is high, and that it is not a business city. Applications, however, continue to come in, and the company has found it necessary to increase its capital to £64,000. The Spanish Government offers the concession of the telephone system of Carthagena. The latter town is a large business place, and contains a government arsenal.

SOME RECENT OFFICIAL REPORTS ON BOILER EXPLOSIONS.

Report No. 255 refers to the explosion of a small vertical boiler, 2ft. 7½in. diam., on board the trawl boat "Pilot," 58 tons register, about midnight on the 5th January, at the east end of the Silver Pits, in the North Sea. The boat was owned and sailed by James Tight, Cliff Cottage, Gorleston. The fire box is stated to have been 2ft. 2½in. diam.—height not given—and was connected to the top of the boiler by an uptake 8in. diam. It was provided with the usual mountings, all in good working order; the safety valve being 2in. diam., and loaded to 80lb. per square inch. The plate forming the uptake was corroded through from internal corrosion a little above the water line, and according to the report a small opening, 1in. in length and about ⅛in. wide, was formed, and "through this small aperture" the steam escaped. The skipper stated that "he heard a hissing noise, and found that steam was escaping up the funnel; he had heard a similar noise, though not so loud, on the previous day, but did not notice the escape of steam. He continued to fire the boiler until the engine was no longer able to work the capstan."

Report No. 256, which deals with the bursting of some tubes in the main boiler of the "Gipsy Queen" steamship, of West Hartlepool, calls for no special description, as it simply relates to the giving way from ordinary wear and tear, at different times, of eighteen tubes of an ordinary cylindrical multitubular boiler, causing no unusual inconvenience beyond leakage on one occasion sufficient to lower the water beyond the range of the indication of the gauge glass. It may be doubted whether official inquiries were necessary in the above cases. It does not appear to us requisite to make an inquiry into every case of nominal explosion that may be reported to the Board of Trade under the Boiler Explosions Act, and these would appear to be cases where the Board of Trade might well have used its discretionary power in relation to the holding of such inquiries.

Report No. 257 is interesting for two reasons, first, because it refers to an explosion which only occurred on the 3rd of February last, showing an improvement in the rate of reporting upon these accidents; and, secondly, because it affords some insight with reference to the varied formulæ used by the Board of Trade for the calculation of the strength of vertical boiler fire boxes. The boiler in question was the property of Mr. J. C. Roberts, timber merchant, Dolgelly. It was of the ordinary vertical type, 9ft. 5in. high, 4ft. 6in. diam., with the top dished 2¾in. The fire box was 6ft. 5in. high, 3ft. 11in. diam., with the crown dished and connected to an uptake 11in. diam. All the plates as new were ⅜in. thick, single riveted and lap jointed. Three cross tubes 10in. diam., with flanged ends, were fixed across the upper part of the fire box. The mountings consisted of one open safety valve 2½in. diam., loaded by a lever and movable weight to 107lb. per square inch; one glass water gauge, two test cocks, one steam gauge graduated to 80lb., one steam stop valve, and also a feed valve, blow-off cock, and steam whistle. The boiler was made by Messrs. Barrows and Stewart, Banbury, in 1874 or 1875, and had only once been repaired, by fitting a new crown to the fire box. The fire box was found collapsed on the right hand side nearly the entire height, and a rupture had occurred through the solid plate near the cross seam at half height, forming an opening 18in. in length and 3ft. in width. The boiler was thrown into the air, and fell about thirty yards away, without doing injury to any person. The report states that the explosion happened "because the fire box had been gradually deteriorated by corrosion until it became no longer fit to support the ordinary working load. The plate at the fractured edge is only ¼in. thick, which, taken in conjunction with the diameter and the length of the fire box, is altogether inadequate for a pressure equal to that on the safety valve, viz., 107lb. per square inch. If the thickness of the fire box be taken at ¼in., the collapsing pressure by Sir Wm. Fairbairn's formula is 175lb. per square inch, which is 2·18 times the maximum working pressure according to the evidence, and 1·63 times the pressure per square inch, to which the safety valve was loaded." To the report is appended the following remarks by the Engineer Surveyor in Chief: "This is another explosion brought about by working a boiler at a pressure for which it was unfit. There are still engineers who profess to credit vertical furnaces, such as the one which has collapsed in this instance, with possessing a much greater power to resist collapse than they frequently prove themselves to possess. There appears to have been no efficient inspection made of this boiler, and its explosion, under the circumstances named in the report, is nothing but what might have been expected."

It is somewhat singular, however—particularly in connection with these latter remarks—that no reference is made by the Engineer Inspector or by the Engineer Surveyor in Chief to the collapsing pressure of the fire box by the Board of Trade formula, as used for a similar type of boiler in Report 145. It appears that, taking the thickness of the plates at ⅜in.—the thickness when the boiler was new—the collapsing pressure by that formula would only be 107lb.; and, assuming the plates to be only ¼in. thick—as taken by the Board of Trade Inspector—only 48lb. per square inch! In view of the boiler having safely worked for thirteen or fourteen years with the safety valve loaded to 107lb. per square inch, some explanation should, we think, be given of this bewildering discrepancy between actual practice and the results obtained by this formula.

THE LATE SIR CHARLES BRIGHT.

At the meeting of the Society of Telegraph Engineers and Electricians on the 10th inst., the President, Mr. Graves, referred in sympathetic terms to the death of Sir Charles Bright. He pointed out that while Mr. Crampton, whose death was announced at the previous meeting, had designed the first submarine cable, Sir Charles Bright had designed the first Atlantic cable. This cable had, it was true, but a short life, owing to faults of construction and other circumstances; but it showed what could be done, and the experience gained was of the greatest value to all who subsequently laid submarine cables. Sir Charles had also invented the bell telegraph and other apparatus, and he had greatly assisted in the development of submarine telegraphy. The President concluded by moving that the Society should express its sympathy with Lady Bright and the other members of his family, and the resolution was carried unanimously.

SHIPBUILDING NOTES.

The s.s. "Athenian," belonging to Messrs. Leyland, Liverpool, has recently been fitted with new machinery, so as to enable much higher pressure to be used than formerly. The cylinders have been reduced from 34in. and 68in. diam. to 22½in. and 60in. diam. respectively; but the boiler pressure has been increased to 150lb. per square inch. A trial trip was made last week, when, with a piston speed of 402ft. per minute, or 67 revolutions, 980 i.h.p. was developed. The vessel obtained an average speed of 11 knots per hour.

On the 4th inst., the new steel steamer "Engineer" had a successful trial trip. The vessel was loaded with full cargo, and attained an average speed of 11½ knots per hour. The "Engineer" was built by Mr. James Laing, Deptford Ship Yard, Sunderland, to the order of Messrs. Tatham, Bromage, & Co., London, and is specially designed for carrying machinery, having exceptionally large hatches, and appliances for lifting great weights. The dimensions are: Length between perpendiculars, 200ft.; breadth moulded, 28ft.; depth moulded, 15ft. The engines and boilers are by Mr. George Clark, Southwick Engine Works, Sunderland. The cylinders are 18in., 38in., and 53in. diam., with 24in. length of stroke.

Messrs. C. S. Swan & Hunter launched from their shipbuilding yard at Wallsend-on-Tyne, on the 7th inst., the screw steamer "Gellwara," which has been built to the order of the Anglo-Scandinavian Steamship Company. The vessel is of the following dimensions: Length between perpendiculars, 330ft.; breadth moulded, 45ft.; depth moulded, 24ft. 3in.; and is built of Siemens-Martin steel on the spar deck principle, with cellular double bottom, with extra strength beyond the requirements of Lloyd's Register for the 100 A class. The vessel has a cargo capacity of 4000 tons, and will be able to carry 3300 tons on the exceptionally light draught of 17ft., and attain a speed of 11½ knots per hour. The "Gellwara" is provided with twin screws, and has two sets of triple expansion engines, 18in., 28½in., 46in. diam. of cylinders, 33in. length of stroke, indicating 2000 h.p. The boilers and engines have been constructed by the Wallsend Slipway and Engineering Company, Limited, Wallsend-on-Tyne. The deck machinery consists of four double horizontal steam winches, and two special 20-ton derricks to facilitate loading and discharging, steam steering gear, and direct steam windlass. In addition to the usual oil lamps, the vessel will have a complete electric light installation, including large deck lamps, to expedite loading and discharging at night time, as well as a powerful arc search light.

CONVERSAZIONE AT THE ROYAL SOCIETY.

The first Royal Society conversazione of the season was held at Burlington House on the 9th inst., and was largely attended. Amongst the more remarkable exhibits we noticed a new instrument, by Captain Abney and Major-General Festing, for the measurement of light reflected by coloured pigments. The object of this instrument is to define, in a scientific and accurate way, the shade and depth of any colour, so that it may be reproduced at any future time. The colour to be defined is compared with that portion of a spectrum with which it coincides, and for this purpose a beam of light from an arc lamp, after passing through a narrow slot, is split up into two spectra, one of which falls upon a white screen, whilst the other falls upon a screen painted with the pigment to be investigated. By a suitable slide, the position of which can be read off on a scale, only those rays of the spectra are utilised which correspond with the colour of the pigment. To match the depth of colour there is interposed in one of the rays a metallic disc, with openings which can be more or less closed. This disc is revolved at a constant speed by means of an electromotor, and the size of the openings is varied whilst the disc is in motion until the colour has been matched. The proportion of the openings to the total circumference of the disc and the position of the slide before mentioned, give together an exact indication of the colour of the pigment, and a diagram can then be prepared for future use. In the same room Professor Rücker and Mr. Boys exhibited their beautiful experiments on electrical stress, which we have already noticed in our issue of the 30th March. There was also exhibited a large Wimshurst machine containing twelve discs of 2ft. 6in. diam., each disc carrying sixteen metal sectors. It was used to show a perfect brush discharge at its terminals, and when used with Leyden jars produced a spark 13½in. long. A very beautiful display of flashes could be seen on the outside of the Leyden jar, which was only partly coated. Mr. Boys showed a radio-micrometer, which is a very delicate instrument for measuring radiant heat. It consists of a circuit made of antimony, bismuth, and copper, hung by an exceedingly fine fibre of quartz in a strong magnetic field. The fibre is so fine that, when magnified twenty times, it appears only to have the same thickness as spun glass. The same gentleman also exhibited some interesting experiments with soap bubbles, most of them intended to show that there is a strong force of repulsion between the thin films of soap bubbles owing to which it is impossible to bring them into actual contact. The outer of two bubbles may be pulled out until it squeezes the inner one into a long oval without real contact taking place, and an inner bubble filled with hydrogen will carry up the outer one to which is attached a weight; yet the surfaces of the two bubbles do not touch.

In the reception room there was exhibited a series of maps and diagrams illustrating the recent work of the Geological Survey in the North-West Highlands of Scotland, and Mr. Caddel, of Grange, a member of the Survey, showed some interesting photographs, illustrating experiments made with a view to account for the remarkable dislocations found in that district. Most geologists have hitherto supposed that the earth's crust, when locally subjected to horizontal pressure, behaves like a plastic mass, and bends into great folds like a piece of carpet. The recent survey shows, however, that this is not necessarily the case. The crust seems to have behaved more like a rigid and brittle mass yielding to pressure by snapping asunder, the broken pieces being thrust one upon the other. Mr. Caddel has reproduced this phenomenon in the laboratory by putting pressure on brittle stiff strata composed of damp sand and plaster of paris. The artificial rock thus produced solidified *in situ* by the plaster absorbing moisture from the sand, and formed stiff lamina between the softer sandy base. When pressure was applied by means of a screw, the strata snapped, and parts of the mass slid over other parts in thrust planes, producing structures exactly like those found in the western borders of Sutherland and Ross. There were some thirty or forty photographs of these experiments exhibited. Mr. Caddel also showed how the so-called fan structure found in the Alps might be imitated in the laboratory.

In the principal library we noticed an apparatus by Mr. Thomas Turner for the determination of the hardness of metals or other substances. This consists of a balance arm, to the longer end of which is attached a diamond. A sliding weight on the arm determines the pressure exerted by the diamond upon the specimen under test when the surface of it be scratched. A series of scratches is made with varying pressure, and that scratch which can just be felt is compared with certain standard scratches, and thus the degree of hardness is determined. Professor George Forbes exhibited his coulomb meters, which were worked by a secondary battery. As we have already described these delicate instruments when reporting the last meeting of the British Association, we need not give a detailed description in this place beyond mentioning that a ring of india-rubber has been inserted into the glass bell near the bottom of the instrument for the purpose of eliminating the disturbing influence of convection currents. Mr. Eric Stuart Bruce exhibited a model of his translucent balloon for military signalling at night. Within the balloon is fixed a ladder containing about half a dozen glow lamps, and in addition to the cable by which the balloon is kept captive there is a twin conductor joining these lamps with a battery and a switch on the ground by which Morse signals are transmitted. Messrs. Johnson, Matthey, & Co. exhibited some incandescent gas burners, the mantle of which is made of iridium-platinum gauze. The light from these

Digitized by Google

lamps is not so white as from the Welsbach burner; but the makers claim that the difficulty of very fragile mantles is entirely overcome by their invention. Mr. Shelford Bidwell exhibited his apparatus for measuring the change produced in the length of rods and rings by magnetisation, a detailed account of which will be found on page 377 in our issue of the 13th April. Messrs. Woodhouse & Rawson showed Vernon Harcourt's new pentane standard lamp, which has a naked flame, and is, therefore, free from the objection of the varying absorption of light by a glass cylinder. There was also a photometer arranged for the rapid determination of the light given out by a glow lamp in all directions. The new microphone carbon button, and the filaments of adamantine carbon exhibited were interesting, as showing how carbon can be artificially manufactured to a degree of hardness which brings it very near to that of black diamonds. The Edison & Swan United Electric Light Company showed some of the most recent forms of Swan's safety lamp for miners, which weighs 7lb., and is 7in. high by 4¼in. diam. These lamps, which are intended for use by the overseers, are provided with a new fire damp detector, consisting of a circular metal box, with a glass cover attached to the side of the lamp. Within this box is stretched a platinum spiral, and when turning the outer rim of the box into a certain position communication is established with the atmosphere. Upon further turning, the communication is interrupted, and the current from the four storage cells is switched on. The platinum wire begins to glow, and if there be fire damp in the atmosphere, the characteristic blue light appears. There were also some Schanschieff safety lamps exhibited.

On the ground floor Professor Kennedy exhibited for Mr. Baker some lantern views, illustrating the progress made in the erection of the great cantilevers spanning the 1700ft. wide openings of the Forth Bridge. Mr. Arthur Sopwith exhibited lantern views of the interior workings of a colliery. These were the same views which Mr. Preece recently showed at the Royal Institution. Dr. Mariet showed the image of electric sparks on a screen magnified by a camera lens, in illustration of flashes of lightning.

THE PHYSICAL SOCIETY.

At the last meeting of this Society, Professor S. P. Thompson read two notes, one dealing with the condition of self excitation of a dynamo machine, and the other with that of self regulation for constant potential difference. The author, after referring to a previous paper read by him before the Society, in which he had dealt with the question of dead turns on the basis of the Lamont-Fröhlich formula, said that in the present investigation he made no assumption whatever about the law connecting magnetising force and induction. The electromotive force developed in the armature is proportional to NCu, where N represents the total induction, C the number of armature conductors, and u the number of revolutions per second. The current is given by the expression $\frac{NCu}{a+x}$ where a is the internal resistance of the machine, and x the resistance of the external circuit. If the field magnets are wound with S turns of wire which are traversed by the current i the induction is represented by the formula

$$N=\frac{4\pi Si}{R}$$

where R, the magnetic resistance, consists of a portion α due to the air gap, and ξ due to the iron. By inserting this value for N into the formula for the e.m.f. we obtain

$$4\pi uCS=(\alpha+\xi)(a+x)$$

as the condition of self excitation for a series machine. A similar formula was given for the shunt machine. From the above formula it will be seen that for every given speed there is a limiting value x_1 of the external resistance x, beyond which the machine will refuse to excite itself. Neglecting ξ, which is very small for the initial stages of magnetisation, this limiting value is

$$x_1=\frac{4\pi uCS}{\alpha}-a.$$

In the discussion which followed, Mr. Kapp pointed out that the subject so clearly put forward by the author was not new, the critical conditions of dynamos being well known to the makers of these machines. His own practice, after the usual test, was to run his machines on the shunt only at the minimum speed at which they would excite, and noting the ratio of speed to voltage, which remained constant over a certain range of speed. This gave him the minimum value of $(\alpha+\xi)$, which he called the critical magnetic resistance, and which he invariably found to be lower than the theoretical value α of the air resistance only. The theoretical value of the air resistance was obtained by multiplying the co-efficient 1860 with double the air gap, and dividing by the polar area, the latter increased by a fringe equal to half the air gap. Experiment, however, showed that the co-efficient should be taken at 1440, and not at 1860, and this the speaker attributed to the permeability of copper being slightly greater than that of air, an explanation first suggested to him by Professor Ewing. A modification was also introduced by a certain tendency dynamo machines have to continue in their condition of excitation, or non-excitation, as the case may be. Although a machine may not start on a high resistance, it might be ultimately made to work through that resistance if started with a lower resistance, which would gradually be increased.

Professor Perry suggested that this might possibly explain why the air resistance, instead of being represented, as is done in Dr. Hopkinson's curves, by a straight line through the origin tangential to the characteristic curve, was really represented by a straight line through the origin intersecting the characteristic.

Professor Ayrton said that the author's formulæ could not be directly applied to determine the critical speed and resistance: first, because no account was taken of residual magnetism, which produces an e.m.f. of 3 or 4 volts at ordinary speeds; and secondly, because a, the internal resistance of the machine, is not a constant, as was assumed. The variation is due to the self induction of the armature, which is considerable for small currents, and to a kind of spurious resistance between the brushes and the commutator, which may possibly be due to jumping. He had often found that a dynamo could be made to excite itself at a lower speed than it otherwise would by pressing the brushes against the commutator, showing the existence of the resistance to which he had referred.

Lord Rayleigh pointed out that the fact that no current was produced below a certain speed had been very simply explained by Sir William Thomson many years ago. His reasoning was based on Faraday's dynamo, a revolving copper disc touched by conducting wires at its centre and circumference, and he also showed that above a certain speed a state of instability ensues. The reason that no definite speed can be determined is that the work done against e.m.f. is proportional to the square of the current, and so is the work spent in the circuit, so that the two balance each other. He did not like the term "magnetic resistance," as this term was generally used where there was work absorbed. In the case of magnetic resistance there was no work absorbed.

Professor Thompson, in reply, stated that he was not oblivious of Sir William Thomson's paper, which formed the foundation for the study of critical velocity. He had noticed that a machine could often be started by taking off and putting on the brushes. He agreed with Professor Ayrton that the internal resistance of the machine was not a constant, and had only treated it as more or less approximately so. The reason that α was not constant was due to the great variation in the magnetic resistance of iron in its lower stages of magnetisation. He thought that the difference observed by Mr. Kapp was due to an insufficient allowance made for the fringing of the magnetic field. The slight residual magnetism would make no practical difference.

The other note by Professor S. P. Thompson, on the condition of self regulation in a constant potential dynamo machine, was an attempt to make a certain formula, published by the author some time ago, agree with practical results. This formula was originally given as follows:—

$$\frac{Z}{S}=\frac{r_a}{r_a+r_m}$$

in which Z and S signify turns of wire in the shunt and main coils respectively, and r_s, r_a, and r_m are respectively the resistances in the shunt, armature, and main coils.

In a machine tested by Fröhlich, he had found $\frac{Z}{S}=17{\cdot}7$ and $\frac{r_a}{r_a+r_m}=64$. This was clearly a very badly constructed machine. The formula could, however, be made to fit any moderately well designed machine by writing it thus:—

$$\frac{Z}{S}=\frac{r_a}{r_a+r_m}\frac{q_0}{q_1}$$

where q_0 and q_1 represented certain co-efficients depending on the configuration of the magnetic circuit.

There was no discussion.

Mr. Blakesley then brought forward his views on

Magnetic Lag,

and the loss of power accompanying the reversal of polarity in an iron core subject to the influence of harmonic currents. On other occasions Mr. Blakesley has given formulæ for determining the lag in transformers, and for calculating the loss of work incidental to it; but in this paper the methods of calculation were for the first time given. A dynamometer is placed in each circuit, and a third has one of its coils in each circuit. These furnish without difficulty the current, and therefore the magnetising stress produced thereby in each coil, and the angle of phase difference between them. The resultant magnetising stress is therefore known, and the phase relatively to each component. If this resultant is in quadrature with the current in the secondary, there can be no magnetic lag, for the magnetism must be in quadrature with that current. But experiment shows that the magnetic stress is in advance of the magnetism from 5° to 6°. If this angle of advance be represented by φ, then—

$$\tan\varphi=\frac{\frac{m}{n}C\alpha_3-B\alpha_2}{\frac{m}{n}\sqrt{AB\alpha_1\alpha_2-C^2\alpha_3^2}}$$

where m=the number of turns of wire on the primary coil; n=the number of turns of wire on the secondary coil; A B C are the dynamometer constants; and α_1 α_2 α_3 are the dynamometer readings.

The dynamometer constant is that number which, multiplied by the reading, will give half the square of the maximum value of the current. Thus the existence of a magnetic lag may be detected by the use of the second and third dynamometers alone, and measured by means of the three together. Further, as the current induced in the secondary coil is known, the e.m.f. of this induction can be easily calculated if the resistance r_2 in that coil is also known. This e.m.f. per turn is $\frac{I_2r_2}{n}$, I_2 being the secondary current. But this must also apply to the coils of the primary. Therefore, $\frac{m}{n}I_2r_2$ is the whole induced e.m.f. in the primary, and $\frac{m}{n}\frac{I_2r_2}{r_1}$ must be the induced component of the current in the primary coil; and consequently $\frac{m^2}{n}\frac{I_2r_2}{r_1}$ is the magnetic stress arising from it, and forms one of the components of the whole magnetic stress due to the current in the primary coil. Their difference of phase being known, the remaining component due to the e.m.f. (E) of the machine itself, viz., $\frac{E}{r_1}m$, becomes known.

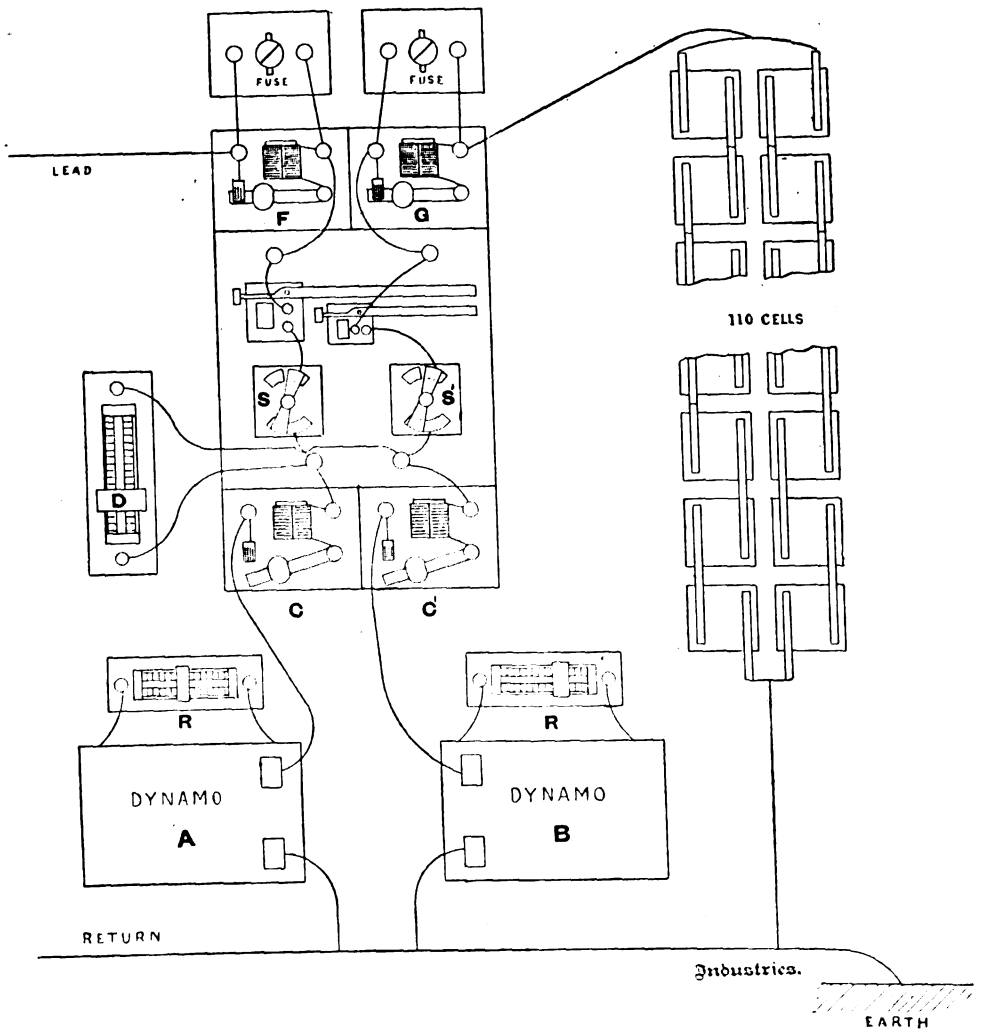
All these vectorial quantities can be plotted geometrically in a way with which Mr. Blakesley has endeavoured in other papers to make electricians familiar, so that the work done and other matters become functions of a simple triangulation, the sides of which merely involve dynamometer readings and constants, the resistances in the circuits, and the number of turns of wire in the two coils. The whole work done by the machine takes the simple form:—

$$r_1A\alpha_1+r_2\frac{m}{n}C\alpha_3.$$

The first term is obviously the power heating the primary coil. The second term is the sum of the power heating the secondary coil r_2 $B\alpha_2$, and the power involved in the magnetic reversals; it follows that the latter is equal to

$$r_2\left(\frac{m}{n}C\alpha_3-B\alpha_2\right)$$

which contains as a factor the numerator of the expression for the tangent of the lag, and showing that one is the result of the other.



In speculating upon the cause of the lag, Mr. Blakesley believes that the increasing magnetisation calls into being an opposing magnetic stress, as motion in a medium calls into being an opposing friction. This induced magnetic stress must be compounded with those impressed by the currents to obtain the effective magnetic stress which is in phase with the magnetism. This involves the conception of magnetic self induction, and a corresponding co-efficient symbolised by N, to which Mr. Blakesley is careful not to attribute constancy, though he points out that its constancy is a necessary condition to the maintenance of the harmonic character of the changes. These views were illustrated by experimental results.

After the reading of this paper,

Professors Ayrton and Perry showed some interesting applications of their magnifying spring. The first of these was a lecture apparatus designed to exhibit the expansion of metals by heat, and consisted essentially of a magnifying spring, with one end fixed and the other attached to the free end of the expanding bar, the spring carrying a pointer, which rotated over a dial as the bar expanded. An aneroid barometer was also exhibited, in which the expansion of the metal chamber was shown by a magnifying spring carrying a pointer, in place of the ordinary somewhat complex mechanism of wheels and pinions. An arrangement was also exhibited in which, by a combination of two portions of a spring wound on a large mandrel with one wound on a small one, a small rotation could be magnified into a large rotary movement.

ELECTRIC LIGHTING AT THE "SCOTSMAN" OFFICES.

ELECTRIC LIGHT INSTALLATION AT THE "SCOTSMAN" OFFICES.

THE proprietors of the leading Scotch newspaper, fully appreciating the advantages of electric lighting, began about eighteen months ago to introduce glow lamps in some portions of their establishment; and since then they have gradually extended the installation, until now nearly the whole of their offices and printing works are lighted electrically. The installation comprises about 370 glow lamps, of 16, 32, and 50 c.p., current being supplied by two 300-light dynamos, driven by belting from an ordinary horizontal engine, and in conjunction with the dynamos there is installed a storage battery of 110 cells, capable of supplying upwards of two hundred lamps. The installation is interesting on account of its having been carried out on the single wire or earth return system, and also because of the ingenious manner in which the dynamos, cells, and line are coupled up. Referring to our diagram, the dynamo A supplies current at 110 volts direct to the lamps, whilst dynamo B supplies a charging current of 137 volts to the cells, and it may at the same time assist the other dynamo in lighting. The pressure at the terminals of both dynamos is adjusted separately by the shunt rheostats R, shown in our sketch. The current from dynamo A passes through a differential magnetic cut-out C, then through the switch S and a steelyard ampère meter to a second magnetic cut-out F, and then to the line. Parallel with the magnetic cut-out, is coupled a fuse containing a high resistance, so that if, owing to a heavy leak, the magnetic cut-out F should come into action, the current to the lamps is not completely interrupted, but is reduced by that resistance to such an extent as to avoid danger. The resistance is, however, so adjusted that should the magnetic cut-out F act on account of an absolute short circuit, then the fuse itself will also melt. The connections from dynamo B are similar. The current passes first through the differential magnetic cut-out C^1, then through the switch S^1, through a steelyard ampère meter, through a second magnetic cut-out G, to which is connected in parallel a second fuse with resistance, and then to the positive terminal of the cells. The negative terminal of the cells is in connection with the earth return. Between the switches S and S^1 is inserted a variable resistance D of sufficiently stout wire to take that portion of the current from dynamo B which it is intended to send direct to the line. The quantity of current thus supplied to the lamps from dynamo B depends upon that portion of the contact D. The more current is to be sent directly to the lamps from dynamo B, the less must be the resistance of this rheostat. By its means it is also possible to stop dynamo A, and to charge and light simultaneously, from dynamo B, the rheostat, serving to reduce the pressure from 137 volts at the dynamo to 110 volts at the lamps. Usually the cells are charged at night, when the maximum number of lamps is on, and both dynamos are at work. In this case the current from dynamo B is mainly used for charging, and that from dynamo A exclusively for lighting; but by the interposition of the rheostat D, the lighting circuit gets the advantage of the steadying influence of the batteries, so as to tone down the effect of any irregularity which might exist in the speed of the dynamo. In the daytime there are seldom more than about forty lamps on, and these are usually supplied from the batteries, the dynamos being at rest. If it should be desired to charge the batteries in the daytime whilst lighting, only dynamo B is used, and the resistance of the rheostat D is suitably increased; but the loss of energy occasioned thereby is small, on account of the small current passing to the line. The construction of the magnetic cut-out is indicated in our diagram. When the current and pressure are within proper limits, the switch lever is held closed by a catch controlled by the armature of a differential electromagnet, which in this case is not energised sufficiently to attract its armature. Should the current or the pressure increase, the armature is, however, attracted, the catch is released, and the lever falls by its own weight, thus breaking the circuit. The same result occurs if the main current ceases to flow through the magnet, because in this case the magnetising power of the shunt current, acting alone, is sufficient to attract the armature, and thus cause the cut-out to act. In this way a back flow of current from the batteries to the dynamo is avoided, in case the latter should accidentally stop.

As we have already mentioned, this installation is carried out on the earth wire system. The positive wire is well insulated, but the return wire is connected to the brass work of all the fittings, and to the main water and gas pipes. All the switches and fuses are placed in the positive circuit. A switch and fuse are fitted in a box to control each sub-main which lights a department, and a fuse is placed in the base block, and a switch in the brass work of each fitting. The installation has been erected under the superintendence of Mr. J. D. F. Andrews, partner in the firm of Messrs. Muir, Mavor, and Coulson, of Glasgow.

FIRE RISKS IN ELECTRIC LIGHTING.

AT the meeting of the Society of Telegraph Engineers and Electricians, held on the 10th inst., Mr. W. H. Preece, F.R.S., read a paper on "The Risks of Fire Incidental to Electric Lighting." The author began by pointing out that the practical applications of electricity involved serious danger when proper precautions were neglected. These dangers, however, could all be avoided. All artificial illuminants gave rise to danger, but of these the electric light could most easily be rendered perfectly safe. In the year 1880 the author had sounded the note of alarm in a letter to the *Times*, in which some of these dangers were pointed out, and for this he was fiercely attacked by many of the promoters of electric lighting. It was, however, important to know the danger, as this knowledge led to suitable precautions being taken. The question then arose, whether rules and regulations for carrying out electric light installations were necessary. Such rules were not drawn up by the fire insurance companies with regard to other illuminants, because the precautions to be taken were self evident. As regards electric lighting, the author considered, however, such rules desirable, owing to the novelty of the subject, and the mysterious character of the agent used. Electricity could not be perceived either by sight or smell. It was also specially liable to fraud, as it was so easy to deceive the ignorant, and on this account afforded an extensive field for what Americans called "Cheap-Jackism." Rules and regulations were therefore also required to protect consumers from the rapacity of those who contracted to supply the light.

In the year 1881, the Edison Company of New York brought out a set of rules, and these were followed by a set drawn up by the fire insurance companies. In 1882 a set of rules founded upon these were drawn up by Mr. Heaphy for the Phœnix Fire Office, and in the same year another set had been drawn up by the Society of Telegraph Engineers and Electricians, and this example was followed by the Franklin Institute in America. The rules issued by the Society were simply assertions of general principles, and with respect to points of detail the majority of electrical engineers had been guided by the Phœnix rules, which were drawn up in the interest of the fire insurance companies. Last year it was suggested that the Society should revise the original rules, and since then fresh rules had been issued by three independent fire offices, whilst there was every prospect of other offices following suit. In the United States matters were still worse. The requirements of New York were met by the rules issued by the New York Board of Fire Underwriters, and revised from time to time. The rules of the Franklin Institute were in use at Philadelphia. At Boston at least two rival sets of rules were in force, and almost every town had a distinct set of rules in operation.

The original rules of the Society were in great demand, and with the exception of London installations, which were almost entirely carried out under the Phœnix rules, they were in use in the majority of electric lighting installations in this country Owing to this fact, and the desirability to revise these rules so as to bring them into accordance with modern requirements, the committee of the Society on the subject was re-appointed last May. The author did not approve of the matter being re-opened, as he was satisfied with the Phœnix rules: but ultimately he agreed to accept the chairmanship of the committee to which he had been elected, as he was in the case of the former committee. It was decided that in the first place the secretary of the Society should ascertain how far their action would meet with the support of the insurance companies, at the same time pointing out to them that the Society had no wish to take any action in the matter except in so far as they considered this desirable in their own interests. The companies expressed themselves in favour of some alterations being made in the rules, and of having, if possible, only one set of rules in use. The author considered that the committee ought to have the benefit of Mr. Heaphy's assistance, and accordingly Mr. Heaphy became a member of the Society and joined the committee. It was, however, found impossible to get the representatives of the different fire offices to agree among themselves. It was decided that the rules drawn up by the Society should be revised, and should, as before, deal only with general principles, and that they should be supplemented by detailed rules drawn up by Mr. Heaphy, and to be known as Fire Office Rules. Some objections were made by the author and others, chiefly to the phraseology of

Digitized by Google

the rules, as leaving too much to be decided by the fire insurance inspector. They came to an agreement regarding the abolition of these permissive clauses, and they also agreed to recommend, after due consideration and revision, the detail rules drawn up by the Phœnix Fire Office. Mr. Heaphy, however, wished them to adopt these rules *en bloc* before they had examined them, and upon their refusal he withdrew from the committee. The committee subsequently brought out their rules. The question was really one between the insurers and the insured, and all that the Society of Telegraph Engineers could do was to act the part of friendly guides. The committee was exceptionally strong. Among the leaders of science it included Professor W. G. Adams, Sir William Thomson, Professor Ayrton, Professor Cary Foster, Mr. Crookes, Dr. Hopkinson, and Professor Hughes. Among consulting electrical engineers it included Sir Charles Bright, Professor Forbes, Mr. Z. E. H. Gordon, and Mr. Massey, and among contractors Mr. Crompton and Mr. Alexander Siemens; the names of Professor Fleming and General Webber were also added.

The author pointed out that, in the interest of electric lighting, it was important to prevent such alarms of fire as occurred—for example, in Lord Brassey's house, where a transformer which had recently been fixed in position in an iron fire proof case, heated the case, and gave rise to an alarm, though no fire actually occurred. He also instanced the fire occurring at the Temple Theatre at Boston, by which that theatre was destroyed, and which originated in a short circuit in cotton covered wires insulated by paraffin. He also mentioned a fire which occurred at the Midland Works at Derby, due to a short circuit heating, and setting fire to one of the old wooden lamp holders. The author pointed out that while in 1887 the number of theatres destroyed by fires arising from the lighting system in use, averaged about two a month, the total number of fires arising from the use of the electric light during the same period was, after all, exceedingly small. Many of the sources of danger in electric lighting were of a nature which had never been anticipated—for example, in stables, the corrosive action of the ammonia upon the metal staples, and in houses, short circuits, arising from washing floors and the ravages of rats and mice, were all sources of danger which had to be provided against. It was a common practice, but one which could not be too strongly deprecated, to bury electric conductors in cement when houses were being built. Moisture was a great source of danger. In underground work water was a safeguard, as gutta-percha insulation is protected from decay when under water; but in the air both gutta-percha and india-rubber, when exposed to moisture and to changes of temperature, were very liable to deterioration. The wires were then attacked by electrolytic action until they became eaten away so much in some places as to be unable to carry the currents without undue heating. The practice of encasing wires in wood was an extremely dangerous one, and several fires in ships had arisen from this cause. Mercury contacts were most objectionable, except in positions where the mercury could be frequently renewed. Where the electric light was used in houses, the luxury and convenience of the light often led to additional lamps being placed on the original leads until the latter were unable to safely carry the current required, which led to their becoming heated, and forming a source of danger.

The greatest danger of all arose, however, from bad joints. All the older engineers would agree in maintaining that all joints should be soldered; yet the rules in force at Boston declared that "joints should be wrapped in tape, and though soldering is desirable it is not essential." Such a statement as this was, in the author's opinion, absolutely fatal to the value of the rules. According to the New England rules, resin should not be used as a flux in soldering joints, whereas Mr. Heaphy's rules advocated its use. The rules issued by the Society stated that where soldering fluids were used the joints should be carefully washed and dried before the insulator was applied. He preferred fluid to resin, except for submarine cable work, and considered Baker's fluid, which was generally used by the Post Office, a very good one. Loose connections of any kind were a great source of trouble, and joints should always be soldered where possible. Owing to defective joints, cut-outs, if not carefully looked after, were often a source of danger rather than of safety. Switches were often a source of danger owing to loose connections, and the author exhibited a switch which had been fixed against some oak carving in the House of Commons, and had very nearly caused a fire from heating, due to a loose connection. A great source of danger lay in the inflammable nature of the insulators in general use, and a good non-inflammable insulator was a great desideratum. The author stated that the Westinghouse Company were using Waring wires, which were insulated with a substance obtained as a distillate from petroleum after the naphtha and illuminating and lubricating oils had been given off. This substance was not so inflammable as other insulating compounds, and experiments were exhibited to show this.

ELECTRO-DYNAMIC ROTATION.

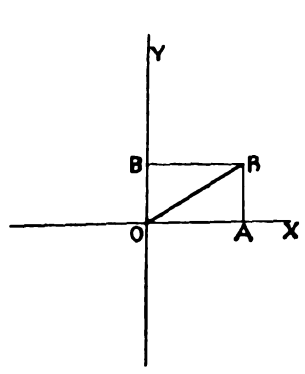

Fig. 1.

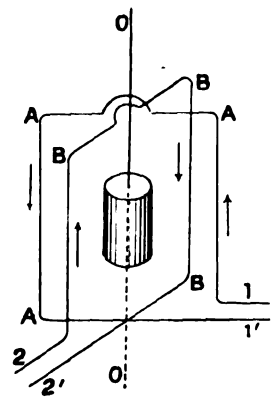

Fig. 2.

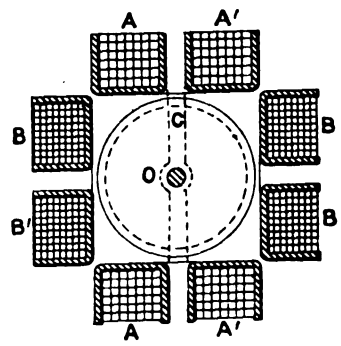

Fig. 3.

The author considers that the Phoenix Company had shown great pluck in accepting the risks on transformers before the majority of electricians had come to any conclusion on the matter. The Phoenix rules were extremely good, but not perfect, and he would like to see Mr. Heaphy join again in carrying on the work of revision from the point at which he had withdrawn his co-operation. One of the most effectual means of guarding against fire risks from electric lighting lay in the proper education of the rising generation of electrical engineers. It was essential to frame rules to exclude the cheap contractors who offered tenders at a price that could not pay for good work, relying on extras for their profits. Mr. Heaphy had stated that there had not been a single accident from fire arising from the electric light in installations carried out under his inspection and in accordance with the Phoenix rules, and the author believed this statement to be perfectly correct.

The discussion was opened by Mr. Heaphy, who thanked the author for the kind manner in which he had spoken of him, but took exception to the statement with respect to his reasons for withdrawing from the committee. He would give his account of the matter at the next meeting of the Society. He pointed out that when transformers were first introduced, and but little was known about them, the insurance companies were very chary about accepting risks upon them. The Phoenix Company decided to take the risks of admitting both transformers and high tension currents, under certain regulations, into buildings without any extra charge. Several electricians had told him, when he advised the company to this effect, that they would be sorry to be in his place, and that he was imperilling his professional reputation. These prophecies had, however, been falsified, as they had hitherto not had any accident either from high tension currents or transformers installed in compliance with their regulations. The speaker complained that after the Phœnix Company had taken all the risk the other fire insurance companies now wished to bring out their own rules. He stated that the Phœnix Company would be ready to meet the others in every reasonable way. The only real point of difference between himself and the committee had been his insistance on the retaining of the name "Phœnix" in conjunction with the rules.

Mr. Killingworth Hedges objected to the insertion of the word "copyright" after the Phœnix rules, as he maintained that they were practically identical with the rules previously published by Mr. Woodbury in America.

Mr. Human, surveyor of the Guardian Insurance Company, stated that they had issued a set of rules because they objected to send out lists of rules to their customers bearing the name of a rival company, thus advertising it at their expense. He hoped the action of the Society would ultimately lead to the adoption of one uniform set of rules, which would be accepted by all the insurance companies.

Mr. Swan called attention to cases of short circuiting arising from the trickling of water. He thought the earlier installations ought all to be overhauled, in order to detect bad joints and other defects. He agreed with Mr. Preece with respect to the importance of having all joints soldered, and thought this should apply even to the case of cut-outs.

Mr. John Verity made an appeal both to the Phœnix and to the other companies to endeavour to come to some definite arrangement, so that a single set of rules might be adopted. He pointed out that Mr. Heaphy had done great service to electric lighting, both by preventing fire scares, and by doing away with cutting competition by the stringency of the rules made by him.

Mr. Manville thought a few more contractors might have been added to the committee in addition to Mr. Crompton and Mr. Siemens.

Mr. Crompton considered that Mr. Heaphy's hard work, and the position which he had taken up from the beginning, gave him a moral, if not a legal, copyright in the rules. He was of opinion, based on the result of inquiries, that 95 per cent. of electrical contractors would be in favour of adopting Mr. Heaphy's rules. He thought it a pity that the Society should have to play the part of a buffer between the jealousies of rival insurance companies. The Phœnix Company were always ready to meet the wishes of contractors in a reasonable spirit, and as the great majority of the fire insurance offices were now using the Phœnix rules, he appealed to the other fire offices to lay aside their jealousy, and accept these rules.

Mr. Alexander Siemens considered that the principal defect of Mr. Heaphy's rules lay in the saving clauses occurring in nearly every rule, and which, he thought, left too much to the discretion of the fire insurance inspector, and this latitude might leave the way open for a less conscientious inspector than Mr. Heaphy to pass what might ultimately lead to danger. His own recollection of the point of difference between Mr. Heaphy and the committee of the Society coincided with the account given by Mr. Preece.

The discussion was adjourned to an extraordinary meeting on the 17th inst.

ELECTRO-DYNAMIC ROTATION BY MEANS OF ALTERNATING CURRENTS.

Professor Galileo Ferraris, of Turin, who, as will be remembered, was one of the first to make a strictly scientific investigation of transformers, and who has since then continued to devote attention to alternating currents, has just published the results of some experiments made with a view to produce continuous rotation by their means. The experiments are interesting, because the apparatus used was based upon an entirely new principle, which may be capable of further development. The question how to produce continuous rotation by means of alternating currents is just now occupying the minds of many electricians, because the production of an alternating current motor would greatly increase the earning capacity of central electric light stations supplying alternating currents. Whether the apparatus devised by Professor Ferraris, and which we are about to describe, will lead to the discovery of an alternating current motor, is a question on which we do not pretend to prophesy; but as the principle involved may also have other applications, notably in the construction of meters for measuring the supply of electricity, we think it of sufficient importance to lay a short abstract of the investigation before our readers. The principle on which the apparatus is based is exceedingly simple, and will be understood by reference to the accompanying sketches. Let in Fig. 1 the lines O A and O B represent in direction and magnitude the strength of two magnetic fields. The combined action of these fields on a unit pole, placed in the point O, would then be represented by the resultant O R. Instead of having two distinct fields, we have one resultant field, represented in direction and magnitude by this line. If both fields undergo periodic variations of the same period, the resultant field O R will also undergo a periodic variation, and the point R will traverse a curve, the form of which depends upon the precise manner in which the lines O A and O B change with the time. The fields O A and O B can be produced by two coils, having the lines O X and O Y respectively for their axes, and which coils are traversed by alternating currents of the same period. If the alternating currents may be expressed as sine functions of the time, and if there is an appreciable lag between the currents in the two coils, the point R describes an ellipse round O as centre. In

Digitized by Google

this case the line O R representing the resultant field revolves round the centre O, the direction and magnitude of the resultant field changing at every instant. If, however, there is no lag between the two currents, that is to say, if they pass through zero simultaneously, the direction of the resultant field O R remains stationary, and the point R performs harmonic oscillation over the line R O and its prolongation with O as centre. This may be considered as a special case of the ellipse where the latter has been flattened down to a mathematical line. Another special case occurs when the ellipse becomes a circle, and this must evidently take place when the lag between the two currents is 90°, when the coils are at right angles to each other, and when the component fields are equally strong. A metallic body suspended in the centre of the two fields, and free to revolve, must evidently have a tendency to participate in the rotation of the resultant field.

The application of this very simple principle will be clear from Fig. 2, in which the two coils are indicated by the rectangles A and B, the connections being made by the wires 1 1^1 and 2 2^1 respectively. When alternating currents are sent through these coils a resultant field is produced, which revolves round the line O O. In the centre between the coils is suspended a small hollow cylinder of copper, and as the lines of the resultant field cut the metal Foucault currents are induced, and by the interaction of these induced currents and the revolving field the cylinder is set in rotation. The action is exactly the reverse of that occurring in the well known experiment in which a copper disc is rapidly revolved below a compass needle, with the result that the compass needle is deflected on account of the induced currents in the copper disc, and ultimately caused to rotate with the copper disc.

Up to the present we have spoken of two distinct currents being required in the coils A and B, one lagging behind the other by a quarter period; and to perform the experiment we might employ an alternating current dynamo with two circuits in the armature, so arranged with regard to each other as to produce the desired lag. It is, however, possible to perform the experiment by using an ordinary alternating current machine with only one circuit on the armature, and to produce the second current by means of a transformer. The current from the machine is sent through the primary of the transformer and then through the coil A, whilst the secondary current obtained from the transformer is sent through the coil B. It is then possible, by the interposition of a suitable inert resistance into the secondary circuit, to obtain very nearly the desired lag of 90° between the currents in the two coils. As the strength of the secondary current will, by the insertion of the resistance, be considerably reduced, it is necessary, in order to obtain approximately equal fields from the two coils, to employ a larger number of turns in the coil B than in A. Another method of producing the desired result consists in using a transformer with one primary and two secondary coils, and to insert into the circuit of one of the secondary coils a large self induction, and into that of the other a large inert resistance, by which means the desired lag between the two secondary currents can also be obtained. It will be seen that in either of these ways it is possible, by means of a simple alternating current and a transformer, the coils of which are abreast, to obtain a revolving magnetic field of approximately uniform intensity, by which phenomena can be produced in every respect similar to those obtainable from a revolving permanent steel magnet.

In the first experiment made by Professor Ferraris, a Gaulard & Gibbs transformer, with an equal number of turns in the primary and secondary coils, was used. In the primary circuit was included the coil A, consisting of a few turns of stout wire, whilst in the secondary circuit were included an adjustable and non-inductive resistance and the coil B, the latter consisting of many turns of fine wire. A small hollow copper cylinder was suspended on a thread in the centre of the two coils, as shown in Fig. 2. If the current was sent through only one of the coils, the cylinder remained at rest; but if currents were sent through both coils, the cylinder immediately started to revolve, twisting the thread on which it was suspended. A reversing switch was inserted in the secondary circuit, and if the current through this circuit was inverted, the cylinder was immediately brought to rest, and started in the opposite direction. Professor Ferraris next substituted a small iron cylinder for the copper one, and found equal results; but when using an iron cylinder sufficiently large to nearly fill the place within the coils, the experiment did not succeed so well. He attributes this to the greater self induction which the presence of iron in a large mass necessarily introduces into both circuits. Another experiment was made with a small iron cylinder, composed of a number of thin discs insulated from each other, and this experiment also succeeded. Foucault currents could not in this case be the cause of rotation, and Professor Ferraris thinks that the rotation is due to hysteresis. A larger apparatus was then constructed, which is indicated in our sketch Fig. 3. In this case the copper cylinder, which was mounted upon a horizontal axis in bearings, had a diameter of 3½in., and was 7in. long, its weight being 11lb. This cylinder was closely surrounded by the primary and secondary coils wound upon wooden bobbins. To make room for the shaft each coil was in halves, the primary consisting of ninety-six turns of seventy-seven mils. wire, both coupled in series, so as to produce the effect of a coil of 192 turns; the secondary consisting of 504 turns of thirty-eight mils. wire, both being coupled in parallel, so as to produce the effect of 504 turns. The resistance of the primary coils was 7·12 and 6·63 ohms respectively, and that of the two secondary coils coupled in parallel was 3·43 ohms. In the secondary circuit was also inserted a rheostat without self induction, and the best results were obtained when the rheostat was set to between 15 and 18 ohms. A Gaulard & Gibbs transformer was used, giving eighty reversals per second. The copper cylinder began to revolve when the primary current was 5 ampères, and with higher currents the velocity could be increased to nine hundred revolutions per minute, and might have been still further increased but for the somewhat imperfect mechanical arrangements, which occasioned considerable vibrations. To the shaft was applied a small friction dynamometer, and the following table gives the work obtained on the brake by a primary current of 9 ampères at different speeds:—

Revolutions per minute....	262	400	546	653	722	770	772	900
Watts obtained on brake...	1·32	2·12	2·65	2·77	2·55	2·40	2·04	0

The maximum energy was obtained at 650 revolutions. Beyond that speed the energy decreased, which is attributed by Professor Ferraris to the imperfect mechanical arrangement of the apparatus, causing a considerable waste of power in vibrations. If it were not for this, the maximum energy would have been obtained at about 1200 revolutions, whilst at 2400 revolutions, which is the speed of the revolving resultant field, no energy at all could be obtained. Professor Ferraris suggests that this apparatus may be used for lecture purposes, and as a motor when the power required is small, and it may also be used as an electricity meter. The torque exerted by the revolving field upon the copper cylinder is proportional to the square of the current, and in order that the total number of revolutions performed in a given time may be an indication of the number of coulombs supplied, it is necessary to introduce some opposing force which varies with the square of the velocity. If this can be done, and if the friction of the journals can be sufficiently reduced, an ordinary counter attached to the axis would indicate the quantity of electricity supplied.

Notes.

DEVELOPMENT OF COSTA RICA.

The British Consul at San José states that a concession of 7000 acres of land has been granted to Marco Soto, ex-President of Honduras, in order that he may form syndicates in the United States and Europe to develop the mines of the country, and establish agricultural and other industries. Special privileges will be granted for a term of ten years, and all machinery and agricultural implements destined for the purposes of these industries will be admitted duty free.

METEOROLOGY.

M. Cruls, the director of the observatory at Rio de Janeiro, is engaged on the compilation of a universal climatological dictionary which promises to be of special value. The publication is under the auspices of the Emperor of Brazil, who has recently written to the President of the Academy of Science in Paris, asking the assistance of the French meteorologists in the undertaking. His Imperial Majesty hopes that the meteorological observatories in France will furnish the editor with details of the work which they are conducting, in order that the volume may be complete in the French methods of investigation.

MINES IN ECUADOR.

The British Consul at Guayaquil reports that the works on the Zarama gold mines continue. New machinery has been put up by the Quebrada Mining Company, which is to commence milling shortly. The Compañia Esplorada de Minas has sent its representative to Europe to make arrangements to raise capital for working about eighteen mines. A new English company has undertaken the exploration of another group of mines in Zarama, and has sent out an engineer and materials for the purpose. The Consul states that so far no decisive results have been obtained sufficient to warrant an opinion being given as to the ultimate success of these new enterprises.

STEAMERS FOR BRAZIL.

The British Consul at Santos states that a native steamship company is in course of formation at that port, and which promises to have commercial success. The scheme has been set on foot by Baron de Jacequay, who intends shortly to proceed to Europe to superintend the building of the steamers, and British shipbuilders should consequently be on the alert to obtain the orders.

PHOSPHATES IN SOUTH CAROLINA.

The British Consul at Charleston states, that whereas in 1867 the quantity of phosphate rock mined in Charleston County was only 6 tons, it amounted last year to 285,000 tons. This industry has materially improved the trade of the port of Charleston, and valuable works have been established on the Ashley and Cooper rivers. The prices ruling for some time past have, however, been unremunerative. The total production in South Carolina in 1887 amounted to 432,757 tons.

COAL IN ALGERIA.

The imports of coal and patent fuel into Algeria amounted to 150,767 tons in 1885, to 115,778 tons in 1886, and to 132,392 tons in 1887. Consul-General Playfair, of Algiers, states that some time ago great pressure was brought to bear upon the railway companies to induce them to use patent fuel of French manufacture. The result of this was that in 1886 the quantity imported from England decreased. After a short trial, however, the railways again purchased their supplies from England, as the French fuel cost 20 per cent. more. The Consul-General says that the consumption of English patent fuel in Algeria amounts to over 20,000 tons per annum; he also states that the consumption of coal in Algiers is likely to increase, as that port is becoming an important coaling station for vessels engaged in the Eastern trades.

COTTON IN RUSSIA.

About 360,000,000lb. weight of cotton are annually imported into Russia, being mainly derived from America and Egypt. The territory acquired in Central Asia by Russia is said to be well suited for the cultivation of cotton, and some Asiatic cotton from Khiva and Bokhara has already been sold on the Russian market. The prospect from the new plantations on the Murghab is very promising, and experiments have been made there by General Paucker and M. Poklevsky Kozell. The latter believes that after the restoration of the Sultan Bekdyke, this tract alone will be sufficient to supply the whole of the Russian Empire. The preliminary essential to these operations is the completion of the irrigation works now in hand, and as these will occupy the next two years it is uncertain, until they are achieved, whether cotton or some other crop will be the most remunerative.

ANCIENT MATERIALS FOR PAPER MAKING.

Dr. Julius Wresner, from a microscopical examination of the paper from El-Faijûne, preserved in the Austrian museum at Vienna, in the collection known as "Papyrus Erzherzog Rainer," has conclusively proved that linen rags were used in the manufacture of paper as early as the eighth and ninth centuries. The fibre is chiefly linen, but there are also traces of cotton, hemp, and animal fibres present. The manufacture of paper out of rags is, therefore, an Eastern and not a German or an Italian invention, as has hitherto been supposed. Out of five hundred Oriental and Eastern specimens, not a single one was a raw cotton paper. All those that were examined had likewise been "clayed" like modern papers. The material used for this purpose was starch paste, manufactured from wheat, and in some cases from buckwheat. Animal substances do not appear to have been employed for "claying" before the fourteenth or fifteenth century.

IODIDE OF MERCURY IN TANNING.

The addition of a small quantity of iodide of mercury to skins is found to effectually prevent fermentation setting in, and at the same time to produce no injurious effects in the subsequent tanning operations. It is said that the mercury salt acts as a preservative of the constituents of the tannin liquors, and that leather produced from skins that have been previously treated in this manner is superior to that tanned in the ordinary way. Messrs. Collin & Benoist, the French chemists, who have experimented with this anti-ferment, state that it completely prevents the liquefaction of the gelatine which takes place in putrefying hides, and thus saves them from this loss. A saving is also effected by its use in the prevention of the decomposition of the tannin in the tanning liquid, which is usually hastened by the introduction of the hides when in a state of decomposition. The amount of iodide of mercury required is so small that there is no possible danger from poisoning, either to the workmen or to those subsequently using the leather, in its use.

6641. Manier, A. F. A. ..... Utilising tidal power.
6644. Roberts, H. ..... Manufacture of wire rods.
6646. Dawson, J. B. ..... Two wheeled vehicles.
6647. Knowles, J. ..... Picking motions for power looms.
6648. Gregson, W. ..... Warping or beaming machines.
6649. Heywood, C. ..... Grinding of the flats for carding engines.
6653. Hateley, T. ..... Tapping holes in metal.
6656. Platt, J. E. ..... Securing the cards in carding engines.
6660. Siviter, J. ..... Axle boxes.
6668. Beaven & Co. ..... Machine mouldings.
6670. McKenzie, S., & others.. Anchoring boats in deep seas.
6674. Addis, J. B. ..... Bosses for forging.
6677. Hewitt, J. ..... Manufacture of lace.
6679. Brasier, E. ..... Decorticating fibrous materials.
6683. Cleminson, J. J. D..... Submarine vessels and torpedoes.
6684. Hill, W. ..... Rudder line ends.
6689. Daverio, G. ..... Sifting machines.
6690. Buignet, H. ..... Testing the strength of cements.
6693. Boulton, M. P. W. ..... Engines worked by elastic fluid with use of combustion at high pressure.
6698. Forster & Dawson..... Boilers.

5th May, 1888.

6700. Donovan, J. W. ..... Reversing valves.
6704. Bailey, W. H. ..... Wool combing machines.
6705. Williams, W. J. ..... Fire and damp proof cylinders for explosives.
6708. Louks, A. ..... Gas engines.
6711. Seidenberg, B. ..... Cleaning breech loading rifles.
6718. Johnson, J. Y. ..... Looms for weaving ribands (*Moraes*).
6736. Howes, J. ..... Float and valve mechanism for tanks.
6739. Vaughan, G. E. ..... Steering apparatus for twin screw ships (*Trott*).
6742. Wise, W. L. ..... Steam engines (*Maschinenfabrik Oerlikon*).
6744. Edwards, E. ..... Iron floors (*Hahn*).
6750. Turner, G. H. ..... Drilling and tapping holes in pipes.
6754. Key & Gales ..... Tube stopper and scraper for steam boilers.

7th May, 1888.

6756. Nelson & Nelson ..... Dyeing and sizing yarns.
6763. Walker, W. ..... Lace machines.
6766. Lang & Dannfield ... Rotary engines.
6774. Holt & Holt ..... Manufacture of figured cloth.
6788. Walter & Edmeston... Mangles for treating textile fabrics.
6794. Stitt, J. C. ..... Mechanically propelled lifeboats.
6795. Pooley & Pooley..... Weighing machines.
6799. Stevenson & Marshall Motors and apparatus for raising and forcing fluids.
6808. Stuart, G. ..... Machine for filling the feeders of Gatling guns.

8th May, 1888.

6816. Newall, G. W. ..... Pistons and valves.
6619. Nash & Lacassagne..... Couplings for railway carriages.
6821. Berry, J. H. ..... Valve motion for steam pumps.
6825. Fairweather, W. ..... Apportioning furnace draft for batteries of steam boilers (*The Babcock & Wilcox Co.*).
6830. Shackleton, R. ..... Injectors.
6832. Hopwood, J. ..... Shaft bearings.
6835. Green, E. C. ..... Breech loading small arms.
6847. Farmer, J. S. ..... Washing textile fabrics.
6852. Balls & Hudson ..... Governors for steam engines.
6854. Snedeker, E. W. ..... Sawing machines.
6856. Backeljau, F., & others Pneumatic elevator.
6863. Hutinel, H. ..... A novel apparatus applied to steam boilers.
6864. Goodfellow, J. T. ..... Metallic platforms for railway cars.
6870. Servettaz, J. ..... Working points and signals of railways.
6879. Chamberlain, E. G. ... Compound railway rail.
6884. Barker, W. B. ..... Air valve, applicable to mechanism for signalling.
6885. Barker, W. B. ..... Sound signalling apparatus.

9th May, 1888.

6886. Bookwalter, J. W..... Iron and steel (*Robert*).
6890. Fasham & Pyle ..... Using the action of the tides.
6894. Brampton & Brampton Driving chains.
6895. Mills, E. C. ..... Self acting stop motions applied to speed regulators for steam engines.
6897. Hutchinson & Younghusband ..... Securing connecting rod straps to connecting rod ends.
6898. Pearson, H. ..... Pickers of looms.
6904. Pilley & Darnbrough. Apparatus for making flake yarn.
6911. Poole & Poole..... Mules.
6912. Wrigley, E. W., & ors. Doubling and twisting machinery
6913. Penn & Deeley ..... Ejecting mechanism of drop-down small arms.
6914. Mudgemarchant and Abbott ..... Application of steam to engine power.
6918. Hall & Verity ..... Anchors.
6919. Atkinson, E. S. ..... Discharging projectiles from guns.
6922. Johnston, J. ..... Production of moulded castings (*The Société du Familisteri de Guise Vve Godin et Cie*).
6930. Vaughan, G. E. ..... Twin screw ships (*Trott*).
6936. Blachon & Mimard ... Sporting guns.
6942. Offen, F. ..... Coupling.
6951-2. Bookwalter, J. W.... Iron and steel.

10th May, 1888.

6959. White, H., & others..... Corrugated girder fire bar for furnaces.
6962. Cryer, J. M. ..... Drag motions for flyer doubling and spinning frames.
6969. Kiddier, J. W., & others Straight bar knitting machines.
6970. Huck, G. ..... Tension bar for looms.
6971. Annandale, J. H. ..... Boiler furnaces.
6976. Farini, G. A. ..... Magazine attachment to the Martini rifle.
6980. Lazenby, G. ..... Muffle kilns for bending and firing stained glass.
6981. Cocker & Cocker ..... Mules.
6984. Henderson, A. C. ..... Steam boilers (*Desgoffe and De Georges*).
6986. Lowth, T. ..... Centrifugal apparatus for extracting honey from honey comb.
6987. Ellis, O. J. ..... Steam generators.
6989. Wade, J. ..... Looms for weaving pile fabrics.
6990. Thompson, W. P. ..... Two wheeled vehicles (*Vandenplas*).
6994. Romanel, R. C., & ors.. Magazine repeating fire arms.
6998. Whitehead, R. ..... Valve for torpedo engines.
7000. Richmond & Whiting.. Printing presses.
7009. Haddan, R. ..... Pumps (*Mosser & Chiari*).
7011. Wells & Hitton..... Hot air motor.
7012. Wells, C. ..... Apparatus for recording the degree of accuracy in aiming with ordnance guns.
7013. Wells & Paynter ..... New method of using steam as a motive power.
7014. Goodwin & Goodwin... Travellers for carrying suspended loads.
7015. Casson, R. S. ..... Manufacture of metallic tubes.

ELECTRICITY.

4th May, 1888.

6657. Williams, B. D. ..... Secondary batteries.
6680. Vaughan, G. E. ..... Electric railways (*Trott*).

5th May, 1888.

6740. Armstrong & Serrailler ..... Portable electric lamp.
6751. O'Leary, C. M. ..... Automatic alarm bells.

7th May, 1888.

6772. Calliphronas, T. ..... Electrical measuring apparatus.

8th May, 1888.

6828. Tolehard, F. J. ..... Automatic telautograph.
6834. Chattock, A. P. ..... Measurement of the co-efficients of electro-magnetic induction.
6836. Ayrton, W. E., & others Electro-dynamic relay for constant or varying currents.
6876. Aron, H. ..... Measuring electric currents.

9th May, 1888.

6889. Firth & Crabtree..... Dynamos and motors.
6893. Walker, E. C. ..... Electro-magnetic and magneto-electric generators.
6907. Immisch, M. ..... Storage batteries.
6909. Houghton, E. J. ..... Dynamo machines.
6910. Houghton, E. J. ..... Electric lighting.
6927. Ward, M. R. ..... Electrically propelled vehicles.
6928. Andersen & Tafe ..... Electric switches.
6953. Southern, W. ..... Electric gas lighters.

10th May, 1888.

6961. Nussbaum, G. A. ..... Electric batteries.
6985. Immisch, M. ..... Switch for electrical tram cars.
6988. Ward, M. R. ..... Supplying electrically worked vehicles with fresh sets of accumulators.

CHEMISTRY.

4th May, 1888.

6694-5-6. Hake & Heenan ... Ammonium nitrate.

5th May, 1888.

6725. Card, W. L. ..... Eliminating metals from their matrices.
6743. Leigh, H. H. ..... Colouring matters (*Williams*).

7th May, 1888.

6778. Kiel & Stoltenhoff... Manufacture of starch.
6812. Rose, T. K. ..... Recovery and regeneration of bromine, chlorine, and other chemicals employed in the extraction of gold.

8th May, 1888.

6869. Johnson, J. Y. ..... Purifying alcohol and obtaining aldehydes and acetones (*La Société Française de Alcools purs of Paris*).

9th May, 1888.

6899. Limpach, L. ..... Separation of isometric xylidines.
6949. Mitchell & Hagemann Purification of oils and fats (*Von Schmidt*).
6956. Greenway, A. G. ..... Manufacture of zinc.

10th May, 1888.

6972. Hannay, J. B. ..... White pigment of lead.

MISCELLANEOUS.

1851A. Johnson, J. Y. ..... A sound conveying tube (*The Volta Graphophone Company*). (This Application having been originally included in No. 1851, dated 7th February, 1888, takes, under Patents Rule 23, that date.)

4th May, 1888.

6639. Ambler, W., & others... Glass bottles.
6643. Pickup, J., & others..... Shuttles.
6652. Tunks, D. ..... Watches.
6654. King, F. W. ..... Brush with removable cover.
6663. Mowll, C. H. ..... Artificial fuel.
6667. Ingrey, C. ..... Apparatus for producing sonorous and flashing signals.
6669-71. Boult, A. J. ..... Extracting wool oil (*Korschelt*).
6675. Bill & Taylor..... Silk warp threads.
6676. Holdsworth, G. ..... Securing top rollers upon their spindles.
6681. Clarke, A. B. ..... Automatic washing apparatus.
6686. Williams, S. de la G... Lock bolts and nuts.

5th May, 1888.

6701. Battye, A. ..... Oil lamp.
6712. Craven & Craven ..... Pressing bricks.
6714. Ingram, G. ..... Extinguishing lamps.
6716. Garnett & Sawley..... Screws of gill boxes
6722. Bergh, W. ..... Milking machines.
6724. Brand, C. ..... Manufacture of paving blocks.
6727. Waddington, J. ..... Railway brake pipe coupling (*Massey*).
6728. Sturm & Schrader ... Wiring bottles.
6733. Haggenmacher, C..... Middlings purifiers.
6734. Imray, O. ..... Drying organic substances (*Richter*).
6745. Sutcliffe, T. ..... Stoppers for bottles.
6746. Lighbody, W. ..... Oil lamps.
6748. Steinbrenner, D. C. E. Anemometers.
6753. Atkins & Atkins ... .. Filtering apparatus.

7th May, 1888.

6757. Graetz & Kiesow ..... Lamp burners.
6759. Lucas, P. ..... Step ladders.
6760. Bell, J. H. ..... Preventing accidents and facilitating traffic in thoroughfares.
6762. Kay, T. ..... Tyres.
6764. Tucker, E. ..... Evaporating and concentrating liquids.
6770. Brown, J. ..... Handle for screw drivers.
6771. Cadman, C. W. ..... Packing for stuffing boxes.
6773. Calliphronas, T. ..... Clocks.
6776. Wagstaffe, Baron W. de..... Sight for fire arms.
6780. Williamson, J. C. ..... Cleansing the bottoms of navigable vessels.
6781. Michaud, J. ..... Damping apparatus for lithographic and zincographic presses.
6782. Battye, A. ..... Oil lamps.
6785. Johnson, S. A. ..... Lamps.
6790. Buck, T. ..... Cutting and loading bricks.
6807. Stuart, P. ..... Pavements.
6809. Edwards, E. ..... Sickles and scythes (*Von Löbbecke*).

8th May, 1888.

6813. Tennant, W. J. ..... Door checks.
6817. Turner, J. S. ..... Manufacture of boots.
6818. Jagger, E. ..... Stoves for heating soldering irons.
6826. Denniston, P. ..... Chimney cowls.
6827. Storrar, J. M. ..... Manufacture of candles.
6829. McLelland, T. G. ..... Lifting and loading earth.
6851. Hagemann, O. C. ..... Extracting moisture.
6853. Payne & Burstow ..... Burners for oil lamps.
6855. Crastin & de Pass..... Lamps.
6857. Westbrook, F. A. ..... Fire escapes.
6859. Utzon, M. L. ..... Mill stones.
6862. Defries & Feeny ..... Feeding oil for lighting and heating.
6865. Jones, E. ..... Thermometers.
6866. Blackstone, E. C. ..... Horse rakes.
6872. Thompson, W. P. ..... Rustless coating on iron and steel surfaces (*Wells*).
6874. Delf, F. D. ..... Retort stands.
6875. Favier, A. ..... Cartridges and detonators.
6877. Thompson, W. P. ..... Metallic wheels' rims (*The Warwick Cycle Manufacturing Company*).
6881. Macneill, T. ..... Uniform supply of oil in lamps and lubricators.

9th May, 1888.

6887. Holme, J. W. ..... Weavers' loom shuttle tongues.
6892. Crisp, W. ..... Rim and mortise lock.
6896. Pullon, J. T. ..... Drying and mixing cement.
6900. Spencer, G. S. ..... Bottles.
6905. Day, J. M. ..... Glass bottles.
6920. McIntosh-Valon and Brin's Oxygen Co.... Purification of coal gas.

Digitized by Google

6923. Methven, J. ..... Lamps.
6925. Cousins, C. ..... Screens for cleaning corn.
6929. Challenger, G., & ors. Machines for striking cycloidal curves.
6931. Gibson, W. A. ..... Operating the valves of hydraulic elevators.
6932. Thomson, J. ..... Meters for water.
6933. Davies, E. A. ..... Manhole covers for metal tanks.
6935. Harmer, H. A. ..... Tightening wires.
6938. Neal, E. ..... Wedge joint for steel or iron rails.
6944. Lake, H. H. ..... Manufacture of blocks for building purposes (*Van Berkel*).
6947. Simon, H. ..... Mounting and driving of sieves.
6948. Macneill, T. ..... Oil lamps.

10th May, 1888.

6965. Brindley, J. ..... Gulley traps.
6973. Fallows, F. ..... Shuttle tongue for cops used in weaving calico.
6974. Hunt, J. J. ..... Stoppering bottles.
6975. Waser & Davonport ... Lamps.
6983. Armstrong & Armstrong ..... Locks.
7002. Mills, B. J. B. ..... Brakes (*Guetton-Danyon & Des Georyes*).
7003. Otway, G. ..... Cutting bricks.
7007. Royer, C. L. ..... Treatment of hides for belting.
7010. Matton, J. ..... Automatically extinguishing lamps.

COMPLETE SPECIFICATIONS ACCEPTED.

Persons interested in opposing the grant of the following patents may give notice of opposition at any time within two months after the dates given.

ENGINEERING.

12th May, 1888.

1524. Mantle, A. W. ..... Thrashing machines.
6485. Bureau & Hendlé ..... Steam motors.
7033. Vosper, C. W. ..... Sewing machines.
7346. Smith, H. ..... Breech loading small arms.
7628. Walker, H. ..... Boiler and smelting furnaces.
7708. Foster, N. R. ..... Kilns and drying floors for the manufacture of cements and limes.
7729. Benton, C. H. ..... High speed steam engines.
7844. Michaelis, E., & others. Gig mills.
8128. Fabre, A. J. ..... Shuttle pickers for looms.
8161. Horrocks & Horrocks Pickers employed in looms.
8172. Ambler & Blackburn.. Steam boilers.
8331. Spencer, G. ..... Steam pressure reducing valves.
8417. Lister, H., & others ... Pickers for looms.
8450. Low, R. ..... Dovetailing machine.
8518. Garrett & Webster... Self feeding punching and eyeletting machine.
9447. Bansen, W. ..... Manufacture of hoop iron.
9531. Webb, E. ..... Apparatus for printing floor cloths.
9555. Quick, G. ..... Ordnance.
9581. Clark, E. S. ..... Manufacture of nails.
9603. Reynolds, O. ..... Friction clutches.
9615. Johnys, W. E. ..... Temples employed in looms.
9661. Ness, A. ..... Lubricating journals.
9664. Pearson, J. J. ..... Apparatus for drying sand (*McDonald*).
9671. Trelease, E. H. ..... Pneumatic brakes for railways.
9687. Christie, R. C., & others Gun carriages (*Canet*).
9860. Molyneux-Seel, E. H... Brake appliances for road vehicles
9928. Lang, J. ..... Slide valves.
9932. Finch, T. F. N. ..... Axles and axle boxes.
9969. Morton, R. G. ..... Crushing and grinding grain.
9989. Holden, I. ..... Apparatus for drawing of fibres in combing machinery.
10070. Kay, T. B. ..... Carding engines.
10151. Orton, R. H. ..... Combined brakes, buffers, and draw gear.
10230. Brayshaw, G. ..... Brake for the cylinders of lithographic and letterpress printing machines.
10398. Lloyd, F. H. ..... Crossings of railways.
10672. Barlow, H. B. ..... Manufacture of woven belting.
11187. Holroyd & Thompson.. Pressing woven fabrics.
11395. Clifford, I. E. ..... Shaft for screw propellers.
13436. Lea, H. ..... Gas engines.
15077. Chambers & Liddell... Lifeboats.
16420. Heenan, R. H. ..... Spherical engines.
16710. Edison, T. A. ..... Prime motors.
17561. Schneider & Werth ... Converting reciprocating into rotary motion.
192. Berry, H. ..... Applying varying degrees of pressure to hydraulic cylinders.
385. Bolton, J. ..... Sewing machines.
579. Walkden, S. ..... Eccentric.
3154. Binns, L. ..... Spinning and twisting machines.
3339. Evans & Hall ..... Generating steam.
3751. Imray, O. ..... Fish plates for railway rails (*Lee*).
4173. Swartzbaugh, J. H., and others ..... Spark arrester.
4431. Henderson, F. J. ..... Ball valves.
4696. Schenck, U. H. W. ..... Belt holders and shifters.
4925. Smith & Smith ..... Jacquard machines.
4973. Dowling, P. ..... Presses for hay, straw, wool, &c.
5213. Cox, R. ..... Machine for polishing glass, marble, stone, &c.
5240. Hague, W. ..... Protecting boiler tubes.
5244. Mauser, P. ..... Breech loading fire arms.
5325. Lake, H. H. ..... Manufacture of cut nails (*McKay*)
5326. Lake, H. H. ..... Washing machines (*Schumpe and Hammelrath*).
5335. Binns, L. ..... Spinning and twisting machines.
5338. Abel, C. D. ..... Treating textile fabrics with steam (*Koethe*).
5402. Mills, B. J. B. ..... Ships' propellers (*Bidauld*).

ELECTRICITY.

12th May, 1888.

6400. Schiller & Meyer..... Electromagnetic apparatus for the automatic lighting and extinguishing of gas lamps.
7189. Akester, W. H. ..... Secondary batteries.
8495. Clark, A. M. ..... Electric lamps (*Bertou*).
9598. Timmis, I. A. ..... Electrical apparatus for working railway signals.
2369. Orme, J. ..... Electrical signalling between driver and guard.
3246. Walker, F. ..... Electric lamp.
3303. Leigh, H. H. ..... Registering the consumption of electric energy (*Clerc*).

CHEMISTRY.

12th May, 1888.

6417. Marx, J. ..... Alkalies.
9227. Wigg, C. ..... Bicarbonate of soda.
9706. Clark & The Panther Lead Company..... Condensing and separating lead fume.
17625. Mitchell, C. ..... Gold washing machines.

MISCELLANEOUS.

12th May, 1888.

1816. Boult, A. J. ..... Bleaching vegetable tissues.
6555. Blackburn & Mori ... Lamps.
7046. Thorne & Burr ..... Lenses and reflectors for lamps.
8176. Eastwood, G. ..... Manufacture of moulds for stereotype plates.
8266. Cliff & Peto ..... Building block.
8306. Boult, A. J. ..... Velocipedes (*Renz*).
8949. Palmer, E. J. ..... Lamps.
9148. Cormack, J. H. ..... Doors for flues.
9199. Boult, A. J. ..... Cooling, heating, or purifying liquids, gases, and vapours (*Fischer*).
9280. Spencer, G. S. ..... Bottle stoppering.
9617. Harrison, J. ..... Metallic grit for cutting stone.
9711. Crastin, C. ..... Lamps.
9957. Trassl & Lindner ..... Manufacture of thin plates of glass.
11274. Rigby, J. S. ..... Whiting and cement.
13699. Singer & Judell..... Cleansing wool.
17130. Shelley, T. R. ..... Glazing roofs.
17853. Upsdale, J. ..... Manufacture of gloves.
17928. Chapman, G. J. ..... Cycles.
738. Smart, H. R. ..... Hydrodynamic ventilating apparatus.
2533. Hovde, A. G. ..... Lamp extinguisher.
3673. Rowatt, J. M. ..... Lamp burners.
3674. Lighbody, W. ..... Lamp burners.
4289. Dunn, B. S. ..... Gas and air comminglers.
4771. Hill, E. C. H. ..... Bottle.
4831. Nickels, B. ..... Filtering funnels.
4953. Westphal, C. ..... Production of water gas.
5001. Fahie, A. ..... Apparatus for counting boards (*Nielsen*).
5089. Campbell & Campbell Masts of ships.
5090. Heimsoeth, B. ..... Locks.
5203. Pontois, L. J. le..... Transmitting sounds to a distance by means of light.
5305. Petri & Hausmann..... Syphons.
5337. Abel, C. D. ..... Supplying cooled air to rooms (*Koethe*).

PATENTS VOID THROUGH NON-PAYMENT OF RENEWAL FEES.

(*To the 5th February, 1888, inclusive*).

Year 1884.

ABSTRACTS OF BRITISH PATENT SPECIFICATIONS.

Compiled from the Published Specifications by W. E. Heys, 70, *Market-street, Manchester.*

ENGINEERING.

Fuel Economisers.—*Sir E. Green, Wakefield*.—The object of this invention is to cause a rapid and more positive action of the reversing gear of the scrapers of fuel economisers, by arranging the upper part of the trip lever with a race, in which a rolling body has a free action to either end as the trip lever is lifted to a position just beyond the vertical, the rolling body suddenly moving to the outer end of the race to throw the

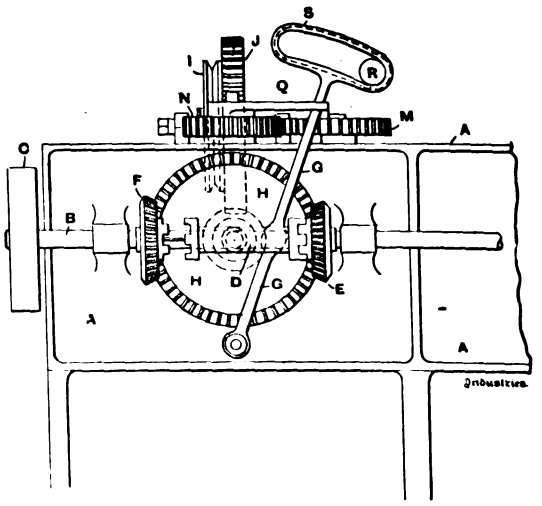

Fig. 1.

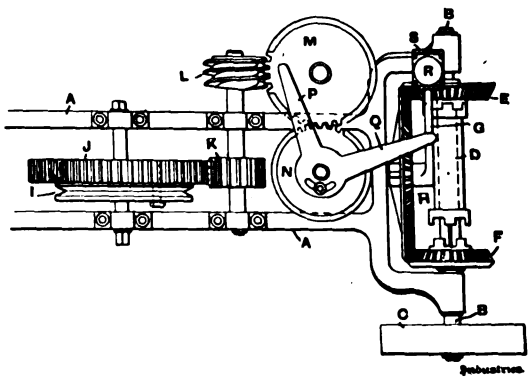
reversing gear over and so reverse the travel of the scrapers. In the figures, A is the upper frame carrying the shaft B, which is driven by a belt passing round the wheel C. A double clutch tube D is free to slide on the shaft B, and can engage with either of the clutch wheels E F when shifted over by the trip lever G. The clutch wheels E F both gear with a wheel H. The shaft on which the wheel H is mounted also carries a wheel gearing with the toothed wheel J. The scraper chain pulley is fastened to the wheel J by means of a bolt. The wheel J operates a pinion K which is fixed on the same shaft as the worm L, and the combination worm and spur wheel M communicates the motion to the wheel N, whose axis carries the



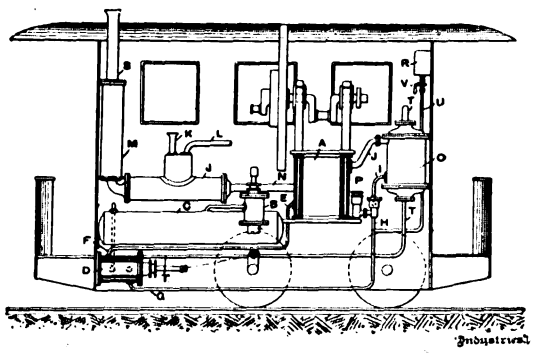


Fig. 2.

two arms P Q. These arms extend within reach of the trip lever G, and alternately move the lever back and forward; when the lever arrives at a position just beyond the vertical, the ball R suddenly moves to the other end of the race S, and causes the lever to move rapidly and to shift the clutch from one gear wheel to the other. These motions are arranged to take place when the scrapers have arrived at the end of their travel. The inventor claims: Providing the upper part of the trip lever of the reversing gear of a fuel economiser with a ball or other rolling or sliding body, which has a free action to either end for carrying the trip lever suddenly over, and for reversing the travel of the scrapers.—No. 7623. May 25th, 1887. 8*d*.

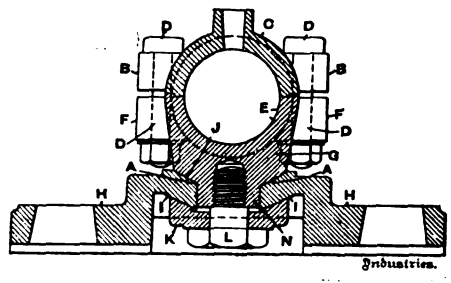
Shipping Coal.—*P. G. B. Westmacott, Newcastle-on-Tyne.*—The apparatus here described is designed for the purpose of transferring coal and other materials from railway waggons to the hold of a ship, with as little breakage as possible. A frame is pivoted at one end, and when horizontal it receives the shipping box on its pivoted side and the railway truck at the other end; a hopper is interposed between the box and the truck, and the box is carried upon a secondary frame which is pivoted to the main shipping frame. When a full truck has been run on to the frame its end flap is unfastened; the frame, with the hopper box and truck, is then raised and turned round its pivot, and the coal gradually runs down from the truck through the hopper into the box. After the truck has been emptied, the main frame is lowered to its former position, while the tilting of the secondary frame is continued until the box is in a vertical position, when it can be removed by a crane and emptied. These movements of the frames are generated by hydraulic power. For raising the main frame two cylinders are employed, a large one for giving the first part of the lift, and a smaller one for the latter part of the lift, which requires less power, on account of most of the coal having flowed towards the pivoted end. The inventor makes seven claims.—No. 8447. June 10th, 1887. 11*d*.

Digitized by Google

COMBINED GAS AND COMPRESSED AIR ENGINES.—*E. Stevens, Brussels.*—These improvements are applicable to locomotives which are used on tramways. The gas engine is combined with the compressed air engine in such a way that the cylinders of each engine are covered with water jackets communicating with one another; the water is caused to circulate between them by means of a pump, for the purpose of cooling the gas cylinder and heating the air cylinder. The general arrangement is shown in the accompanying figure. The gas motor A serves two purposes, viz., to actuate the air compressing pump B, and to drive the pump P, which is employed to set the water in circulation. The pump B compresses the air into the receptacle C, whence the air passes through the air motor D and into the receptacle O. The gaseous fuel is composed of compressed air and the vapour of naphtha, petroleum, or other hydrocarbons. The exhaust gases from the gas motor A pass through a series of tubes inside the vessel J, in which is contained the hydrocarbon; the air enters at K, and the gaseous mixture leaves at L for the induction valve of the motor A. The products of combustion, after having evaporated the fuel, pass through the vessel M and pipe S into the atmosphere, and an asbestos lining is fixed inside the vessel M, for the purpose of deadening the puff of the engine. The air motor D is provided with a jacket in the same manner

as the gas motor A, and the tube E F connects the interior of the two jackets. The jacket of the motor D is connected by means of the tubes G H with the pump P, whose pressure tube I is led to the cooling apparatus O. The water of the two jackets is sucked into the apparatus O by the cooling action of the exhaust air from D. The air leaving the cylinder of the air motor enters through the tube T^1 into the interior of O, and escapes through the tube T^2, and the water sucked by the pump P through the pipe G H from the cylinder jacket enters through the pipe I into the space in O surrounding the pipes through which the cold air passes, and flows off through the pipe J to the jacket of the gas motor. To compensate for the gradual loss of cooling water, and to supplement the cooling effect of the vessel O, a small cold water reservoir R is arranged, from which the water can be let direct into the pipe G H through the pipe U. Three claims are made for the combination of the double walled cylinders D A with the chamber O and the pump P for the purpose of keeping up a constant circulation of the cooling water, for the carburetter, and for the silent exhaust apparatus M, as described.—No. 4843. March 31st, 1887. 8*d.*

GAS ENGINE.—*C. Davy, Sheffield.*—The object of this invention is to obtain a ratio of expansion of the ignited gases greater than that of their previous compression, and to effect the complete expulsion of the waste gases from the cylinder. These results are accomplished by causing the piston to make strokes of unequal length and at different positions in the cylinder, the length of the inhaling and working strokes being normal, and the compression stroke less and the exhaust stroke greater than the normal. Two cylinders are employed, and their pistons are coupled to the same crank; the four cycle principle on which the engine works is so timed as to make the first and third and second and fourth strokes take place at the same time in the different cylinders. The connecting rods are coupled to the crank through the medium of an equal armed tumbler or elbow lever, whereby at certain points of the revolution the positions of the pistons relatively to each other and to their cylinders are changed so as to cause them to make strokes of different lengths at different stages of the cycle. Four claims are made for this method, and for its applications.—No. 7677. May 26th, 1887. 8*d.*



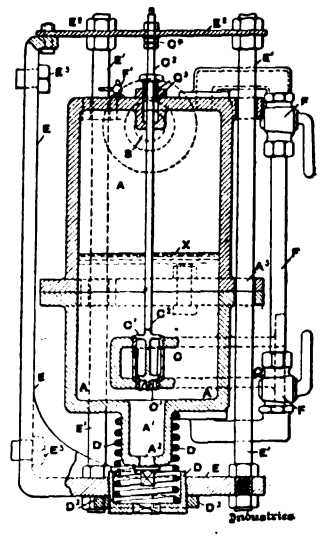
CHAFF CUTTER.—*J. Keeble & C. E. Mumford, Bury St. Edmunds.*—This chaff cutter is intended to be attached to a thrashing machine immediately behind the shakers, and an arrangement is made for throwing it in and out of gear as required. The cutter consists of a set of knives secured to a spindle, upon which they can be adjusted by means of screws, springs, or collars. The spindle is carried on two bearings which are also made adjustable to make up for wear. To a finger bar, consisting of an iron rod or tube, are attached a series of clips of iron corresponding in number to the knives; these clips surround the cutting edges of the knives, and come up close against the flat edges. A clearer bar is fastened to the back of the knives, in order to remove the chaff as it is cut; it consists of a rod or tube fitted with spikes, which can be adjusted by a screw to suit the position of the knives. At the top of the knives is a slotted bar which carries some material for sharpening the knives as they revolve, and a set of rakes driven by a crank serve to bring the straw up to the knives. Three claims are made.—No. 5217. April 9th, 1887. 8*d.*

PAPER PULP STRAINERS.—*R. Wood, Leith, Midlothian.*—In the machines to which this invention is applicable, a pulsating motion is imparted to the pulp, so as to draw it through strainer plates, which are fixed in a horizontal position in a shallow vat. In improving these parts, the inventor forms one or more openings in the bottom of the vat. In the ordinary pulp straining apparatus there are preferably two openings about 2ft. long by 18in. broad. On the edges of each opening is fixed a band of rubber of semi-circular section, with the convexity outwards, so as to act like a spring. The lower lip of the band is fixed to the edge of the bottom opening by means of an inner flat ring and screw bolts, and the upper lip is similarly fixed to a plate of the same shape as but larger than the bottom opening; this plate is connected by a rod to a crank on the rotating shaft below. The inventor claims the method of imparting a pulsating action to the pulp by plates moved by rotating cranks, and placed over openings in the bottom of the box, the plates being connected to the bottom of the box by rubber bands, as described.—No. 8591. June 15th, 1887. 8*d.*

MULES.—*W. Taylor, Oldham.*—The object of this invention is to prevent the snarls ordinarily occurring in yarn which is spun on the spindles near the headstock. When the carriage is being drawn in, the part of the carriage near the headstock springs and bends, and, in consequence, the yarn on this part of the mule becomes slack, and the cops are not wound tightly. This defect is obviated in the present invention by giving the spindles near the headstock a slightly greater speed than the rest. One or more lengths of the tin rollers on each side of the headstock are made of a slightly greater diameter than the others, or the wharves of the same spindles may be reduced in diameter; the desired result will be obtained by either of these two methods. Three claims are made, for giving these spindles a greater speed, and for the two ways of effecting it.—No. 9136. June 28th, 1887. 8*d.*

PRINTING MACHINES.—*A. H. Marinoni & J. Michaud, Paris.*—The machine is arranged to print on both sides, or on one side only with a single feed, or on one side only with a double feed; the special arrangements for printing in one or other of these methods have been described in Patent No. 11393 of 1885. In the machine for printing on one side only with a double feed, the cam carrier described in that patent is modified according to this invention; its two ends carry the cams which act on the rollers of the grippers of the delivery cylinders. These cylinders carry toothed wheels which gear with the wheels on the printing cylinders, and are of such a diameter that they make exactly a given number of revolutions while the printing cylinders revolve twice; the meeting of their grippers with those of the printing cylinders thus takes place every time the latter have a sheet to deliver to them. The sheets taken by the grippers of the delivery cylinders are either conveyed to the delivery by a set of tapes to be directed to the mechanical receiver, or are delivered by tapes above the receiving table and placed upon the table by hand. In order to enable the top of the type table to be easily uncovered, the rollers round which the tapes pass may be fixed to the feed table, so that in raising the latter the set of tapes will be raised at the same time. The tapes, which hold the sheets when they have been released by the grippers, may be replaced by balls of india-rubber. The inventors make three claims.—No. 8485. June 13th, 1887. 8*d.*

PEDESTALS FOR ROTATING SHAFTS.—*W. Hargreaves & R. Harwood, Bolton.*—The object of this invention is to allow for the self adjustment of pedestals in order to reduce the strain and friction due to errors of level or alignment. The body E of the pedestal is provided with a vertical stem G; the under side of the stem



takes the form of a spherical surface, whose centre coincides with that of the bearing. The upper side of the base plate H is constructed with a concave surface A, which receives the convex end of the stem G. The under side of the base plate H is formed with a spherical surface I struck with a radius from the centre of the pedestal. This surface bears upon the disc K, which is secured to the pedestal and to the base plate. The base plate has a slot which admits the projection N; the slot allows the adjustable part of the pedestal to swivel longitudinally, but prevents it tilting laterally. The snugs F are cast on the body E of the pedestal, and receive the bolts D by which the cap C is secured. The base plate H can be provided with an oil dish if desired. This arrangement of the bearing and its supports allows of the self adjustment of the bearing. Two claims are made for this bearing and for another modification.—No. 6329. April 30th, 1887. 8*d.*

EXCAVATORS.—*J. H. Morgan, Liverpool.*—This invention relates to the grabs which are used in dredging and excavating. The jaws of the grab are pivoted to the shaft which carries the opening and closing gear, and also to a raising and lowering cross head. The jaws are made of one piece of metal, and their sides are shaped so as to overlap one another when closed. The arms pivoting the jaws to the raising and lowering cross head, and the outline of the lower edges of the jaws, are so regulated that the distance between the surface on which the opened jaws rest and the cross head decreases as the jaws close. The opening and closing gear consists of snail-shaped cams, which are connected to the cross head and to the raising and lowering chain by suitable flexible agents. For excavating, the grab is made of a number of blades threaded on shafts, to which the raising and lowering arms are pivoted; the blades are bound together by other shafts passing through eyes, and the whole is hinged to the opening and closing shaft by means of stay pieces. Seven claims are made.—No. 8328. June 10th, 1887. 8*d.*

COAL MINING.—*T. C. R. Horsfield & R. Porter, London.*—In cutting and boring the blast holes, the inventors make use of a specially designed hydraulic press, which consists of a metal cylinder, divided longitudinally into two parts. In the larger of these two portions there is a cavity passing through its length; and a series of holes, fitted with rams, are arranged transversely to this cavity, and in communication with it. The ends of the rams touch the other portion of the cylinder, and are provided with hydraulic leathers, in order to secure an air tight joint. On the admission of water to the cavity, the pressure is applied on the ends of the rods, which are consequently forced outwards. Three claims are made for the construction of the hydraulic press, with the cavity and the separate access for the fluid to each hydraulic ram.—No. 14344. October 21st, 1887. 8*d.*

STEAM TRAP.—*A. D. Marshall, Sydney, New South Wales.*—This improved automatic steam trap consists essentially of a receiver, which elastically retains its discharge valve in a tightly closed position, and is allowed a movement to discharge itself when a certain weight of water has accumulated. In the accompanying figure, A is the container or receiver, B is the inlet, and C the outlet; A^1 is a mud well, A^2 a plug, D a supporting spring, C^1 an equilibrium valve, C^2 its spindle, and F^1 the pet cock. The guide rods E^1 are firmly held in the saddle E and by the top plate E^2. The level of the water in the container having been determined, the saddle E is firmly bolted in position, and

the valve spindle is jambed to the plate E^2 by the nuts C^4, and the spring D is adjusted by means of the screwed socket D^1 until the water, which it is desirable should remain in the container, will retain the valve C^1 tight upon its seat. When the water rises above the desired level marked X in the figure, the extra weight will cause a depression of the spring D, and the container A will slide downwards on the rods E, and its seat will fall away from the valve C^1. The water will thus be discharged through the outlet C; when sufficient water has escaped the upward pressure of the spring D will cause the valve to close again. If desired, the equilibrium discharge valve may be constructed in a separate box fastened to the outside of the container; or the discharge may be regulated by means of a cock actuated by levers receiving their motion from the movement of the container. Four claims are made.—No. 12878. September 22nd, 1887. 6*d.*

ELECTRICITY.

ELECTROMOTORS.—*C. Coerper, Cologne, Germany.*—The armature and the field magnets are mounted on the same shaft, the field magnet being rigidly connected, and the armature loose. The two elements are fixed on the circumference of two equal wheels, which are placed side by side on the shaft. The driving wheels of the machine are also mounted upon the same shaft, and by the application of a brake to the loose armature the speed of revolution may be varied while the potential of the current remains the same. This invention is more particularly applicable to tram engines. Four claims are made.—No. 633. January 14th, 1887. 8*d.*

DYNAMOS.—*J. Swinburne, Chelmsford.*—This invention consists of an induction apparatus for studying dynamos, and for developing new types. It is at present almost impossible to calculate the results which will be obtained from a particular arrangement of the parts. According to this invention, a model is made to scale, which consists of the ordinary field magnets and armature. There is no commutator needed, and the terminals of the wire are used instead of brushes. The armature is not rotated, but is held in position in the field so that it can be moved round into any angular position representing a desired lead of the brushes. The induction through any part of the model is then measured by means of a pilot wire and a ballistic galvanometer. The galvanometer is calibrated by means of a pair of coils whose co-efficient of mutual induction is known. To find the "no load" curve of the machine, gradually increasing currents are passed round the fields, and the armature induction is noted by observing the motion of the galvanometer on the reversal of the exciting current. To take "full load" readings, a current is also passed through the armature wire; when both the armature and field circuits are reversed the induction is measured by means of a pilot wire, as the armature circuit alone is no longer convenient for the purpose. The distribution of the induction in the air space at different loads is measured by means of a pilot wire circuit. The change of induction through a section of armature conductor corresponding to one pair of commutator sections is taken by reversing the current in a model section without reversing the armature and field magnets. In the case of the alternating current machines, the "no load" curve is not obtained directly from the total induction through the armature circuit; but as the e.m.f. at any instant depends on the rate of change of the total induction, the curve is readily found. To obtain full data, a pilot wire is used, and the induction is determined at each armature position. As the models are apt to get very hot, the currents are manipulated

Digitized by Google

by a switch, and the heating thus lasts only a short time. The inventor claims: (1) An induction apparatus consisting of a scale model and apparatus for measuring the induction in parts of the model, and (2) dynamos or motors constructed from data obtained from such a scale model.—No. 6219. April 28th, 1887. 6*d*.

Dynamos.—*H. Watt, London.*—One feature of this invention is the employment of a single core of circular form and of large sectional area, which is wound on the longshunt system. This core is placed at right angles to the armature spindle, and is provided with polar extensions. The armature coils are wound upon a flanged former of gun metal in such a way that the point of magnetic saturation shall only be attained when the machine is giving off a greater current than it is designed to produce. The periphery of the flanges of the gun metal former are provided with slots, into which are fixed pieces of insulating material for the reception of lateral copper bars. In another modification, the field magnet has a small iron core, round which is wound a highly insulated copper wire of such a length that it will have a very high resistance. A hollow cylinder of wrought iron of any convenient thickness is placed over the core and coil, and is afterwards wound with the same sort of wire as before. Over this cylinder and its coil is placed another cylinder, and any desired number of concentric cylinders and coils may be added, according to requirements. Three claims are made for the two forms of electromagnet, and for the armature.—No. 9853. July 13th, 1887. 8*d*.

CHEMISTRY.

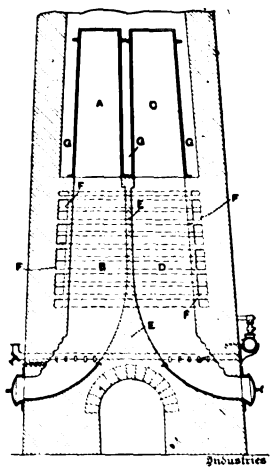
Carbonate of Iron.—*T. Thompson, Edinburgh.*—This invention involves a method of preventing the reaction of sulphate of iron and carbonate of potassium until the medicinally prepared mixture of these two salts has been introduced into the stomach. Their water of crystallisation is first driven off, and dehydrated salts are mixed with either almond oil, vaseline, or gum, in order to prevent any moisture coming in contact with them. The mass is then made up into pills, which may be covered with gelatine. The salts are thus prevented from absorbing any moisture until introduced into the stomach, and the reaction of the two salts which is required in producing the carbonate of iron is delayed. One claim is made for keeping the moisture out by means of the medium mentioned.—No. 5419. April 14th, 1887. 6*d*.

Oxides of Iron.—*E. A. Jones, Middlesbrough, and F. F. Jones, London.*—This invention relates to the production of red and brown pigments, consisting of oxide of iron, from the scale which falls from the surface of iron when subjected to the operations of hammering and rolling. The scale is first pulverised, and then converted into sulphate by the action of oil of vitriol. The further treatment consists of calcining the sulphate in a furnace in order to drive off the sulphur. The furnace employed is of considerable height, and the powdered sulphate is fed from the top, so that it falls through the entire height. A pipe is provided at the lower end for the introduction of heated air, the supply and escape of which is regulated so that the pressure in the interior of the furnace shall be greater than that of the atmosphere. Cross bars are arranged in the inside to retard the fall of the sulphate, and a grate at the bottom serves to maintain the furnace at a suitable temperature. In a modification of this process, the pulverised scale is subjected to the action of a stream of heated air charged with acid or surcharged with oxygen, without the previous application of sulphuric acid. Three claims are made.—No. 7761. May 27th, 1887. 6*d*.

Glue.—*T. P. Milligan, South Orange, New Jersey, U.S.A.*—The glue stock is first washed in cold water, and afterwards with hot water. During these processes the wet stock is placed in a basket made of wire or rattan, or of any porous material. The receiver and the stock are then plunged in a tank of boiling water, and the stock almost instantly contracts and hardens, and loses about 40 per cent. of water. The shrinking of the stock can also be effected by directing a jet of steam over a thin layer of stock placed on a slanting floor. The shrunk stock is conveyed to a loft which is heated by steam. The temperature of the air is regulated between 125°F. and 170°F., as this is sufficient to melt the tallow and extract it from the body of the stock. When the stock is bone dry it is subjected to a bath of boiling alkali in order to remove the grease and tallow; and after the alkali has been rinsed off by cold water, the stock is ready for a final bath in a solution of alum. When the glue has remained in the alum for twenty minutes it becomes hard and ready for use. Seven claims are made.—No. 3393. March 6th, 1888. 6*d*.

Separation of Fusel Oil.—*I. Trauber & G. Bodländer, Hanover.*—In separating the fusel oil from aqueous wood spirit or ordinary alcohol, the inventors saturate the liquids with sodium carbonate, ammonium sulphate, or other salts. This mixture separates out into two strata, the upper one containing the fusel oil, and the lower one being a mixture of spirit and salts. Two claims are made.—No. 8387. June 10th, 1887. 6*d*.

MISCELLANEOUS.



Guillotine Machines.—*H. H. Leigh, London. (P. J. Timoulin, Paris.)*—The inventor discards the use of wood and compressed paper for the tables of guillotine machines, and substitutes celluloid for them. The wood and paper tables become worn too rapidly; the celluloid also becomes worn, but it can be readily repaired by a composition specially invented. This composition is prepared by dissolving celluloid in a solution of collodion, pyro-acetic acid, or alcohol. Two claims are made, for the employment of celluloid, and for the composition for repairing it.—No. 9910. July 14th, 1887. 6*d*.

Metal and Asphalt Structures.—*W. Gürtler, St. Petersburg.*—A pattern of the structure is made of wood, and by its aid a frame work of iron and wire is woven in such a manner that the pattern forms a core; between the core and the frame work, sufficient space is left for forming the inner coating of asphalt on the frame work. The hot asphalt is applied on both the inner and the outer surface of the frame work, and it is pressed between the interstices. When the asphalt is cool the cores are removed and the surfaces smoothed. The metal frame work for tanks, pipes, or railway sleepers may consist of two helices of wire wound in opposite directions, and of vertical or longitudinal bars, which are arranged at distances apart between the helices, and securely attached to the wire. One claim is made for the manufacture of structures of metal frame work and asphalt, as described.—No. 7134. May 16th, 1887. 8*d*.

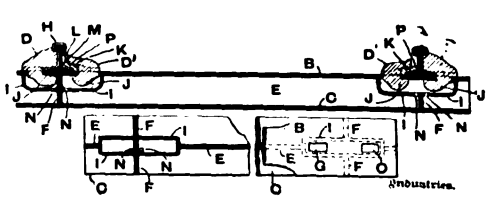
Utilisation of the Waste of Grain Mills.—*L. Rappaport, Breslau, Germany.*—The waste of flour and other mills, which consists of poisonous and useless seeds, has been found to contain a certain amount of oil and wax. These products can be extracted by means of mechanical pressure, or by the application of certain chemicals such as benzine, naphtha, ether, and the like. Four claims are made for the utilisation of the waste by these two methods.—No. 5270. April 9th, 1887. 6*d*.

Weaving Pile Fabrics.—*G. Burtscheidt, Dülken, Prussia.*—The object of this invention is to produce a pile fabric in a power loom, which shall have as firm and erect a pile as the hand made fabrics. For this purpose the inventor makes use of a binding in which the pile thread in the upper and lower grounds is bound between the two upper and lower warp threads. One claim is made.—No. 3587. March 8th, 1888. 6*d*.

Distilling Shale.—*R. M. Fraser & J. Snodgrass, Pumpherston, Midlothian.*—In the retorts used for distilling shale, the shale is passed down through them in a continuous stream; the oil is driven off principally in the upper parts, while in the lower end of the retort the shale is more highly heated, in order to extract the ammonia. The lower part is made of fire brick, and is heated by gas which traverses the flues in the walls of the

retort. In the figure A B C D represent a pair of retorts, the parts A C being made of cast iron, and the lower parts B D of fire brick. The retorts are separated from one another by a thin partition E. The flues F are formed round the lower parts B D for the passage of ignited gas, which afterwards passes into the oven space G surrounding the retorts A C. By this arrangement any overheating of the middle parts of the lower parts is avoided, and the heating of the two retorts is made more equal. The inventors claim in primary shale distilling apparatus constructing the heating flues of each pair of retorts on three sides, and separating the retorts by a partition which does not contain any flues.—No. 7867. May 31st, 1887. 8*d*.

Carding Cloth.—*H. Gerdes, Aachen, Germany.*—The ordinary cloth soon becomes useless by the carding teeth becoming bent outwards at their ends. The inventor has designed a new form of teeth, which will be more durable. The teeth are given a backward curve underneath in the joint piece of the two limbs; the bend is so great that the curve of one row meets the curve of the other row, and, consequently, the joint piece of one limb is held by the joint piece of two other limbs. Hence the joint piece of the limb lies with one surface on the drum, and the teeth stand free; the cloth or leather only serves the purpose of keeping the teeth upright in their proper position. The curve also prevents the teeth from bending outwards, because they are curved in two different planes. The giving way of the teeth is thus entirely prevented, even if the cards are drawn up loose. Two claims are made for the arrangement of the backward curve.—No. 2669. February 22nd, 1888. 6*d*.



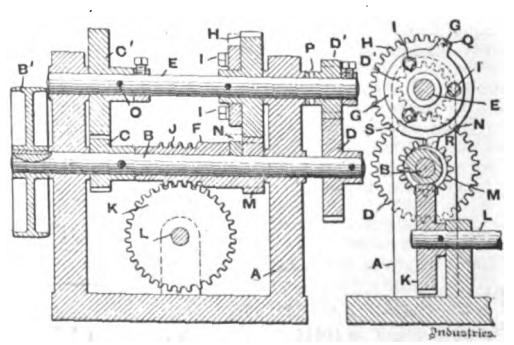
UNITED STATES PATENT ABSTRACTS.

Obtaining Alumina from Clay.—*F. J. Seymour, Findlay, Ohio.*—The process for separating alumina from clay described in this invention consists in first mixing the clay with a deoxidising agent and a flux and with copper, or some other metal of greater specific and atomic weight than aluminium, and in heating the mixture in a furnace. The mingled oxides which come off from the heating chamber are cooled and separately condensed. The silicia is first collected, and afterwards the alumina, together with the oxide of the other metal. Two claims are made.—No. 382197, dated 1st May, 1888.

Removing Fibre from the Seed.—*W. F. Corne, Cambridge, Massachusetts.*—A current of air is employed to blow the material against a rotating toothed surface inside the machine, and the same current of air is used for removing the resulting fibre from the machine. The casing over the rotating toothed surface is divided into a series of communicating pockets, each provided with a worm; the material passes successively through the pockets in its course through the machine. The pockets are separated from one another by check bars which have fingers protruding between the saws, in order to assist the latter in supporting the material and to prevent it from being carried beyond the check bars by the saws. Five claims are made.—No. 381616, dated 24th April, 1888.

Automatically Controlling the Supply of Water or Gas.—*L. Weil, New York.*—This invention relates to a method of automatically cutting off the supply of water or gas in a building or room when the doors are closed. An electric circuit and electromagnet are so arranged that when a certain mechanical movement such as the closing of the door takes place, the circuit is completed, a bell is rung, and the stem of the controlling valve is attracted by the magnet. There are seven claims for this arrangement.—No. 381866, dated 24th April, 1888.

Metallic Sleeper for Railways.—*H. L. de Zeng, Geneva, New York.*—The upper figure shows a vertical longitudinal section of the sleeper, and the lower figure a plan and a horizontal section of its ends. The sleeper consists of an upright central web E and a top and bottom flange B and C; and underneath the rails are two cross flanges F and the box enclosures I, the whole being cast in one piece. The mortises G O are made



in the upper flange for the reception of the clips D D¹. In securing the rails to the sleepers, the clips D D¹ are inserted through the mortises, and a wedge P is placed as shown in the upper figure; the flange L intervenes between the rail and the clip D¹, and a headed key K, sliding in a groove in the wedge, keeps the clip D¹ firmly fixed in its place. Nine claims are made for the sleeper and for the fastening.—No. 380623, dated 3rd April, 1888.

Softening and Renovating Leather.—*L. C. de Villiers, Brooklyn.*—The present invention relates to a process for softening and renovating all kinds of leather. The articles to be treated are immersed in a mixture of soft water and salts of sorrel, with a definite proportion of oil, ammonia, and castile soap which is quite free from potash. After remaining in this solution for some time the leather becomes soft and pliable. One claim is made for the composition of this solution and for its application.—No. 381680, dated 24th April, 1888.

Knitting Machine.—*C. J. Appleton, Elizabeth, New Jersey.*—The improved machine is intended for straight knitting, and includes a set of horizontal and a set of vertical needles, with a yarn guide for each. The cams which operate the needles are so constructed and arranged as to cause the needles of each set to form the yarn supplied to them into rows of plain loops, and to interlock these loops with the corresponding loops formed by the other set; the loops of one yarn are made to lie wholly upon one face of the fabric, and the loops of the other yarn wholly upon the other face. Three claims are made.—No. 381898, dated 1st May, 1888.

Wire Netting Machine.—*B. Scarles, Clinton, Massachusetts.*—The present invention relates to a mechanical movement which is more particularly applicable to wire netting machines, and its object is to impart to the shaft L an intermittent rotation from the driving pulley B¹. The spur wheels C and D are fixed on the shaft B, and the pinion H on the shaft E. The pinions C¹ and D¹ are loose upon the latter shaft, and either of them may be fastened to the shaft by means of screws, according to whether the shaft E is to be rotated slower or

faster than the shaft B. The sleeve F fits over the shaft B, and carries a spur wheel M, a worm J, and a finger N. The wheel H carries a mutilated gear, as shown, and a projection G¹ to catch against the finger N. The worm J gears with a worm wheel on the shaft L. By the mechanism as described, an intermittent rotating motion is imparted to the shaft L. Two claims are made for the combination of the pinions C D C¹ D¹, the mutilated gear, and the projections G¹ and N, with the sleeve and worm gear.—No. 380666, dated 3rd April, 1888.

The full specifications of the British and United States patents, and the Official Journals of the German Patent Office, from which the above abstracts have been compiled, and the Official Journal of the United States Patent Office, may be seen by subscribers and clients at the Reading Room, Manchester Office of Industries, *where also Patent Indexes from* A.D. 1617 *may be consulted. Copies of the British specifications may be obtained on application to* H. Reader Lack, Esq., *Comptroller-General, Patent Office, Southampton Buildings, London, W.C. The published price must be remitted, together with a sum sufficient to cover postage, which may be reckoned at ½d. for every* 10*d. or fraction of* 10*d. Remittances exceeding one shilling must be made by Post Office Order.*

THE IRON AND STEEL INSTITUTE.

In our previous issue we brought the report of the last meeting of this Institute down to the conclusion of Wednesday's proceedings. The first paper read on Thursday morning was by Mr. James Johnston, on

Continuous Moulding Machinery at the Works of M. Godin, at Guise, France.

This paper was prefaced by a short history of the works and an account of the economical and social conditions under which they are carried on. The paper itself contained a minute description of the machinery used in the moulding and casting of iron ranges for cooking stoves and other domestic purposes. Some diagrams were placed upon the wall, but these were drawn to so small a scale that it was impossible to distinguish the details, and consequently much of the value of the paper was lost to the hearers. We shall not attempt to abstract or reprint the paper at the present time, but shall do so when we have obtained a copy of the diagrams. There was hardly any discussion on the paper itself, most of the speakers pointing out that it was impossible to discuss the paper in the absence of specimen castings, or of sufficiently large wall diagrams to be seen by everybody in the room. In this connection Mr. Jeremiah Head suggested to the Council of the Institute that the means at the command of the Institute would be quite adequate for the appointment of a competent staff of draughtsmen organised in a similar manner to that of the Institution of Mechanical Engineers. These draughtsmen would assist authors by preparing wall diagrams for their papers; or if authors preferred to make their own diagrams, the staff of the Institute would give them such directions that these diagrams might be of a suitable nature for their proceedings. It was finally resolved to defer the discussion on Mr. Johnston's paper until the next meeting, when the author promised to exhibit specimen castings, and by which time the diagrams will have been published in the Proceedings of the Institute.

The next paper read was by Major L. Cubillo, of the Spanish Artillery Ordnance Works, Trubia, on

The Manufacture and Treatment of Steel for Field Guns.

A reprint of this paper will be found in another part of the present issue. The discussion was opened by Mr. Walker, of Leeds, who spoke in strong terms against the present practice pursued by the Government in testing guns. In his opinion the strains which were put on our guns in testing were so great as to permanently injure them, and he pointed out that the Germans do not test their guns in the same barbarous manner. It was, no doubt, very gratifying to the manufacturer of a gun to find that it would throw a shot to a distance of twelve miles, and produce a muzzle velocity exceeding anything which had been done before; but the ultimate object of our guns was not to perform extraordinary feats, but to protect the country, and the guns after having been tested in this manner were not reliable. He did not agree with the author regarding pot steel, and thought that if they wished to make steel of the very highest quality it was necessary to make it in the crucible and start with the very best materials they could obtain, carrying out the process of steel making step by step, and in the most careful manner. If they had to deal with very large ingots the steel should never be allowed to cool down, but must be worked with the least possible delay. It was only in this way that they could avoid the variations of carbon in different parts of the piece, which variations greatly impaired the strength of the gun. His firm had made some very large steel castings, and to get uniformity they had found it necessary to run the metal in at the bottom of the mould, and to use large heads so as to put the whole of the metal under considerable pressure. The results obtained with this method were very satisfactory. He had no doubt that the most perfect steel castings could be obtained by the method suggested by Sir Henry Bessemer, and so ably carried out by Sir Joseph Whitworth, of compressing the steel whilst still in the liquid form, or even when in a semi-liquid form. This was much preferable to letting the casting get cold and re-heating it afterwards. The process of cooling the inside of the ingot, referred to in the paper, was not a good one, and they would not improve the quality of the steel by running cold water through the hot tube. He preferred to improve the quality of the metal by giving it plenty of work, and the time was not far distant when, instead of the noisy and rattling steam hammer, which shakes the inside of the steel to pieces, the metal would be quietly kneaded into compact and solid masses by the hydraulic press. His firm had made a press for Sir John Brown, which was used in the manufacture of some large ingots, which were ultimately worked into shafts, and even the workmen who turned these shafts on the lathe noticed the difference between the material thus produced and that usually obtained when the steam hammer was used. In point of cost the press has also a great advantage, and the speaker thought the same work could be done for one-fourth of the expense as compared with that of the steam hammer.

Mr. Edmonds, of the Woolwich Arsenal, regretted that General Maitland was not present to discuss the subject of testing the guns by heavy charges. The speaker, however, did not agree with Mr. Walker in his criticism, and pointed out that it was the usual practice amongst engineers to test machinery beyond its working load. Opinions might differ as to the amount of the test, but they were all agreed that such testing was a safeguard. When guns were properly made they were in the tests never strained beyond what they were able to stand. The object of proving the gun was to ascertain that all its parts were of reliable material, and had been properly made. In his opinion it would not be fair to the gunners and to the country to test a gun only with the usual charge of powder and then send it out for service. He noticed that the paper simply dealt with crucible steel, and with only very small guns. No difficulty was experienced in making steel for small guns, and he considered that almost any kind of steel would do for that purpose. The steam hammer would at no very distant date be superseded by the hydraulic press, and it would only be by using the latter that they would obtain good work. He did not altogether agree with Mr. Walker that a very large amount of work must be put upon the steel. If that were done, and if the forging were drawn out into a long piece and then tested both longitudinally and transversely they would find a great difference, not only in the strength of the material, but also in the elongation. He contended that this was due to the hammer, and that if the hydraulic press were employed instead a much more homogeneous material would be obtained. With reference to the tempering of the steel, he was of opinion, until recently, that this improved the metal; but from a few recent trials which he had made he was not now so sure that this was the case, and in this connection he was about to make an exhaustive series of experiments.

Mr. E. H. Carbutt said that he had for the last eighteen months had great doubts as to the efficiency of oil tempering, and he thought that when more experiments had been made it would be found to be rather a question of annealing. He had been a member of the committee appointed by the Government, and in this capacity he had visited all the works in this country where forging presses were employed, and he could confirm all that Mr. Walker had said regarding the superiority of the press over the steam hammer. The first press put up by Sir Joseph Whitworth owed its existence to what at the time seemed a misfortune. The speaker had made a large steam hammer for Sir Joseph Whitworth, but some neighbours complained of the noise and vibration, and this led Sir Joseph Whitworth to turn his attention to the question of using a press instead. The advantage of the press was that the centre of the ingot was not wasted, as the tube could be worked on a large mandrel, and thus there would be pressure inside as well as outside. He had recently ascertained from a Russian officer that at the Russian Government Works they used a Whitworth press for compressing steel in the fluid state. Anybody who had seen the beautiful exhibits of Sir Joseph Whitworth & Co. at the Manchester Exhibition must have come to the conclusion that the press is the instrument of the future. The speaker could not agree with Mr. Walker regarding the advantages of pot steel over Siemens-Martin or open hearth steel. When they came to deal with masses up to 50 tons, they could not make as good an ingot with pot steel as they could with the other material, and it was well known that every tube with which difficulties had been experienced at Woolwich was made of pot steel. He also took an entirely different view from Mr. Walker on the question of testing guns. He himself had blamed the Government for not having tested sufficiently, and he contended that it was far better to occasionally over-test and destroy a gun with a view to ascertain exactly what their guns would stand than to go on spending enormous sums, and remain in ignorance of the real nature of these weapons. If the country was to maintain its position, it could only do so by continually improving the guns, and this was impossible without experiments.

Sir Henry Bessemer said that his attention was first directed to the manufacture of iron and steel when he endeavoured to find a suitable metal for guns. He had come to the conclusion that a sound steel casting could not be made without pressure. In an ordinary iron casting they had a pressure of at least 15lb. per square inch, being that of the atmosphere; and if they attempted to cast in a vacuum, the casting would be extremely spongy. His first idea was to force a ram into the liquid metal, and thus put pressure upon it; but there were obviously conditions under which this method could not be applied. For instance, a locomotive crank could not be made in this way, as the webs would simply close up under the pressure of the ram. The method was also inapplicable to the casting of a cylinder, and he therefore suggested another method, under which the whole mould would be put into a closed steel cylinder, and after casting the cylinder would be put into communication with vessels containing gases under high pressure. By this means they would get a uniform pressure over the whole area of the casting, precisely as they now get a pressure of 15lb. over the area of ordinary iron castings. He had ascertained by experiment that if an inch cube of steel were laid upon a steel ingot heated to the usual forging heat, and if a pressure of 3 or 3½ tons were applied, the cube would be forced bodily into the mass of the ingot, and would disappear. He therefore came to the conclusion that a pressure of 4, or, at the outside, of 5 tons to the square inch would be ample to compress the steel to as great an extent as it was compressed by the steam hammer. The steam hammer, although an excellent instrument for small forgings, had the great defect when applied to large forgings of compressing only the outer portions, since the inertia of the large mass underneath would prevent the pressure from being transmitted to the interior. With the hydraulic press this difficulty vanished, and they could operate on the mass equally in all directions. He believed that if the casting while still fluid were subjected to a pressure of 5 tons, or even more if desired, it would when solidified be so dense that no forging or other method of subsequent compression would be required.

Mr. J. W. Spencer, who has had great experience with both crucible and Siemens steel, thought that better results could be obtained with the latter than with the former. He admitted that the press might be a better instrument than the hammer for large masses; but he thought that the best way to get over the difficulties connected with the treatment of large masses would be to cast them, not in the form of an ingot, but more nearly in the shape in which they were ultimately required. He agreed with the President in considering tempering an objectionable practice, and in all probability the material was rather injured than improved by it. The speaker next referred to Major Williamson's plan of building up guns in layers which contained different amounts of carbon. The hard steel would be put into the centre, and protected by milder steel on the outside, and the whole would be heated together to a welding heat, and then treated with the steam hammer, the press, or the roll. The presence of the mild steel on the outside would protect the inner layers of hard steel from the action of the air.

Mr. J. Y. Hall thought that heavy guns could be made in the form of plain steel castings equally as well as in their present built up form. It would, however, be necessary to apply a judicious system of tempering and annealing, so as to distribute the strains equally throughout the mass of the metal.

The President thought that steel makers had yet something to learn, both as regards uniformity of material and economy in manufacture. When they considered that 35 per cent. of the ingot had to be cut off at the top, and 5 per cent. at the bottom, they would agree with him that improvements in their method of producing steel were desirable. He agreed with Sir Henry Bessemer's suggestion to consolidate the casting by gaseous pressure, after which no subsequent working could give the metal greater strength or endurance. The records of strength and elongation in the paper were obtained by using a testing machine of only 60 tons, and on this account they were not so reliable as might be wished. The results obtained with a small test piece of about half a square inch area could not be taken as an indication of what would be found if test pieces 4in. or 5in. in diameter were pulled asunder. In the smaller test pieces, the outside and inside were affected almost equally; but with large test pieces the stresses would not reach the interior so quickly as they reached the exterior. If they had a machine sufficiently powerful for testing large pieces, they could arrive at a definite conclusion whether oil hardening was advantageous or not. It had been stated that a large amount of work put on to the metal would increase its strength and endurance, and they all knew that a 30-ton metal when drawn into wire might easily have a breaking resistance of 60 tons; but they should remember that this work took place when the metal was cold, and was, therefore, different from the work usually put on forgings. Moreover, the increase of strength was only attained with comparatively small masses, and if the results were applied to large masses they might be misleading. He could not agree with Sir Henry Bessemer's objection to the use of a ram for producing the pressure in the casting, for if the pressure were applied whilst the metal was still fluid, it would be transmitted to all parts of the casting equally. He had no doubt that the press would ultimately replace the steam hammer for large work. It was not only quicker in action, and produced a better forging, but it also minimised waste. He had seen a magnificent steel shaft, 17in. diam., and of great length, made by Sir Joseph Whitworth under a press, and the work was turned out so true that it required only $\frac{1}{16}$th of an inch to be turned off the surface to finish it. Referring to the question of testing guns, he deprecated the method of putting abnormal strains upon the material,

Digitized by Google

because of the permanent injury which may result from it. The test strains should not greatly exceed the greatest strain which could by any chance come upon the metal in actual service. The Admiralty had already abandoned the old method of testing boilers to twice their working pressure, and were now satisfied with a test pressure equal to the working pressure plus 90lb. per square inch. This was obviously a step in the right direction, and he thought that a similar system might be adopted in testing guns. It was out of the range of possibility that a gun which in regular service had to stand a pressure of 20 tons to the square inch could at any time be strained to double that amount. It would therefore be sufficient to simply test the gun with such a charge as to increase the working pressure by a moderate and definite amount, which would serve to show that the material was sound and that the gun was properly designed and made. He had for some time held the opinion that tempering in oil was not only undesirable, but absolutely injurious. A paper was read on the subject by Professor Akerman at their Düsseldorf meeting, and afterwards that gentleman sent him specimens the tests of which he had intended to publish in a paper at the Institution of Civil Engineers, but pressure of other work had prevented him from writing this paper. He had, however, made 180 tests, and had found, almost without exception, that oil tempering when applied to large masses proved injurious. They must remember that in a gun there were concussive strains, and for this reason it was undesirable to employ a material in which there already existed internal strains. Some years ago it was considered satisfactory if a gun tube had a strength of 20 tons circumferentially and of 12 tons longitudinally, whilst now they could obtain a metal carrying from 28 to 30 tons in both directions. He, however, did not think it wise to push the increase of strength too far; they might get a lighter gun with a higher carbon metal, but if he had to work a gun in a turret he would prefer the gun to be made of a somewhat lower and more ductile metal, because if it came to grief it would do less damage than the stronger metal.

The next paper read was by the same author on

Steel Castings for the Manufacture of Guns.

In this paper the author pointed out that the high price of steel forgings for the manufacture of guns and the expensive plant required in the process had induced many artillerists and engineers to consider whether it would be possible to produce reliable artillery from steel castings. If at the end of a heat of the Martin-Siemens process ferro-silicon-manganese be added to the bath, a casting can be produced containing ·28 per cent. of carbon, of 29 tons strength and 5 per cent. elongation. This metal differed widely from forged steel tempered in oil of the same percentage of carbon, it being most deficient in ductility; yet this cast steel was very superior to cast iron, having twice the tenacity and eight times the ductility. Its point of fusion being higher, it was also more adapted to resist the high temperature produced in the bore of the gun when fired. It would thus appear that although cast steel guns could not compete with forged guns, they had yet a great advantage over iron guns, which were still used in some countries for reasons of economy. In the manufacture of howitzers, which are subjected to relatively small pressures on firing, steel castings could be employed without inconvenience.

In the casting, during the process of cooling, crystals were formed, and it was well known that their size depends not only on the rapidity of cooling, but also on the greater or lesser mobility of the molecules when cooling. If the casting be heated to a temperature greater than the point B of Tchernoff's scale, and then immersed in a refrigerating medium, the amorphous texture acquired by the steel at that temperature was preserved, and was practically the same as that of forged and tempered steel. When an ingot was heated to a temperature superior to the point B, and then worked by the steam hammer or the hydraulic press, the continuous mobility imparted to the molecules prevented crystallisation, and the texture of the metal was amorphous and fine grained. They would remember the paper read by M. Pourcell at the Vienna meeting, which demonstrated that it was possible by tempering steel castings at different temperatures to manufacture a metal which could compete with forged and tempered steel. The Terre-Noire Company, at the Paris Exhibition of 1878, also showed a cast tube which had fired one hundred rounds, and in which the deformations were smaller than those occurring in a forged tube equally tested; but the most practical and severe trials of tempered steel castings have been made in Sweden, at the Böfors Works. The materials charged in the Siemens furnace for the castings were the following:—

Swedish pig iron of superior quality	26
Spiegeleisen, 12 per cent. manganese	6
Swedish iron scrap	63
Ferro-silicon-manganese	5
	100

The percentage of carbon was ·37 in the first experimental gun, and the tubes and breech pieces were cast solid. After firing 322 rounds with extraordinary charges in this gun, five new guns were constructed, and the test pieces taken from the heads of the castings gave the following results:—

Percentage of carbon.	Elastic limit. Tons per square inch.	Tensile resistance. Tons per square inch.	Elongation. Per cent.
0·30	21·5	38·9	21·0
0·30	22·3	40·5	20·0
0·35	24·3	38·4	21·2
0·37	29·9	50·7	14·8
0·38	24·3	45·4	19·0
0·38	33·3	54·9	9·0
0·39	25·3	43·0	14·0
0·35	15·2	38·63	15·0

Four of these guns, three of which were 3ft. 2in. and one 4ft. 6in., were submitted to trials. One of them burst at the round 2152, another had its breech piece cracked at the round 2154, whilst the third only showed a small expansion in the most advanced part of the powder chamber. These results seemed to indicate that castings properly tempered could be employed without any risk in the construction of field guns, and the reason they were not employed for larger guns seemed to be the fear that notwithstanding all precautions observed in the casting process, there might be left in the inner parts of the tubes and breech pieces some cavities which would weaken them.

Recently, in the United States, a 6in. Bessemer steel gun had been cast with complete success; but the author did not know if this gun would be built up or made of a single tube, nor whether it would be tempered at different temperatures. He did not consider that the Rodman process would present any inconvenience when applied to cast steel guns; but owing to the difficulty of establishing the ratio between the water passed through the bore in a certain time, and the initial tension required by the different films, he considered the built up system the only method of producing guns so powerful as the physical qualities of the steel permit. When a built up gun bursts, the accident was not necessarily the fault of the system, but might be due to bad shrinkage, or defective design, or to the bad quality of the steel.

The discussion on this paper was opened by

M. Gautier, who referred to a paper he had read on the same subject at a previous meeting. He had seen the first gun made by M. Pouriel, at the Terre-Noire works. Rodman's process of cooling the metal by a stream of water sent through the bore of the gun had been found of great advantage in cast iron guns, but he did not know whether it would be equally valuable in steel guns. It would be remembered that the first wrought iron armour plates were made in France. They were only 4in. thick, and to avoid crystalline structure, they were brought to a red heat, and hardened in water. When they used mild steel, they were still troubled by the crystalline structure, and to avoid this they hardened in oil; but this was liable to produce cracks. Recently, the method of hardening in lead by dipping the plate into a bath of molten lead was introduced, and this would give the steel, with a high percentage of carbon, an intermediate condition between hardening and annealing.

Mr. J. A. Pease, as an advocate of steel castings, felt himself disappointed at the concluding sentence of the paper, which was to the effect that forged metal must be exclusively used in the construction of guns. This statement, which was perhaps made unintentionally, was completely at variance with the rest of the paper, which was evidently written to show that steel castings could be used for artillery purposes. The facts reported in the paper ought to outweigh the antipathy which many persons had to cast steel guns, and the speaker thought there was a good prospect for such guns.

Mr. J. W. Spencer was pleased with the results recorded in the paper. Some eight years ago a conference was held at Elswick, when he suggested to make a gun in the form of a steel casting, but Lord Armstrong laughed at the idea. At that time he was doubtless right; but since then events had shown that his original suggestion was feasible, and that it would ultimately come into use. At the last Newcastle Exhibition he had a cast tube for a 10in. gun, and tests made showed that the material was superior to the forged steel employed by the Woolwich authorities. He felt certain that cast guns could be made equally as strong as forged ones. They could cast very nearly to the size of the finished gun, and obtain a perfectly homogeneous material throughout the piece. He was totally opposed to oil hardening, and thought it moreover unnecessary, as another method had been invented which would produce the right molecular condition of the casting. He was, however, not at liberty to disclose that method.

Mr. J. D. Ellis also commented on the contradictory language of the paper, and confirmed the previous speaker's statement that steel castings could be made to stand almost as severe tests as forgings; but he would remind them that, notwithstanding all improvements, they would sometimes find at the bottom of the casting a few cavities which would weaken the piece, and might lead to a serious disaster. By the present method of making guns they could ascertain that the metal used was sound throughout, and for this reason he would not advocate a departure from the built up gun. He objected to the word tempering being used in the sense in which it was used in that discussion, as the process was not tempering, but simply one of hardening.

Mr. Edmonds, of the Royal Arsenal, drew the attention of the meeting to the fact that they were in reality discussing two questions, the first whether they should substitute cast for forged guns, and secondly, whether their guns should be all in one piece or built up. If they had a cast gun it need not necessarily be in one piece, and if steel makers could furnish them with castings of as good a material as the present forgings, he saw no reason why guns should not be made of this material, on the built up principle.

Mr. James Riley from his own experience felt satisfied that steel castings could be made equally as strong as forgings, and considering the heavy tests to which the guns were subjected, the presence of cavities in the casting and of weak spots would be immediately detected, so that the guns when they had passed the tests would be perfectly safe for service. He also directed attention to the fact that cast guns would be much cheaper.

Mr. E. H. Carbutt referred to the difficulty which the Government had in obtaining guns. They had now nine ships built, engined, and ready to go to sea, but no guns for them, and therefore he believed the authorities would be quite ready to adopt any improvements which would facilitate and accelerate the manufacture of guns. The reason they were behind with the guns was, that although they had sufficient forging power they were short of lathes where these heavy pieces could be turned, and if they could cast some of the outer rings it would greatly lessen the labour in turning, so that guns could be produced more quickly.

After a few words from Mr. Walker and the President, the discussion was concluded, and a paper was read by Messrs. Pattinson and Stead on

The Behaviour of Arsenic in Ore and Metal During Smelting and Purification Processes.

In this paper the authors pointed out that the literature on the subject was extremely meagre. They had made a special study of it for some time, and they now laid the results of their investigations before the Institute. It was well known to many analysts that arsenic in small quantities was widely distributed, traces of it being found in most ores, especially those of a sulphurous nature, and a table was given of various ores in which the arsenic varied from nothing to over 1 per cent. In pig iron the average quantity of arsenic is about ·03 per cent., but may occasionally rise to ·15 per cent. It was a prevalent idea that arsenic might be expelled from the ores when they were smelted, and in order to test this point experiments were made with arsenical pyrites calcined in open hearth vessels with free access of air, with and without the presence of lime, and in closed vessels in a reducing atmosphere. These experiments showed that the greater part of the arsenic was rapidly removed in the absence of lime by open calcination, but that it was difficult to expel the last traces, and that practically no arsenic was removed from iron and manganese ores when only small quantities were present to begin with. Lime was found to have an important influence in preventing or retarding the volatilisation of arsenic. A further series of experiments was made to ascertain the behaviour of arsenic in ores during the process of smelting in the crucible and in the blast furnace, and the majority of these experiments showed that nearly all the arsenic introduced with the ore was also found in the pig. Careful examination of the flues of blast furnaces had not revealed more than the presence of traces of arsenic in the dust. The authors had analysed some of the iron ore deposits in the neighbourhood of Civita Vecchia, which contained a large percentage of arsenic. Near a disused charcoal blast furnace they found several small pigs of metal, which were carefully analysed, and from the results of these analyses they had come to the conclusion that practically speaking the whole of the arsenic introduced into the blast furnace in iron ores was concentrated in the pig produced, and did not go off with the escaping gases, as was often supposed.

The next point dealt with was the behaviour of arsenic in the process of converting pig iron into steel. The authors showed that no arsenic was removed by the acid Bessemer process, and a similar result was found with the acid open hearth process. With the basic Bessemer process the blown metal contained a slight increase of arsenic, which was obviously only a relative increase due to the removal of other substances, and with the basic open hearth process similar results were obtained, a metal containing 3·21 per cent. of arsenic before treatment containing 3·39 per cent. after treatment.

Regarding the physical effects of arsenic, the authors pointed out that hematite pig made in the Cumberland district, although containing ·04 per cent. of arsenic, was exceptionally suitable for making steel, and that therefore this quantity of arsenic would not have a deleterious influence. They had also met with very good mild steel containing as much as ·2 per cent. of arsenic, and they concluded therefore that this element had not the same injurious properties as phosphorus. On the whole the presence of arsenic in larger percentages must, however, render the material brittle. The paper concluded with a description of the method of determining the percentage of arsenic in iron and iron ores.

The discussion of this paper was taken together with that on a note by Messrs. F. W. Harbord and Alexander E. Tucker on

THE EFFECTS OF ARSENIC ON MILD STEEL,

in which the authors pointed out that no systematic experiments had as yet been made to determine the effect of arsenic on wrought iron or mild steel. They had investigated this question, and adopted the following method in their researches: A rich alloy of arsenic and iron, practically free from other metalloids, was first made by heating drillings of mild basic steel to redness, and then dropping metallic arsenic into the pot. The alloy was fusible at a full red heat, and was re-melted to insure uniformity, and poured out on to an iron plate. Varying quantities of this alloy were melted in an ordinary 56lb. clay pot, and mild steel, taken from a Bessemer converter, was teemed into the pot from an ordinary casting ladle, and in this way a series of twelve alloys of basic steel varying from ·07 to 1·2 per cent. was obtained. Some samples were also made with blown metal; but on account of red shortness these were discarded. The small sample ingots were rolled down to 1⅛in. round bars, and the behaviour of each was as shown in the following table:—

EFFECT ON ROLLING.

No.	As.	Effect.
0	nil.	Rolled perfectly.
1	0·070	„ „
2	0·093	„ „
3	0·171	Rolled fairly.

The bars were cut into suitable lengths for tensile tests, cold bending, plating, and welding, and by these tests the authors found that a percentage of arsenic not exceeding ·170 did not appear to affect the bending properties of steel at ordinary temperatures. Above this percentage cold shortness began to appear, and rapidly increased until with a percentage of 1 per cent. the metal became exceedingly brittle. If ·350 per cent. of arsenic was present it was found impossible to make a sound weld. Below that quantity the metal could be welded and easily plated out at full red heat. A percentage of arsenic not exceeding ·66 per cent. raised the tensile strength in a marked degree, but above this percentage the strength again diminished. Arsenic lowers the elastic limit of steel in a marked degree. On the whole, the authors considered the effect of arsenic on iron and steel as the reverse of beneficial.

In the discussion which followed the reading of these papers, Mr. Blair, of Stockton, read a long statement in which he referred to previous investigations made by chemists on the effect of the rarer minerals on iron and steel, and pointed out that the effect of those elements which hitherto had not been usually taken into account might at times be of great importance. English metallurgists were generally satisfied when they had determined the quantity of carbon, phosphorus, sulphur, silicon, and manganese; but they did not, as a rule, test their samples for the presence of arsenic, copper, and other elements. German and Swedish chemists, on the contrary, were very careful to search for almost every element which might possibly be contained in the sample, and if they followed that example they would not hear so much of the mysterious behaviour of steel or the treachery of this material: terms which were really applied to hide our ignorance. The more closely English chemists would push their inquiries regarding all the elements which might be contained in steel, the more perfectly would they understand the behaviour of this metal.

Mr. E. Riley had taken great interest in tracing phosphorus and arsenic in connection with steel and spiegel for the last twelve months. He would give the credit of having first obtained arsenic out of pyrites over thirty years ago to Dugald Campbell, who had also discovered the presence of this element in hematite ores. Some ten or twelve years ago there was found a large quantity of watery deposit in a pocket in a hematite district, from which he had made some steel, which contained a large quantity of arsenic. He made the steel into drills, but found it very brittle. The speaker pointed out that arsenic occurred very frequently in spiegel and ferro-manganese, and many of the differences found in analyses might be due to the fact that arsenic was occasionally estimated as phosphorus. In their present method of determining phosphorus the whole of the arsenic was eliminated as chloride of arsenic, provided they boiled the solution for a sufficient time; but if they neglected this precaution part of the arsenic present would be estimated as phosphorus, and thus they might get in a certain sample ·055 per cent of phosphorus, whereas, in reality, more careful analysis would have shown ·013 per cent. The practical bearing of this question was of great importance, since it had become a common practice to guarantee the phosphorus to be below a certain point when selling cargoes of iron and iron ore, and it was therefore important that the phosphorus should be ascertained separately from the arsenic. He had recently a cargo of iron ore submitted to him and he made the phosphorus ·037 per cent. The same cargo was also submitted to Messrs. Pattinson & Stead, who made the phosphorus ·044 per cent., and this discrepancy he considered was not too great for practical purposes. They all knew that they could not determine phosphorus to a $\frac{1}{1000}$th per cent., and they would be quite satisfied if they could determine it to $1\frac{1}{00}$th per cent.

Mr. E. Tosh confirmed the statement of the previous speaker, that arsenic was often mistaken for phosphorus in the usual chemical analyses applied to samples of iron and steel; but the investigations of Mr. Stead and of the authors showed that arsenic was not nearly so injurious an element from an engineer's point of view. Now, if iron or steel contained ·04 per cent. of phosphorus and ·04 of arsenic, it would be considered a good material; but if the arsenic were mistaken for the phosphorus, its percentage would be returned as ·08, and this material would be rejected. Sellers of pig iron had often to guarantee the percentage of phosphorus when exporting to the United States, and then it was a matter of great importance that the analysis should be so conducted as to show the percentages of phosphorus and arsenic separately.

The authors of these two papers did not reply to the discussion, and the last paper read at this meeting was by Mr. H. le Neve Foster, and descriptive of

A NEW INSTRUMENT FOR THE MEASUREMENT OF COLOUR, MORE ESPECIALLY AS APPLIED TO THE ESTIMATION OF CARBON IN STEEL.

This instrument is the invention of Mr. F. W. Lovibond, of Salisbury, and is intended for the accurate measurement or matching of colours. One of its applications is to obtain a permanent standard for the matching of carbons in steel by the well known Eggertz colour method or by Stead's alkali method. The instrument consists of a tube divided by a central partition which terminated at the eye piece in a knife edge; at the other end are two apertures alterable in size or shape by means of diaphragms. The two apertures are divided by the thick end of the central partition, which together with the sides is recessed by grooves into which can be placed standard glasses, each of a distinct colour and shade. Into one of the partitions is placed the trough containing the liquid which requires to be matched. Behind the apparatus is a white surface, and the whole is so arranged that the only light which can meet the eye of the observer must first pass in equal limits through the liquid in the gauge glass vessel in the one tube and the standard glasses in the other tube.

Found by Eggertz Method. Carbon per cent.	Found by Tintometer. Carbon per cent.

The observer inserts standard glasses until he sees exactly the same colour and the same shade of colour through both tubes, and after the observation he has only to read the figures on the standard glasses which he had to insert in order to find the percentage of carbon present. The author had worked with the tintometer, and gave various tables to show the degree of accuracy which can be obtained by its use. The best results as regards accuracy were obtained by dissolving half a gramme of steel in 10cc. of nitric acid of 1·20 sp. gr., boiling for twenty minutes, and then diluting with 50cc. of water. This liquid is put into a 1in. cell. For mild steel, this gave a colour which was easy to match. The figures obtained with various samples of steel by the Eggertz method and by the tintometer respectively, are shown in the accompanying table.

The author concluded his paper by an appeal to chemists to unite with a view to form a reliable standard for which in his opinion coloured glasses were eminently suitable.

There was no discussion on the paper, and after the usual formal proceedings, the meeting terminated. The next meeting of the Institute will be held in Edinburgh, on the 21st, 22nd, and 23rd August next.

THE "CLOSE GRIP" SASH FASTENER.

THE accompanying illustrations show an improved form of sash and casement lock, invented by Mr. W. K. Booth, 21A, Exchange Buildings, St. Mary's Gate, Manchester. The apparatus consists of a catch secured to the inner sash, and a pivoted lever fitted with a screw and attached to the outer sash. In fastening the window the lever is turned into the position shown in Fig. 2, and the screw

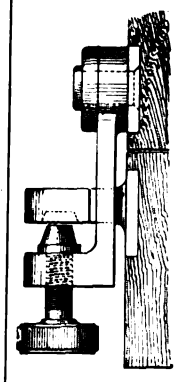

FIG. 1.

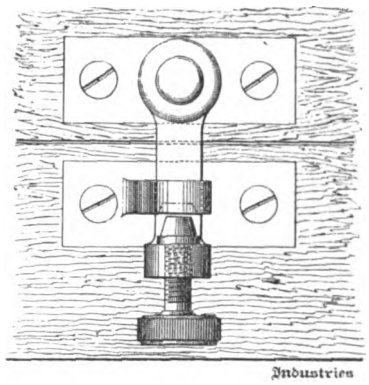

FIG. 2.

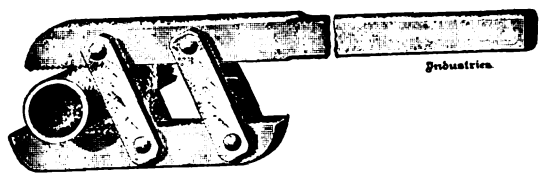
is made to engage with a conical recess provided in the catch on the inner sash, thereby forcing the sashes against each other. The advantages claimed for this arrangement are that the loose sashes may be tightened up in such a manner that the insertion of a tool for burglarious purposes is almost impossible, and that therefore the window cannot be opened from the outside without cutting the glass, and further that the upper and lower sashes are so firmly bound together that the objectionable clatter and noise often produced by the wind is altogether prevented.

MODERN HEAVY ARTILLERY.

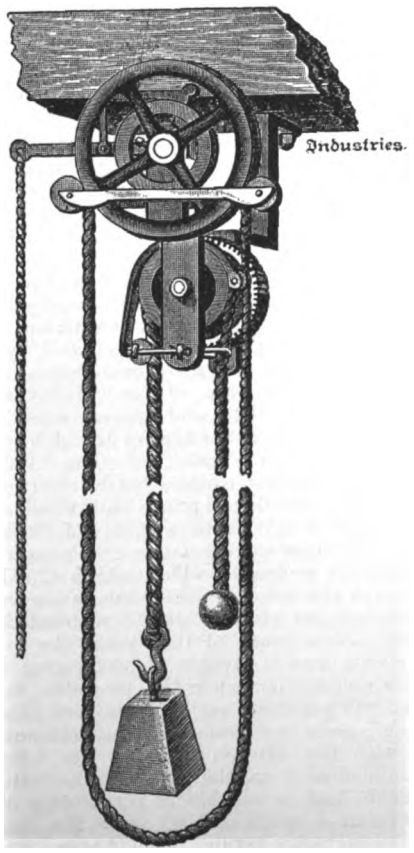


No limit can be fixed to the possibility of science, and with increasing mechanical ingenuity and improvements on existing types of ordnance we may expect that larger and more destructive weapons than have yet been constructed will be called into existence. Thirty years ago it was considered that no gun exceeding 5 tons in weight could be worked on the deck of a ship. To-day guns weighing 110 tons are loaded and manipulated on shipboard through hydraulic agencies with the greatest ease. Muzzle loaders have been superseded by breech loaders, and power and range are ever increasing. The 80-ton muzzle loading guns of the "Inflexible" are already considered obsolete, and are exceeded both in range and power by the newer type of breech loading 67-ton guns carried by the "Trafalgar." The "Inflexible" 80-ton gun is built of iron coiled around a steel tube, and is 27ft. long. The new 67-ton gun is built wholly of steel, and has a length of 36ft., with a calibre of 13·5in. The charge of powder used in the latter gun weighs 630lb., and provides the projectile, which weighs 1250lb., with as much energy at a range of 1000 yards as the projectile from the 80-ton gun possesses at the moment it leaves the muzzle. At a range of 1000 yards the projectile from the 80-ton gun is capable of penetrating 23in. of unbacked wrought iron, while the projectile from the 67-ton gun will penetrate rather more than 27in. The "Trafalgar's" guns are somewhat insignificant when compared with the 110-ton guns of the "Benbow." The projectile fired from the guns of the latter ship weighs 1800lb., and is capable of penetrating 35in. of wrought iron at a range of 1000 yards, the charge of powder used weighing 900lb. Our 110-ton guns have already been surpassed by the Krupp 118-ton guns, which were supplied to the Italian Government a short time ago. With these guns a wrought iron plate of 41in. in thickness can be penetrated near the muzzle, and 39in. at a distance of 1000 yards. Their length is about 46ft., and weight, including breech mechanism, 118 tons. They are made entirely of crucible steel, and are without trunnions,

Digitized by Google

the connection with the carriage being made by means of ring projections. During experiments with these weapons results were obtained which are stated to be the highest realised with any existing cannon. These achievements, however, are soon likely to be surpassed by the production of other monster weapons by Krupp of Essen. Designs for a 139-ton gun already exist, the projectile from which would be capable of piercing a wrought iron plate 45in. thick; and report says that a piece of ordnance to weigh 150 tons is in contemplation at Essen. What is the limit of weight of gun to be carried on shipboard? And when is all this rivalry in heavy guns to cease? A few months pass away, and what was new and startling becomes old. Reasoning from the past, it would seem that even our 100-ton guns may soon fall into comparative disrepute, and others more powerful may hold supremacy.

A NEW PIPE WRENCH.



The accompanying illustration, which is taken from our American contemporary the *Iron Age*, represents a new pipe wrench, constructed by the Ellrich Hardware Manufacturing Company, Plantsville, Connecticut. This wrench is made of the best tool steel, and is self adjusting within a limited range. It consists of one long bar of

steel as a handle and a short steel bar connected to it by means of two short bars, which freely swing round the four rivets shown. The advantages claimed for this tool are its simplicity of construction and the firmness of grip on the piece operated upon. This wrench is likely to prove a useful tool, especially in places where only a limited space for working is available, as it may be used in the same manner as a ratchet brace.

IMPROVED HOIST.

The accompanying illustration, for which we are also indebted to our American contemporary the *Iron Age*, represents an improved rope hoist constructed by the Energy Manufacturing Company, Philadelphia, Pa., which

is specially designed to work in hatchways for raising and lowering goods from floor to floor. This contrivance appears to meet the demand for a cheap hoisting arrangement in places where limited space or the heavy initial outlay forbids the use of more complicated elevators. The gearing is arranged in a cast iron frame bolted to the ceiling, and an automatic brake is provided, by means of which the load may be held at any required height, and the rate of lowering the same regulated to suit requirements. The hoist can be easily worked by one man. The advantages claimed are: that the hoist is very compact, its length not exceeding 22in.; that the parts subject to wear may be easily replaced, and that the rope cannot slip or leave the wheels. The hoists are at present constructed in two sizes, for raising loads of 500lb. and 1000lb.

PONTOON AND FLOATING DOCKS.*

In this paper, any floating structure having open ends, and sides of equal and uniform section throughout, by which ships are lifted out of the water, will be called a "floating dock;" but structures having sides varying in height and of less displacement than the bottom tanks will be called "pontoon docks." The sides are supposed to commence at and rise above the deck. The deck is the platform on which the keel blocks rest. In designing an open ended floating or pontoon dock to lift a ship of given maximum size and weight it is necessary: (1) For the under deck displacement of the dock to be greater than the combined weight of ship and dock; (2) the dock should be sufficiently strong not only to support the intended maximum ship, but so strong that it will not be injured if the ship has been built or damaged in such a way that a great part of the ship's weight rests either amidships or at the ends; (3) the sides should be made as low and narrow as efficiency will permit, so that a wide working platform may be secured and light and air have access to the ship, and that the top weight and displacement be a minimum; (4) the water should only have a limited cross range in the tanks; (5) if the dock is emptied by pumps, the pumps should be close to the bottom of the dock, so that the water may as far as possible run into the pumps without having to be drawn in. The pontoon built under the writer's Letters Patent for the Tyne Pontoons and Dry Docks Company, Limited, Wallsend, fairly fulfils the above conditions. Fig. 1 is a longitudinal view of the pontoon, Fig. 2 is a plan, Fig. 3 is a half midship section and half cross section through sill, showing the keel blocks supported on three longitudinal girders G, F, and G¹. These girders are stiffened by intercostal plates A on every third frame. Stanchions are fitted to the intermediate frames. The frames throughout are 31in. from centre to centre. The transverse gusset plates in tank C are on every third frame, but in tanks D and E are only on every sixth frame. The frames between the gusset plates are fitted with stanchions. The longitudinal water tight girders are shown by F, G, H, I, and K. Three transverse bulkheads divide the pontoon tanks into four longitudinal parts, as shown on the plan (Fig. 2), forming altogether twenty-eight separate tanks. The plan also shows that the main tanks terminate some distance within the ends and sides of the pontoon. This arrangement permits of an all round internal examination and free communication between the two engine rooms when the pontoon is sunk. The outside shell plates, up to and a little above the tank top, are $\frac{7}{16}$in. thick. They and the tank top plates are double riveted in seams and butts throughout. Two centrifugal pumps, engines, and boilers are placed in the forward end. The pumps are placed, and draw from the main cross drain M (Fig. 2), which forms part of the structure, and is in communication with the various tanks adjoining. The pumps appear to be well placed, for they have pumped freely. There is a sluice valve in the cross drain in the longitudinal centre line, so that usually the port pump only pumps from the port tanks, and the starboard pump from the starboard tanks. Before sinking the dock the distributing valves shown on Fig. 2 are opened, and remain open until the dock is completely raised again. In fact, it would be better not to have these distributing valves, but to draw direct from the end of each tank, and thus each longitudinal set of tanks would be entirely independent of its neighbours. The water coming in or going out is entirely controlled by the admission or exclusion of air from the various tanks; *i.e.*, if in lifting the dock it was considered necessary to keep the water in any particular tank, the air pipe for that tank would be kept shut, and this gives the necessary control over the water. The pumps are run full speed during the lifting of a ship, and the man in charge is on the dock or ship, and controls the air pipes, as above described. There are two donkey pumps and a range of piping, by which the tanks can be drained or the dock washed, or ships supplied with water to test tanks, fill boilers, &c. The pontoon was successfully launched, broadside on, in a nearly finished condition, into a space little wider than twice its breadth. The launching ways were an arc of a circle. A ship was docked and lifted within a week after the launch. It has been in constant use for three years, and has lifted 170 steamers in that time. The largest ship lifted measured 300ft. long, 37·3ft. beam, and 27·3ft. depth of hold to upper deck; the ship overhung the pontoon 25ft. at one end and 15ft. at the other. A ship carrying 1000 tons can be lifted and sighted in about an hour. To show its adaptability, and the ease with which it can be worked, it may be stated that a steamer was undocked and the pontoon lifted, and all the keel blocks moved and set in two rows to suit a centre ladder steam hopper dredger, and again sunk and the dredger lifted, all in one tide. The pontoon is lighted by gas throughout. Some such reasoning as the following led to the sides being made in form as shown by Fig. 1. A ship to be moved into a dry dock or on to a slip must have sufficient stability in herself, or ballast must be added to give the necessary stability before she can be moved; therefore, in this condition she requires no external aid. A pontoon when sunk, ready to receive a ship, must, in virtue of its construction, have the combined centre of gravity of the structure and contained water some distance below its centre of buoyancy, and consequently it must remain upright, even if totally submerged. Now, as it has been shown that the ship must be stable, and the pontoon has enormous stability, it is evident the pontoon requires no sides above the water to give it stability at the time when it and the ship are combined; but while the water is being pumped out of the pontoon, the combined centre of gravity of the ship, pontoon, and its contained water, will rise, and the combined centre of buoyancy will fall; and, therefore, the dock must have sides to give stability as it rises, until ultimately the sides are made the full length, and the maximum stability is secured with a minimum of top weight and displacement. The sides, being low, allow light and air free access to the ship, and the ship's bottom is thus easily seen and rapidly dried.

Fig. 4 is a cross section of the Rotterdam Harbour Authority's two floating docks. They have been in use about four and a half years, the work upon them is excellent, and I believe the docks are strong. Fig. 5 is a cross section of a dock built, or building, by the Dutch Government for the East Indies. It appears to be exceptionally strong. Figs. 6 and 7 show a design the writer proposes to employ for making a self docking pontoon where desirable. It will be noticed that the centre part can be taken out and lifted by the two side pieces, as shown on Fig. 6, *b*; or one side can be lifted by the centre and one side piece, as on Fig. 6, *a*. This plan has many advantages, the longitudinal strength of a solid dock is maintained, and its cross strength is easily provided for. The design is convenient for transport, or for placing in ordinary dry or wet docks. The writer is quite sure the connections of the three parts can be arranged to be thrown adrift, and one part lifted by the other two in one tide. It would be interesting to compare in detail these docks, both in strength and stability; but this of course cannot be done here. The lifting power of the various docks may be taken to vary roughly as the under deck displacement. Sir Frederick Bramwell, in his paper on "Floating Docks," read before the Institution of Mechanical Engineers in 1867, pointed out that their stability varied as the square of the number of tanks in the cross section of the dock. If this is true, then all floating docks should be built with numerous water tight longitudinal bulkheads, so that the water may have comparatively little transverse motion. Figs. 8, 9, and 10 illustrate the above. Fig. 8 shows a dock and ship listed to 5°. The water is allowed to travel from side to side. The positions of the centre of gravity and centre of buoyancy show the dock to be unstable, and that it will go further over before coming to rest. The same applies to Fig. 9, only in a less degree, as the water can only travel between the centre and the side. Fig. 10 shows the dock and centre of buoyancy in the same position as Figs. 8 and 9; but the centre of gravity is on the stable side, and if any internal or external force was able to list the dock so far over, it would right itself. The relative initial stability of the three docks, exclusive of the ships' stability, and purely because of their internal construction, would therefore be 1, 14, and 49. In 1869, Mr. G. B. Rennie read a paper before the Institution of Naval Architects, in which he describes the Carthagena floating dock, and gave its righting moment at 10° list when the dock is out of the water, and at the same time supporting a Spanish war vessel. This, of course, is a most stable condition for the dock when supporting the steamer. As far as the writer can learn from the paper, he does not take into account the effect of the contained water travelling over as the dock lists.

The diagram he gives is purely one point in the metacentric diagram. This seems to be the usual way of showing a floating dock's stability, but it is, in my opinion, extremely misleading. The metacentric curve for docks is only useful as a means of comparison when the docks are of similar design and uniformly proportioned. I will endeavour to explain this fully from calculations made for a pontoon dock which has not yet been built, so that no one can object to their publication, and it will be called the model pontoon. Let the displacement curve D, on Fig. 11, represent the pontoon's displacement curve, M its metacentric curve, and B its centre of buoyancy curve. Fig. 11 also shows the displacement *d*, centre of buoyancy curve *b*, and metacentric curve *m*, of a deep, narrow, tender proportioned steamer, which is supposed to be the heaviest ship this particular dock will lift. The figure also shows the before mentioned curves combined in M^2 B^2, and also the combined centre of gravity curve G^2, as if the vessel and pontoon were one structure, and to be raised as one. In making such calculations, it is necessary to be perfectly sure that, if there is an error, it shall be on the safe side; and having this in view, the steamer's centre of gravity is supposed to coincide with its light draught metacentre G on diagram 11; and we may take it that the steamer could not be moved into the dock if the centre of gravity had been higher. The centre of gravity of the pontoon is supposed to coincide with its centre of total displacement. This is also well on the safe side (Mr. G. B. Rennie places the centre of gravity of the Carthagena dock one-fourth lower). The centre of gravity of the water in the tanks is supposed to remain constantly at half the height of the bottom or under deck tanks. It is possible, under extraordinary circumstances, that the water might remain so high; but it is not possible for it to be higher. Along with this explanation, it is necessary to say the calculations have been carefully made on the actual form of a ship and the model pontoon, having tanks arranged as shown in Fig. 10. You will notice the result shown by Fig. 11 is, that at a pontoon draught of 23ft., there is 4½ft. metacentric height, with the combined centre of gravity 18in. above the combined centre of buoyancy. And at a draught of 17½ft. we have the least metacentric height, viz., 3¼ft. when the combined centre of gravity is 6ft. above the combined centre of buoyancy. At 11ft. draught, when only the keel of the ship is in the water, we have 9ft. metacentric height with the combined centre of gravity nearly 12ft. above the combined centre of buoyancy. And at 7ft. draught we have 33ft. metacentric height when the combined centre of gravity is 14½ft. above the combined centre of buoyancy.

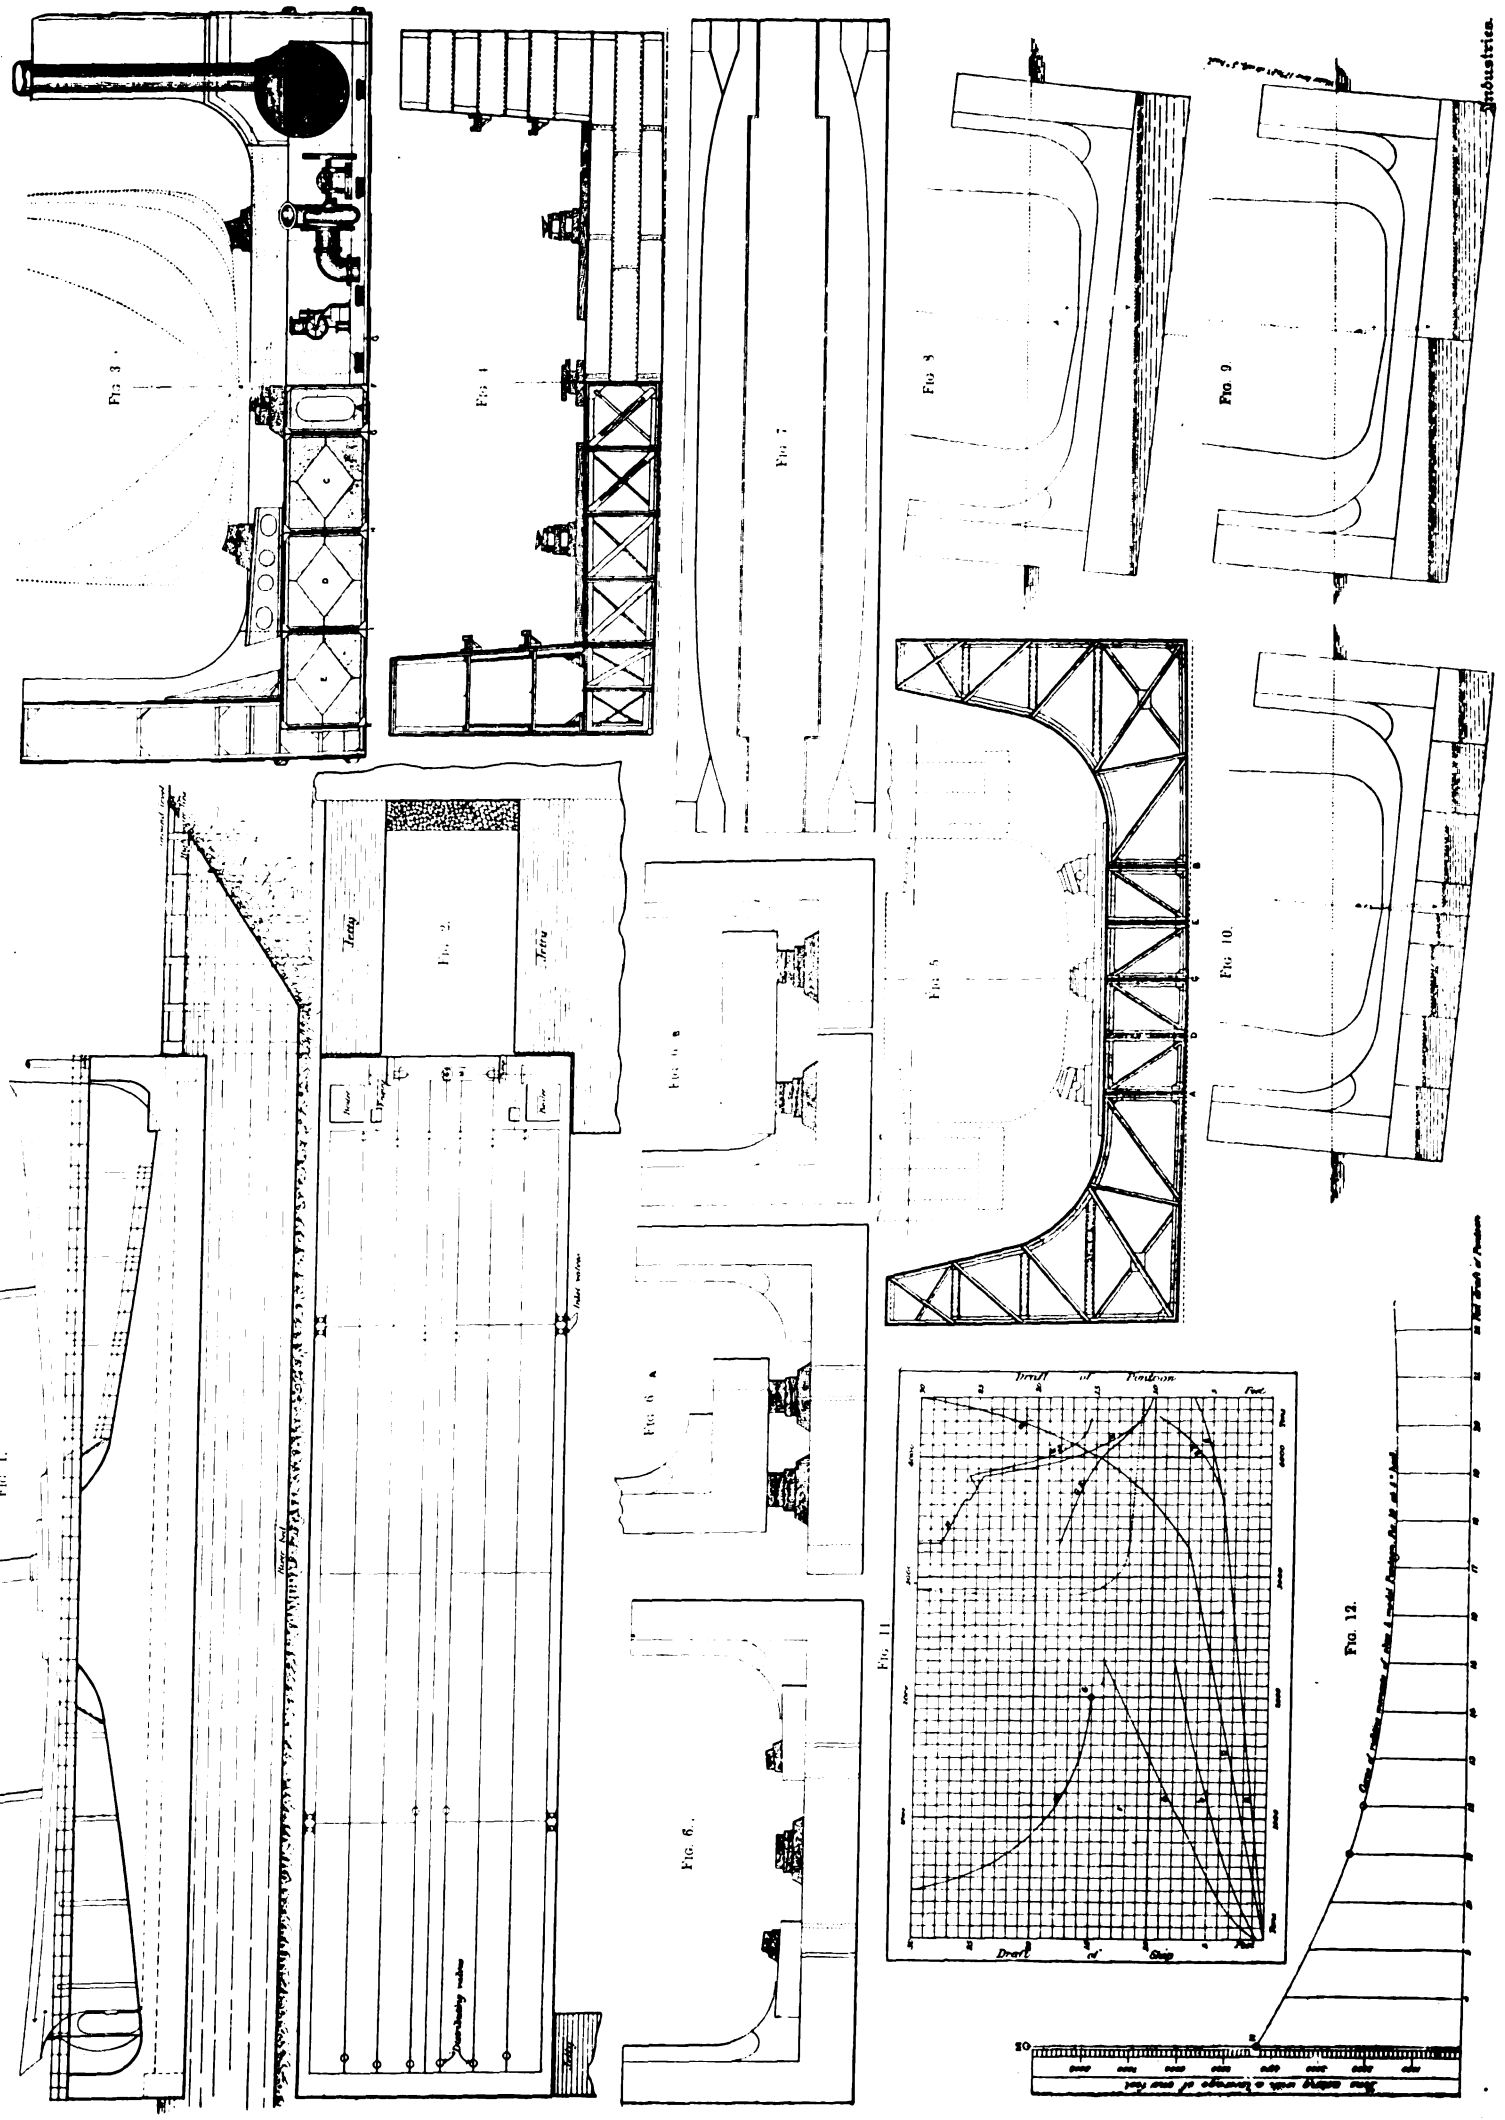


Diagram 12 shows the combined righting moment for the said ship and pontoon at 5° list during the whole process of lifting the vessel, from the time the ship touches the blocks to the time the dock is pumped dry. Where the curve of moments runs into the vertical ordinate at N, representing 7ft. draught, the righting moment is calculated for the water being over one-half the pontoon deck, while the moment M on the same ordinate is calculated for the deck entirely free from water, in which position the dock invariably is when supporting a ship out of water. Of course it must be clearly understood that these diagrams, &c., give the model dock's stability under the most unfavourable conditions possible to conceive.

* Paper read by Mr. Alexander Taylor, before the North-east Coast Institution of Engineers and Shipbuilders, on the 11th April, 1888.

FOREIGN INDUSTRIES.

(From our own Correspondents.)

PARIS, 22ND MAY, 1888.

THE IRON MARKET.—The issue of circulars by the Paris iron merchants announcing an advance in prices is beginning to be looked upon as a farce; but in whose interests or for whose entertainment the farce is played does not appear. I announced a fresh issue last week, and I have now to report the fact that though the official quotations are thereby raised, buying and selling goes on under former conditions. Thus no progress has been made, and the situation has rather been weakened by the declaration of a rise which cannot be maintained. This state of things appears to be the result of efforts on the part of the merchants to render themselves independent of the manufacturers of the North by buying in other markets. How long this will last depends on the progress made in syndicating the trade. A perfect understanding has been come to between the manufacturers of the North and those of the Centre. If the agreement be extended to the Eastern departments, the merchants will find themselves isolated, and this is likely to happen. I quote these facts to show, first, that the ordinary newspaper reports do not accurately represent the state of the Paris markets; and second, that the true state of the latter is not typical of the iron trade generally. Business in the provinces is being transacted on a firmer basis, and there is no "cutting" trade being carried on. The demand is fairly active all round, and sellers neither offer nor grant concessions. That prices are more likely to advance than to recede may be judged from the fact that the time is at hand when manufacturers of finished iron and steel will have to renew their contracts for pig, and at current rates these contracts would be considerably above those on which they are now working. It is announced that the Danish naval authorities have decided, as the result of a series of comparative experiments, to use Creusot steel plates for the armour of the new cruiser "Walkyrie." This is considered another triumph for French industry.

THE METAL MARKET.—The copper market is still firmly upheld by the syndicate notwithstanding the constant accumulation of stocks or the prospect of a further restriction of the consumption in consequence of the abnormally high prices now prevailing. Meanwhile, production is steadily if not rapidly increasing. The collapse may yet be distant; but when it comes it will be, like that in tin, sudden and complete. Tin has further receded, and is now quoted at £100 a ton—a fair price, below which it is not likely to drop. Lead is being pressed for sale; the price has dropped slightly since the beginning of the week, and is likely to go lower, production being in excess of consumption. Spelter continues its retrograde movement.

STRIKE IN THE GLASS TRADE.—The strike in the glass works of the Seine and Seine-et-Oise, by which about 2500 hands are thrown out of work, continues. The dispute arose from an attempt on the part of the trades union, or what is here the equivalent of an English trades union, to force their will upon the masters in the matter of dismissing one of their managing clerks. The masters seem to be determined to resist this encroachment on their rights. On the other side the men are encouraged to persevere in their attempt by the sympathy and material aid of the municipal authorities of Paris, who have voted £400 for the relief of the men on strike. The works effected are for the better class of glass goods. The agents of Belgian and German firms are endeavouring to turn the opportunity to account.

TELEPHONIC EXPERIMENTS.—Last week an attempt was made to communicate by telephone with Marseilles from Dijon, a distance of 480 miles. The experiment was entirely successful. A further trial to extend the communication to Troyes, a distance of some 600 miles from Marseilles, was but partially successful, owing, it is said, to defects in the line from Marseilles to Troyes. As soon as these defects have been remedied the trial will be repeated.

BERLIN, 21ST MAY, 1888.

THE IRON MARKET.—On the whole the condition of the iron trade has been satisfactory during the past week. In the Upper Silesian district there are at present twenty-seven blast furnaces in action, and prices rule as follow: Forge pig, 50s.; and foundry pig, 58s. to 60s. The demand for foundry pig is at the present moment on the increase, as iron founders and engineering works are well supplied with orders, and in some cases even work overtime. Business in rolled iron has remained normal. The question of the supply of steel rails to the Bromberg railway adminstration is at present exciting the attention of rail makers. The administration not wishing to pay the high prices imposed by the syndicate, have approached them with a request to reduce their prices; but the negotiations have not yet had the desired result. If the syndicate will make reductions, the order will probably go to the Bochum Works for 3200 tons, and to two Silesian works for 1600 tons each. German steel rail makers are, however, afraid that they will lose these contracts, on account of the low offers received from England.

UTILISATION OF BLAST FURNACE SLAG.—Herr G. Hoffmann has, in conjunction with the Tarnowitz iron works, introduced the manufacture of artificial stones, flags, stair treads, &c., for which purpose the slag from the blast furnace is utilised. This industry, which has now been established for some time, has been so successful that depôts for the sale of these artificial stones have been opened in various towns of Upper Silesia. Herr Hoffmann has agreed with the Tarnowitz works to take all the slag he requires from them, to the exclusion of any other works; and as the stocks of slag on hand amount to about 500,000 tons, there will be no lack of raw material for this industry for many years to come. In addition to the price paid for the slag, Herr Hoffmann pays to the works a yearly rent of £750 for permission to carry on his manufacture on the premises.

INDUSTRIAL IMPORTANCE OF INLAND WATER WAYS.—Herr Natorp, who represents the coal mining interests, in a speech made last week in the Landtag, in support of a measure for the improvement and extension of the inland water ways in Germany, said: "If the projects for canalising the Oder and deepening the Spree be carried into effect, a new district will be opened up to the manufacturers and other producers of Upper Silesia. Coal may then be sent to Stettin at a low cost, and German colliery owners will be enabled to gradually drive back British coal from those districts of North Germany where hitherto we have failed, in consequence of the cost of railway carriage, to do more than gain an insecure foothold."

CENTRAL STATION LIGHTING.—The Town Council of Hamburg are erecting an electric light central station, independently of the installation on the bonded warehouses which you recently described. The capacity of the station is to be for 10,000 lamps at present, but with provision to increase it to 20,000 lamps next year. The generating plant will be erected on the site of the old and disused town mill, and a district of 13,000ft. radius is to be supplied. The glow lamps will be of 16 c.p., and the arc lamps of 8 ampères. The cables are designed to carry 20 per cent. more current than corresponds to the 10,000 16 c.p. lamps, and in December next a portion of this installation is to be in working order. Of the ten boilers projected, six are already installed, each with 2700 sq. ft. heating surface, and working at a pressure of 100lb. The grates are arranged for coke firing, and there are two chimneys each 130ft. high. Motive power will be supplied by four steam engines of together 1100 h.p., viz.: One of 100 h.p., one of 200 h.p., and two of 400 h.p. There will be six dynamos, one of 1000 and five of 2000 lights capacity. For street lighting there will be fixed sixty-four arc lamps, each of 8 ampères. The loss of pressure in the feeders is estimated at 13 per cent., and in the network mains at 1·3 per cent.—The Helios Company of Cologne are erecting in Amsterdam a central station for an output of 2000 ampères at 65 volts. The cables are designed for a loss of 2 per cent. only. Current will be supplied by two steam dynamos, each driven by a twin engine, the fly wheel of which carries the armature. A central station with storage batteries has been projected for Barmen. The distribution is to be on the three-wire system from four parallel series of Tudor accumulators, each series containing 136 cells. The accumulators are to be charged in parallel by five shunt dynamos working at 250 volts.

VIENNA, 21ST MAY, 1888.

THE IRON MARKET.—Business in most branches of the iron trade has remained normal during last week. Crude iron is now firmer than it was during the winter, and the demand for forge pig is on the increase. Bar iron and sheets continue fairly active, but in tinned sheets a fall in price is expected, owing to the drop in tin. Engineering works, with few exceptions, are well supplied with orders. The Austrian State Railway administration recently invited nineteen Austrian firms to tender for plant required for the water supply on some new lines now in course of construction. The successful tenderers were E. Skoda, of Pilsen, Bohemia, for seven complete plants for water supply, including boilers, engines, pumps, piping, and reservoirs, and an engineering works in Prague for five plants for water supply, and five locomotive turntables. Messrs. L. Lang, of Buda-Pesth, have just booked an order for a 420 h.p. triple expansion engine, for a large jute spinning and weaving mill in the same town. This engine will work with a pressure of 160lb. per sq. in. They have also in hand a 450 h.p. engine for the new small arms factory, and a 600 h.p. rolling mill engine for the Rima iron works. In the engineering works of the Austro-Hungarian State Railway, there was completed at the beginning of this month the two thousandth locomotive, an event which was celebrated by some festivities. This locomotive is an express engine, intended for the Sicilian railways. Out of a total of 2000 engines built by the works up to the present time, 1640 have been supplied to railways within the Empire, and 360 to foreign lines.

THE JUBILEE EXHIBITION.—Although this Exhibition, which was opened on the 14th inst., has been organised by the Niederoesterreichische Gewerbeverein, that is to say by a society distinctly local to Lower Austria, considerable support has been received from other parts of the Empire, and the list of exhibitors includes nearly all the important manufacturers in the various Austrian provinces, and even Hungary is represented to a certain extent. The exhibits are divided into twenty-one groups, of which I only mention a few as likely to be interesting to your readers: I., Mining and metallurgy; II., Chemical industries; IV., Leather and india-rubber; V., Textiles; VII., Wood work; VIII., Paper; XII., Engineering and means of communication; XIII., Electrotechnic; XIX., Civil engineering and architecture; and XX., Safety appliances.

TEXTILES.—Since my last report the situation in cotton has improved considerably, both as regards volume of trade and prices. In linen goods, however, there has been no change. The greatest activity in the textile industries is displayed in the north-west of Bohemia, where the present tendency is to increase works and manufacture on a large scale. Textile industries are also well developed in the Reichenberg district, where it was shown in a recent census that out of a total of 4278 industrial establishments, the majority are textile factories. The total number of steam engines required for industrial purposes throughout the district is 1736, representing a total of 46,897 h.p., whilst there are in addition 3115 water motors representing 28,048 h.p. The total number of hands employed is 147,378.

ELECTRIC LIGHTING OF THE JUBILEE EXHIBITION.—The steam and dynamo plant for the lighting of this Exhibition is as follow: There are fifteen boilers having an aggregate of 16,000 sq. ft. heating surface. The boilers are divided into three groups. The first, representing about 8500 sq. ft. heating surface, is required for the lighting of the Rotunda and adjoining galleries; the second of 6000 sq. ft. for the external lighting and that of the machinery hall; whilst the third will be required for the lighting of various annexes. The boilers are of different types, but all work at a pressure of 105lb. per square inch, the feed water being supplied by the high pressure town mains. The first group of boilers supplies in all seven steam engines of an aggregate of 800 h.p. Of these there are three compound engines, of 200 h.p., 200 h.p., and 120 h.p. respectively; two single cylinder engines of 100 h.p. and 170 h.p. respectively; and two high speed engines of 60 h.p. and 50 h.p. respectively. There is also one vertical engine of 60 h.p. of the ship lighting type, and a vertical engine and boiler, semi-portable, for driving a dynamo supplying two arc lamps of 25 ampères each. The boilers of the second and third groups supply four steam engines of together 500 h.p., one high speed engine of 50 h.p., and one Colman engine of 80 h.p., also two ship lighting engines. There are the following dynamos: Five Gülcher machines for combined arc and incandescent lighting, five Krizik machines, four of which are for arc lights and one for three hundred incandescent lamps; eight Ganz dynamos, of which six are for arc lighting and two for incandescent lighting; three dynamos of Egger & Co., of which two are for arc lighting and one for incandescent lighting; four dynamos of Kremenezky, Meyer, & Co., of which two are for arc lights and two for incandescent lights; four dynamos of Siemens & Halske, of which two are for arc lighting and two for incandescent lighting; and six Edison-Hopkinson dynamos built by Messrs. Siemens and Halske. With the exception of the three ship lighting dynamos, all the machines are driven by belting from counter shafts.

BRUSSELS, 22ND MAY, 1888.

THE COAL MARKET.—The situation of the coal market at the present moment is very favourable, and a rise of about 3d. a ton has taken place in all qualities of coal. The Strepy-Bracquegnies Colliery has sold 200 tons of coke for export at 13s. 5d. A contract will shortly be made on the Brussels Exchange for the supply of 2000 tons of coal for the State railways. The imports during the first three months of the present year were as follow, the quantities being given in tons:—

	Coal.	Coke.
Germany	93,783	3220
England	59,772	1028
France	38,813	832
Holland	36,539	1294
Other countries	60	—
Total	228,967	6374

The exports during the same period were:—

	Coal.	Coke.
France	902,317	201,118
Luxembourg	24,191	44,364
Holland	36,205	—
Other countries	23,612	6,311
Total	986,325	251,793

There has been a considerable diminution in the imports of coal; but, on the other hand, those of coke have increased. As regards the exports, coal shows a falling off as compared with the same period of 1887, whilst coke shows an increase. In addition to the exports given above, there were exported 72,562 tons of briquettes. The quantity of coal at present carried on the Belgian State railways is greatly in excess of that transported at this time last year.

THE ENGLISH SECTION AT THE BRUSSELS EXHIBITION.—The efforts put forth by Mr. S. Lee Bapty to push on his portion of the Exhibition have been so successful that the British section was opened to the public on Saturday last. Lord Vivian, the English minister, the Comte d'Oultremont, the Commissioner General of the Belgian Government, and M. Somzee, the president of the Exhibition, took part in the proceedings. A very good representative display of English manufactures is made, this being the most important of the foreign sections of the Exhibition.

THE METAL MARKET.—Many iron masters are of opinion that in view of the scarcity of pig and the rise in the price of coal, the base price of merchant iron for home consumption should be advanced. Forged iron is in good demand, and engineering establishments are receiving larger orders.

Digitized by Google

La Metallurgique works have obtained the order for the iron work for the covered market at Buenos Ayres. Contracts will be made to-morrow for the supply of sixty-three 5-ton coal waggons for the State railways. Two lots, each for fourteen complete engine tenders, will also be contracted for shortly. The Esperance works of Liège intend to start a second blast furnace at their Seraing works in addition to that which I mentioned in my last letter. The imports and exports of iron and steel during the first quarter of this year were as follow, the quantities being given in tons:—

	Imports.	Exports.
Steel ingots	424	2413
Steel rails	88	10,154
Other rolled steel	683	7508
Pig iron	52,734	3185
Old iron	5769	268
Iron wire	922	1009
Iron rails	68	3170
Sheets	450	9837
Other rolled iron	1833	47,926
Nails	135	2629
Wrought iron	948	4722
Malleable castings	172	2938
Wrought steel	67	516

The imports of pig show an increase of 24,518 tons as compared with the same quarter of last year. The principal event during the past week has been the opening of the tenders for the supply of 8000 tons of Goliath rails for the State railways. The Cockerill Company tendered for 3400 tons, the Ougrée works for 2200 tons, and the Angleur works for 2400 tons, all at 91s. 8d. per ton, these three firms having formed a ring; G. Boël for 1500 tons at 95s.; the Acieries de France for 6000 tons at 93s. 6d., and for 2000 tons at 87s. 7d.; and Caramin & Cie. for 4000 tons at 94s. 5d. It will be seen from the above that the average Belgian price was lower than that of the French company.

Electric Lighting at the Exhibition.—Contracts have at last been signed with the firms who are to undertake the electric lighting of this Exhibition, and these companies can now commence operations. As I have already stated, the original scheme has been greatly modified, and the lighting of the buildings and annexes has been given to the following seven firms: The Thomson-Houston Co.; La Société Industrielle; Messrs. Bouckaert and Cie.; La Compagnie Electrique; M. Dulait; M. Khotinsky; and Herr Zipernowsky. The Thomson-Houston Co. will supply seventy-six arc lamps of ten ampères, of which twenty-four will be in the machinery department, eighteen in the foreign annexes, twenty in the horseshoe building, six in front of the main buildings, and eight in the central pavilion. La Société Industrielle will furnish fifty seven-ampère arc lamps, thirty of which will be placed in the Salle des Fêtes, and twenty in the working breweries. Messrs. Bouckaert & Cie. will supply sixty arc lamps of eight-sixteen ampères, fourteen of which (ten ampères) will be in the machinery department, eighteen in the Belgian section, and the remainder in the restaurants of Mr. Mackenzie Ross. La Compagnie Electrique will furnish twenty-two twelve-ampère arc lamps for the machinery department and seventy-five glow lamps. M. Khotinsky will provide 250 glow lamps, which will be fed from accumulators, and Herr Zipernowsky will supply 200 glow lamps. Special contracts have been made with the Anglo-American Brush Corporation for forty arc lamps of ten ampères, and with M. Pieper for the same number, for lighting the gardens. It will be seen that the larger share of the electric lighting has fallen to foreign firms.

DÜSSELDORF, 21st May, 1888.

The Iron Market.—The general aspect of the iron market is, on the whole, satisfactory. There is a lack of activity in some classes of goods, notably in bars, sheets, and wire; but in others there is a strong and steady current of business. The improved state of the Belgian and French markets has had a strengthening influence here. The supply of ore to the blast furnaces is now scarcely equal to the demand, and high prices have in consequence to be paid for immediate delivery. This fact, and the scarcity of coke, points to the maintenance of the current rates for pig iron for some time to come. The crude iron market remains unaltered since last week, the demand for home consumption continuing brisk, while the export business grows more and more languid. The export market has been unfavourably influenced this week by the announcement of the abolition, from July 1st next, of the special export tariffs for pig iron from Dutch ports. The latest Cologne prices are: Spiegel of 10 to 12 per cent., 59s. to 60s.; German Bessemer pig, 54s. to 55s.; white forge pig, 51s. to 52s.; Luxemburg white forge, 38s. 6d. to 40s.; and German foundry, No. 1, 57s. 6d. a ton. The tone of the finished iron market has become more confident since the announcement, a few days ago, of an agreement formally entered into between the German finished iron syndicate and the Austrian iron syndicate, with a view to prevent excessive competition in the frontier districts. The home demand for bars has become slack again except in a few localities, and foreign business is almost at a standstill. The activity is now chiefly in plates. Sheets are neglected, and manufacturers have begun, in some instances, to work for stock. Hoop iron is quiet, and wire remains very dull. The wire nail syndicate lately established seems to be on the point of collapsing, in consequence of the evident gravitation of the trade towards those makers who have remained outside the association.

The Tin Plate Trade.—The manufacture of tin plates in Germany, though not yet one of great magnitude, is steadily growing in importance. The production amounted in 1883 to 11,238 tons; since that year it has increased as follows: 12,149 tons in 1884, 11,786 tons in 1885 (a falling off from the previous year), 13,570 tons in 1886, and 17,808 tons in 1887. The net imports in the last named year amounted to 20,808 tons, against 32,901 tons in 1886. Nearly the whole of the tin plates imported are derived from England. The constant growth of the native industry points to the annihilation of this import trade. The greater consumption now going on has, however, occasioned heavier purchases of English tin plates in the first quarter of the current year, the total net imports of that period being 7501 tons, against 6170 tons in the corresponding quarter of 1886.

Chain Testing Works at Lübeck.—There will shortly be established at Lübeck complete and very important works for testing chains. The design originated with Herr von Baggessen, the proprietor of testing works at Hamburg, and is being carried out by him in conjunction with several influential commercial men connected with the shipping trade. These works, the first of the kind in Germany, are likely to operate beneficially to the Westphalian iron and engineering industries, by causing much of the trade which now goes to England to be transferred to them. At present the German ship owners get practically all their chains and anchors from England, the reason given being that they prefer goods of English make, because hitherto there have been no means of testing these chains in Germany. As this want is now on the point of being supplied, an effort will be made by the Westphalian chain makers to induce ship owners to buy in the home market. The scheme provides that manufacturers shall send the goods to Lübeck to be tested, and there stored till sold, so that the purchaser who obtains his chains from the Lübeck store will have a guarantee of their having been properly tested.

LILLE, 22nd May, 1888.

Textile Manufactures.—As the weeks roll on it becomes more and more certain that the hopes freely indulged in at the beginning of the year, that we were entering on a period of life and activity in the textile trades, are doomed to be disappointed. Business is everywhere languid and declining, and the prospect affords but little ground for encouragement, owing to the insecurity of the political situation. No one has any confidence in the permanency of existing institutions, and there exists that vague, indefinable fear which, more than a certain knowledge of imminent and clearly perceivable danger, stifles the spirit of enterprise, and keeps all commercial transactions within the narrowest possible limits. Until we have a strong and settled Government, we shall look in vain for commercial activity. This week the market reports from all our great centres of the textile goods trade are characterised by a gloomy tone. Business is becoming more and more restricted. Nowhere is there anything approaching to healthy, vigorous life, and, what is more discouraging, there are no symptoms of improvement.

Flax and Yarn Markets.—A little more has been done this week in home grown flax at firm prices. In Russian, business is at a standstill. Yarns, too, are quiet. Consumers have now considerable stocks in hand or contracted for, and as the woven goods trade is slack, they are unwilling to commit themselves further. The Ghent markets are dull both for raw flax and for yarns.

The Iron Market.—There is no new feature in the iron market calling for special notice. Business is fairly active in all the principal classes of iron goods, and prices are very firm. It is worthy of notice, as bearing on the question of prices, that the coal owners in renewing their contracts with the iron masters stipulate for an advance of 1fr. a ton for all coal and coke delivered in the next three months, and 2fr. a ton for all deliveries of a later date.

WINTERTHUR, 21st May, 1888.

Textiles.—Constant complaints are made as to the depressed condition of the cotton spinning trade, and only those mills which are favourably situated and which have the most improved machinery are able to work at a profit. No one is inclined to take the initiative in reducing the production. The contrary is the case, for manufacturers are endeavouring to reduce the proportion of their permanent expenses by increasing the output of the machines. Self acting spindles which were formerly run at 6000 revolutions per minute are now being worked at from 8000 to 9000 revolutions, and so on. The workpeople employed in the industry are paid according to the quantity of work turned out, and the earnings of spinners now average 3s. 6d. to 3s. 8d., and those of flyer hands from 2s. 2d. to 2s. 7d. The fine weaving and newly introduced tulle industries are in a very unsatisfactory condition. Many looms are standing, and weavers earn only 1s. 8d. per day. The weaving of coloured goods is even in a worse condition, as printed cotton goods are supplanting this branch of manufacture. The earnings of weavers seldom reach 1s. 8d. per day. The condition of the silk trade is, however, more favourable. Some of the silk weaving mills are being enlarged, and dye works are well supplied with orders. The continual complaints regarding the low wages ruling in the silk trades have induced the Government Inspector of Factories to collect statistics, from which it appears that, in large factories, the average fortnightly earnings of weavers are 26s. 6d., and of warpers 25s. In smaller factories the wages are somewhat lower.

MADRID, 21st May, 1888.

Almaden Quicksilver Mines.—A rumour is current that the Government is thinking of selling these mines, or that some influential persons are desirous of acquiring them. This belief has been caused by the fact that changes have been made in the administration of the mines which are not justified either by their technical or economical requirements.

Wood Pavement.—A contract has been made by the municipal authorities for paving the principal streets of Madrid with wood. This system of paving has already been found to work well at Bilbao.

Electric Lighting of Theatres.—The first theatre in Madrid which has complied with the new regulations enforcing the exclusive use of the electric light in theatres is La Comedia Theatre, a very well appointed and fashionable house of medium size. The installation consists of a Collet tubular boiler, a Daevel vertical high speed engine, and two Schuckert's dynamos of 75 ampères and 105 volts. There are fitted 450 glow lamps, made by Messrs. Siemens and Halske, of Berlin.

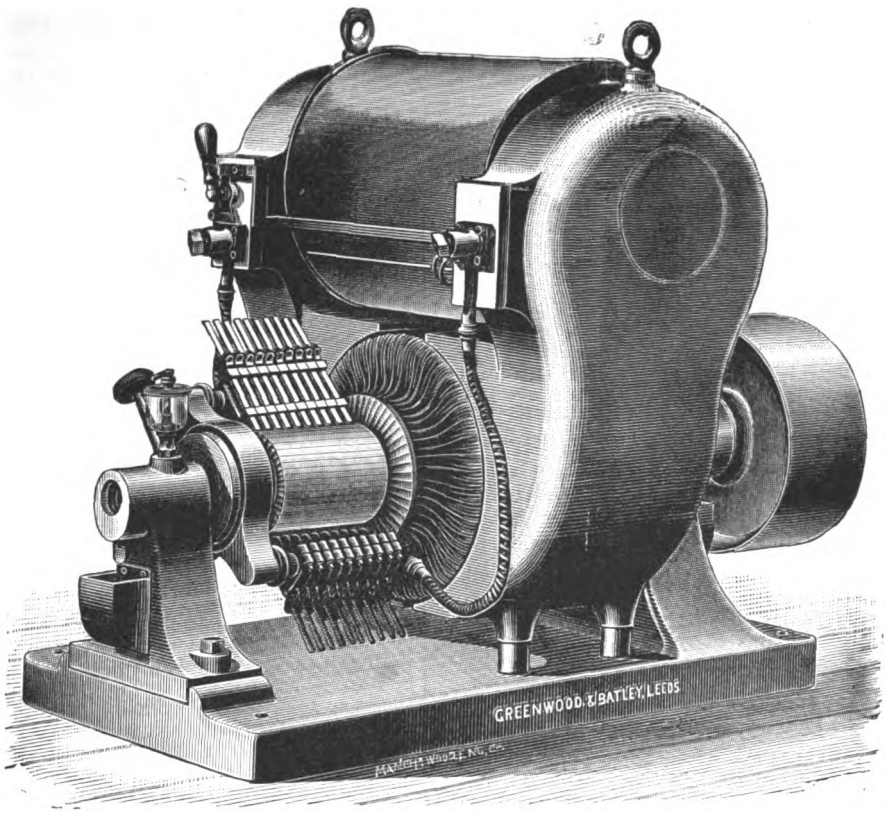
NEW YORK, 12th May, 1888.

The Coal Market.—There is now a better feeling in the anthracite coal trade, and dealers report an increased demand. Production has decreased. Bituminous coal is considered to have touched bottom, and a better demand with higher prices is expected.

The Iron and Steel Market.—The pig iron market has shown a fair degree of activity during the past week, with a little weakening in prices of the better qualities. Consumers are not willing to pay over $20·50 per ton for the very best brands of No. 1 foundry, and $16·50 for grey forge. Buyers do not care to take more than a few weeks' supply. In the lower grades, prices are steadier, as the parcels offered are light, and with anything like a fair demand it is probable that prices would advance. There is great dulness in manufactured iron; the demand is small, and the prices ruinously low. The worst competition comes from the Carnegie Mills, Pittsburg, and other Western Pennsylvania firms. Their policy is to run full, and as they have a line of specialties which yield a good profit, these are made to pay for losses elsewhere. Prices are irregular, but average about 1·85c. and 1·9c. per lb. for best refined bars, 2c. and 2·15c. for angles and plates, and 3·3c. for beams and channels. Steel rails are extremely dull, with prices at $31·50 and $32 per ton at mill. Western advices are not encouraging, and buyers are in no hurry to place orders. There is, however, no cutting, and prices may remain as they now are for some time to come.

The Metal Market.—The copper market has been well sustained, and business has been done at about 16·70 cents per lb. The collapse of the tin corner has had no influence on the price of copper, but has slightly affected the volume of business. There have been no failures in connection with the fall in tin, although some of the operators are badly crippled. As the market is now down to consumers, prices there have been numerous inquiries, with indications of a fair amount of business in the near future. Tin plates have been steady, the decline in pig tin having already been discounted in the plate trade. Prices are likely to remain steady, although the market has been unsettled. Lead has been very quiet. Sales to consumers and dealers have amounted to about 400 tons, at 4·60 cents per lb. for spot. Spelter is dull, but with rather a firmer tone than it has had for some time past. Prices for common domestic range from 4·65 cents to 4·75 cents per lb.

Bridge Building.—The key plates of the great steel arch of the new Harlem Bridge at 181st-street have been swung into position, and if the work continues at the present rate it is believed that the bridge will be open for traffic in December next. There are two steel arches, each 510ft. long, and the entire length of the bridge is 2373ft. The roadway will be 50ft. wide, with 15ft. footpaths on each side, making the bridge over 80ft. wide. The arch will be 133½ft. above the river, and the roadway 151ft. The work was commenced in September, 1887, and the cost will be £520,000.



PHILADELPHIA, 12th May, 1888.

The Iron Market.—There is abundant proof that the contest between Pennsylvania irons and Southern and Western is only just beginning. The transportation companies have been called on to take their share in the reduction of prices that have been and are still being made, and if furnaces and mills cannot get their materials carried at much lower cost many will have to close. As a matter of fact, iron from Ohio is being carried direct to points in New England at lower rates of freight than are being paid from points in the Schuylkill and Lehigh Valleys. The railroads are beginning to realise the necessity of lower freights, and one road has already offered reductions of 30 per cent. as an inducement to one concern which is now idle to resume work.

Steel Gun.—The Standard Steel Company, of Chester, Pa., have cast a 6in. gun of Siemens-Martin steel, which they propose to offer to the Government for the same tests to which the gun lately cast at Pittsburg will be subjected.

THE "LEEDS" DYNAMO.

THE "LEEDS" DYNAMO.

The above illustration represents an 18 kilo-watt dynamo, of the "Leeds" type, manufactured by Messrs. Greenwood & Batley, of Leeds. The core of the field magnet is of annealed wrought iron, and is provided with soft cast iron poles. The armature is of the Gramme pattern, the core consisting of thin annealed charcoal iron discs, insulated from each other in the usual way, and the winding of a single layer of copper wire. The armature shaft is of Bessemer steel, and is supported in Babbitt metal bearings. The current is taken off by a large number of small brushes, which are self lubricating. The machine is intended for an output of 180 ampères, at a pressure of 100 volts when driven at 750 revolutions per minute. We are informed by the makers that a machine of this type has now been successfully at work for two years at the Union Oil Mills, Rotherhithe.

THE SOCIETY OF TELEGRAPH ENGINEERS AND ELECTRICIANS.

In a certain sense the meeting of this Society, held on the 17th inst., was unique. Generally speaking, the papers read and discussed at the Society of Telegraph Engineers are primarily of a scientific or technical and only secondarily of a commercial character, whilst the advertising element and personal reference have happily hitherto not been more prominent than in any of the other leading scientific societies. If the proceedings were at times somewhat dull, this was not so much the fault of the speakers as it was due to the nature of the subjects under discussion, which did not lend themselves to nor call for oratorical and histrionic displays; but, on the whole, the meetings were decorous, and yet of sufficient interest to attract large audiences. Those members who had the welfare of the Society at heart could feel when they went home from the meetings that the evening had been spent in a way creditable to the Society, and that although the amusement it provided was certainly limited, this drawback was amply compensated by the scientific and technical interest of the proceedings. To such members the meeting of the 17th inst. must have come as a revelation, and let us hasten to say a disagreeable one. There was this time a maximum of amusement, but this was not accompanied by a corresponding amount of decorum or scientific instruction. To hear one eminent electric light engineer tell an equally eminent professor that he knows nothing practically about a certain subject, or to find the carefully rehearsed and grandiloquently delivered peroration of one member received with peals of laughter by the other members may be highly amusing, but it is not the kind of thing we are used to in English scientific assemblies, nor is it the kind of thing which will improve the status of the Society of Telegraph Engineers and Electricians.

The Society has been attacked from various quarters for having issued a new set of fire rules, and at the meeting alluded to above a kind of three-cornered duel took place between the Fire Rules Committee of the Society, Mr. Heaphy, and other gentlemen interested in fire insurance offices, the general body of members taking mostly part against the committee of their own Society. This feeling of opposition is difficult to understand. By issuing a new edition of their 1882 rules, the Telegraph Engineers have done what was obviously a necessity in this age of rapid progress. Mr. Preece told the members that thousands of copies of the original rules have been sold to all parts of England, and that the demand is still maintained. Should the Society continue to supply antiquated rules, should it refuse to supply any rules at all, or should it supply rules amended in accordance with modern requirements? The Council have determined upon the latter course, which would commend itself to most business men, but when it be considered that they could only in this way prevent or restrict the indefinite multiplication of rules, that they were encouraged by several fire offices to take the lead, and that they had even the assistance and approval of Mr. Heaphy up to nearly the time of publication of the new rules, it is almost impossible to understand on what reasonable grounds the Society is now censured for the publication of these rules. It must be borne in mind that the rules are merely general recommendations, and not intended to supersede any other detailed rules which fire offices may issue.

Having made these few introductory remarks regarding the meeting on the 17th we proceed to give our report of it; but in doing so we shall omit all matters constituting the amusing and personal element, limiting ourselves to the points which are technical. As the personal element greatly predominated over the scientific element our report will be necessarily very short.

After the formal business of opening the meeting had been gone through, Mr. Crompton was called upon to reply to the discussion which has taken place on his paper on "Central Station Lighting." In the course of his remarks he reminded the members that his paper did not pretend to deal generally with the question of "Transformers *versus* Accumulators," but only with the particular phase of this question which presents itself when applied to London districts of moderate size, in which case overhead wires could not be used, and consequently the battery system would be the cheaper of the two. He had particularly in mind the lighting of residential districts, and there the load diagram would not admit of a greater sale than 2100 units per day, though in business districts the sale might reach a higher figure. He did not include the sale of motive power, as this would unfairly prejudice the alternating current system where motors could not be used; but it must be remembered that the cost of the central station would be somewhat in proportion to the peak of the load diagram, whilst the income would be proportional to the area, and since the sale of electricity for motive power increases the area without raising the peak, the use of motors would give an enormous advantage to the B.T. system. His tables of the cost of conductors were taken from actual commercial experience and were therefore correct. His bare conductor supported on insulators—not suspended from the roof of the culvert—would have an insulation resistance equally as high as the best cable, and where space could not be obtained for a culvert 18in. square, he could manage with a culvert 5in. deep by 18in. wide for an ordinary twin main or 24in. wide if a charging main were to be laid in addition. It must be remembered that there was no difficulty in getting width under the footway, but they were sometimes restricted in depth. He did not refer to the Colchester installation, because that was of a totally different character to his own. In Colchester the batteries were charged in the daytime and discharged at night, and acted as reservoirs of electricity. In his own plan the batteries and the dynamos would work together, and the efficiency of the batteries came only into question in so far as they acted as reservoirs; but since the maximum supply would be direct from the dynamo, the presence of the battery could have no appreciable effect upon the efficiency of the whole distribution. He fixed the potential at 400 or 450 volts, because he was certain that with that pressure he could do the work. It might in future be possible to raise the potential and go to a longer distance. At Vienna he had now 13,000 lights installed, the charging main being 1500 yards long. If a potential of 400 volts be considered too high, it would be quite practicable in London to work on the three-wire system with two batteries, and thus keep the potential within the limits allowed by the Board of Trade. As regards the depreciation of accumulators, the Vienna Company had received an offer to maintain them at an annual cost of 10 per cent., but they had refused this offer because they were satisfied that the depreciation will come to less. After the usual vote of thanks was recorded to the author, the adjourned discussion on the paper by Mr. Preece on Fire Risks and Fire Risk Rules was opened by Mr. Musgrave Heaphy, who gave a history of the labours of the committee at which he assisted up to the time when he left it.

Mr. Human criticised the clause of the new fire office rules referring to the insulation resistance. According to this clause the insulation resistance is not to be specified as so many megohms or ohms, but by the amount of leakage which could be allowed, the limit being $\frac{1}{3000}$th part of the working current. Mr. Human said that in most installations the working current was comparatively small, say from 15 to 20 ampères, and he did not see how so small a current as $\frac{1}{3000}$th part of 15 ampères could be measured.

The Earl of Crawford deprecated the multiplication of rules, because each rule contained some weak points, and unscrupulous contractors would choose that rule which would best suit them for doing the work cheaply. He and his friends at the Grosvenor Gallery installation have found the Phœnix rules perfectly satisfactory, and owing to the great trouble they had had with installations put up under other rules they had now come to the determination that before turning the current on to any installation they would require proof that it had been fitted up under the Phœnix rules, or that it had been inspected and passed under those rules. Referring to Mr. Crompton's statement that at the Grosvenor Gallery the consumption of coal was 18lb. per electrical h.p., he thought that Mr. Crompton must have displaced the decimal point, and must have meant 1·8lb.

Mr. Wharton considered the fire offices and the contractors the only parties who had to be consulted in the matter of fire rules, and, as far as he knew, neither party wished to have any alteration in the existing Phœnix rules, or any new set of rules imposed upon them.

Mr. Shoolbred asked the author about the relative heating effect in different sized wires, and he pointed out to the meeting that the new rules issued by the Committee of the Society were not in any way antagonistic to the existing Phœnix rules, which could still be retained as detailed rules.

Mr. Prior denied the statement that the Phœnix rules had been adopted by all the leading offices. The office with which he was connected had not adopted these rules, and did not intend to adopt any rules of this character, as it was not the business of the fire insurance company to protect the contractor or the customer from possible losses by leakage, &c. His office did not consider inspection necessary, and would not accept any rules which would necessitate the sending of inspectors to electric light installations before accepting the risk. They wanted some simple rules under which inspection would be unnecessary, and for this reason he considered the Phœnix rules totally inadmissible.

Digitized by Google

Mr. Preece, in his reply, regretted the turn which the discussion had taken, and limited himself to the scientific and technical points only. Referring to Mr. Human's question, he said that any telegraph engineer and any budding electrician in the room would be perfectly competent to measure a current of three milliampères which would be the permissible leakage with an installation using a 15 ampères working current. Regarding the question of Mr. Shoolbred, he had for some considerable time been carrying out experiments to determine the heating of wires of different sizes when traversed by currents of different intensities. In this connection he would refer to the investigation made by Professor Forbes some years ago, which, however, was based upon Macfarlane Gray's co-efficient of emissivity, which was determined in the laboratory of Sir William Thomson by means of metal spheres both polished and blackened. His own experiments showed him that the co-efficient was different for cylinders, and that the formula of Professor Forbes required correction.

CLYDE SHIPBUILDING FOR APRIL.

THE tonnage launched during April was not above, though it was up to, the average. There were in all fourteen steamers and six sailing vessels launched, and the aggregate tonnage was 15,777 tons. Included in this total is yacht tonnage amounting to 860 tons. The bulk of this comparatively large tonnage is composed of the 735 tons of the "Lady Torfrida," which Sir William Pearce has had built by his firm for his own use. The only large steamship launched was the "Spindrift," built by Messrs. Russell & Co., Greenock. One notable feature of the launching of the month is the comparatively large proportion of sailing tonnage. Four large sailing vessels, averaging nearly 2000 tons each, make up the respectable total of about 7000 tons, or nearly 50 per cent. of the whole. The new orders of the month are not significantly large, though somewhere about 4000 tons of new contracts have been booked. About ten vessels are included in this estimate, so that the average size is small. Among the orders is one for a caisson for docks in Nova Scotia, which has been entrusted to Messrs. D. J. Dunlop & Co., Port Glasgow.

Steamers: "Aid," 250 tons, patent hopper dredger, built by Messrs. Simons & Co., Renfrew, for a French firm; "Campbill," steel screw steamer, 1026 tons net register, built by Messrs. Russell & Co., Port Glasgow, for Messrs. Macbeth & Gray, Glasgow; "Cygnet," steel steam yacht, 30 tons, built by Messrs. T. B. Seath & Co., Rutherglen, to the order of Sir John Lawes; "Fusileer," paddle steamer, 250 tons, built by Messrs. J. Macarthur and Co., Paisley, for Mr. David MacBrayne; "Lady Torfrida," steel steam yacht, 735 tons, built by the Fairfield Shipbuilding Company, Limited, for Sir William Pearce, Bart.; "Luath," steel steam yacht, built by W. S. Cumming, Glasgow, for Mr. John Henry, Glasgow; "Macassa," steel twin screw, 459 tons, built by Messrs. W. Hamilton & Co., Port Glasgow, for service on Lake Ontario; "Ramleh" and "Rosette," hopper barges, each 400 tons, built by Messrs. Lobnitz & Co., for the Suez Canal Company; "Rouen," steel paddle steamer, 800 tons, built by the Fairfield Shipbuilding Company, for the London, Brighton, and South Coast Railway, for the Newhaven and Dieppe route; "Ruby," 500 tons, built by Messrs. Scott & Co., Bowling, for Mr. William Robertson, Great Clyde-street, Glasgow; "Spindrift," steel, 3000 tons, built by Messrs. Russell & Co., Greenock, for Mr. S. Y. Barwick, Sunderland; "Triette C.," steel, 250 tons, built by Messrs. W. Simons & Co., for passenger service in the Adriatic; "Volunteer," composite, 750 tons, built by Messrs. A. Macmillan & Son, for service on the Newfoundland coast.

Sailing Vessels: "Adderley," steel, 1237 tons, built by Messrs. John Reid & Co., Port Glasgow, for Messrs. C. W. Kellock & Co., Liverpool; "Harold," steel, 1360 tons, built by Messrs. Robert Duncan & Co., Port Glasgow, for Messrs. Thomas Stephens & Son, London; "Madagascar," steel, four-masted barque, 2080 tons, built by Messrs. Russell & Co., Port Glasgow, for Mr. J. W. Boyd, Helensburgh; "Marion Lightbody," steel, four-masted ship, 2155 tons, built by Messrs. D. & W. Henderson and Co., for Messrs. Rogers & Co., Glasgow and Valparaiso; "Oriel," yacht, 5 tons, built by Mr. De Fyfe, Millport, for Mr G. H. Pentland, Drogheda; "Yanara," composite racing yacht, 60 tons, built by Messrs. D. & W. Henderson & Co., Partick, for Mr. Paul Ralli, London.

Notices of Meetings.

THIS WEEK.

THE DYNAMICABLES.—Friday, 25th May, 7-30 p.m. Dinner at the Holborn Restaurant.

PHYSICAL SOCIETY.—Saturday, 26th May, 3 p.m. Papers to be read: "Note on the Governing of Electromotors," by Professors Ayrton and Perry; on "The Formulæ of Bernouilli and Haecker for the Lifting Power of Magnets," by Professor S. P. Thompson; "Experiments on Electrolysis. Part II. Irreciprocal Conduction," by Messrs. W. W. Haldane Gee and H. Holden.

NEXT WEEK.

ROYAL INSTITUTE OF BRITISH ARCHITECTS.—Monday, 28th May. Ordinary meeting. Nomination of candidates for membership. Paper and discussion.

INSTITUTION OF CIVIL ENGINEERS.—Tuesday, 29th May, 8 p.m. Annual general meeting, to consider the Report of the Council on the state of the Institution, and to elect the Council and officers for the ensuing year.

SOCIETY OF ARTS.—Tuesday, 29th May, 8 p.m. Applied Art Section. Paper to be read on "Persian Textiles," by Mr. Cecil Smith.

ROYAL INSTITUTION OF GREAT BRITAIN.—Tuesday, 29th May, 3 p.m. Lecture on "Conventions and Conventionality in Art," by Mr. S. Colvin.—Thursday, 31st May, 3 p.m. Lecture on "The Growth and Sculpture of the Alps," by Professor T. G. Bonney.—Friday, 1st June, 9 p.m. Lecture on "Earthquakes, and How to Measure Them," by Professor J. A. Ewing.

SOCIETY OF TELEGRAPH ENGINEERS AND ELECTRICIANS.—Thursday, 31st May, 8 p.m. Paper to be read on "The Influence Machine from 1788 to 1888," by Professor Silvanus P. Thompson.

GEOLOGISTS' ASSOCIATION.—Friday, 1st June, 8 p.m. Paper to be read on "The Natural History of Gypsum," by Mr. J. G. Goodchild, F.G.S.

PRICES CURRENT, 24TH MAY.

Quotations at per ton, unless otherwise specified.

AGRICULTURAL IMPLEMENTS IN SPAIN.

THE British Vice-Consul at Jerez de la Frontera states that, nothwithstanding want of capital and heavy taxation, land owners and farmers in his district have made an effort of late years to import ploughs, thrashing, reaping, binding, and sowing machines from England, Messrs. Ransome's being the principal firm from which they have been obtained. Latterly, however, agents for German and American manufacturers have established themselves at Seville, and are obtaining a large share of the trade. They keep considerable stocks not only of various classes of agricultural implements, but also of the separate parts, thus enabling the farmer to immediately replace any damaged part of his machine. This bears out the advice given some time ago by our Madrid correspondent, that English agricultural engineers would find it good policy to establish repairing shops in Spain if they desired to do business there. Those farmers who cannot afford the outlay necessary for the purchase of agricultural machinery continue to reap by hand and to thrash in a primitive fashion. In the Cordoba district, according to the local British Vice-Consul, foreign enterprise in agricultural implements meets with little encouragement; but he points out that American and German houses are doing their best to promote trade by giving long terms for payment, and adds that he thinks there is every possibility of good results.

HOME INDUSTRIES.

MANCHESTER, 24TH MAY, 1888.

THE COTTON TRADE.—This week being the popular holiday time in Lancashire, the state of the market is somewhat disorganised, and there are no special features to note. The general tone and tendency are unmistakably in favour of buyers, and this is largely helped by the extremely low price of silver, and a somewhat drooping condition of the cotton market. Silver has touched during the past week a price of 41⅛d. per oz., a quotation which we believe is without precedent. The lack of confidence which is caused by this state of the silver market immediately tells on the chief Eastern buyers, and the result is that a very slack demand exists at present prices. So far as cotton is concerned, it is now tolerably clear that the largest estimate of the extent of the American crop which was made in the early part of the season will be very materially exceeded, and the immediate result is seen in a fall in the price of all American staples. Thus there are two factors tending to produce lower prices—cheap silver and cotton—the combined effect of which is very strong. On the other hand there is no disposition on the part of spinners to yield, as they now have to face an immediate advance of wages. The replies received from the various spinning firms in the Oldham district were considered at a meeting held on the 17th inst., and were of such a nature that it became absolutely necessary to concede the advance in wages asked by the operatives. As this amounts to 5 per cent. on the wages of spinners and 10 per cent. on those of blowing room hands, there is a powerful counterpoise provided to any declining tendency in quotations. At present also there are a large number of concerns well bought in cotton and well sold in yarns, and under these circumstances a stiff opposition will be made to any attempt to lower the rates. Besides this there is a much larger home demand for all classes of yarn than ever existed before, so that, all round, the pessimists of the trade are likely to be disappointed. The cloth trade is quiet generally, more especially so in Eastern varieties. A fair quantity of contracts are running out, and there is a little pressure to replace them; but it is almost always the case when this happens that lower prices are offered and accepted. The peculiar mode in which manufacturing operations are now carried on, and the large number of small masters who now weave for the market, enable the large distributing agents and merchants to keep rates down and to make remunerative bargains. It is somewhat singular and very significant that the spinning trade tends to larger establishments and weaving to smaller ones. In the better class of cloth, such as printing varieties, there is less demand than ever, and makers are complaining a good deal. The dispute to which we have previously referred between the loomers and drawers and their employers at Blackburn appears likely to lead to a strike, which, if it occurs, will affect a body of workpeople altogether out of proportion to the number directly concerned.

STEAM IN WEAVING SHEDS.—A memorandum has been issued by the Blackburn and District Weavers' Association complaining of the emission of steam into sheds where weaving is conducted. This practice, it is claimed, is very detrimental to health, however beneficial it may be in preventing breakages. It is very likely that, if any well authenticated case was brought to the knowledge of the authorities, steps would be taken to prevent the practice, the benefits arising from which have been shown by American experience to be very slight.

THE FLANNEL TRADE.—This trade, the head centre of which in this district is Rochdale, is gradually recovering from the extreme depression of the past few years. Flannel goods have not been much worn latterly, and the revival in their employment has been accompanied by a demand for fancy and mixed goods. These flannelettes, which are a mixture of cotton and wool, are now produced in tasteful designs, and are being largely adopted. Those manufacturers who have been wise enough to keep abreast of the times, and who endeavour to make goods which take the public fancy, are fairly employed, and generally speaking there is a very decidedly better state of things existing in Rochdale than there was a short time ago. A steady business is also being done in all wool goods, and with the greater knowledge of hygienic science, these will be still further called for.

LONDON, 24TH MAY, 1888.

THE MONEY MARKET.—The money market has been comparatively easy in the absence of any strong demand for accommodation in the way of loans, and rates have consequently continued at a comparatively low figure. In the stock markets a more hopeful tone has begun to manifest itself since the "House" resumed after the holiday. Business had been absolutely dead for some days before, and as soon as work was begun again an endeavour was made to infuse a little more life into the markets. Naturally, the movement was led by home railway stocks, as the lovely weather during Whitsuntide insured a good traffic. There is still room for improvement in the markets, which are not so buoyant as might be expected. The absence of life and energy in the Stock Exchange this year is almost unprecedented, and is quite inexplicable.

COMPANIES.—The following new companies have been registered since our last report: Richard Goodair, Ld., with a capital of £100,000, to acquire the business of a merchant and cotton manufacturer carried on at Preston and Manchester; Oldham & Booth, Ld., with a capital of £20,000, to acquire the engineering business carried on at the Central Foundry, Hull; the Water Works, Gas, and General Lighting Corporation, Ld., with a capital of £1,000,000; the Monmer Lane Iron Company, Ld., with a capital of £20,000; the Marsden Chemical Company, Ld., with a capital of £25,000; the Wenham Company, Ld., with a capital of £250,000; the Pacific and Oriental Petroleum Company, Ld., with a capital of £400,000; the Schülke Gas Lamp Company, Ld., with a capital of £50,000; the Parana Water Works Company, Ld., with a capital of £100,000, to supply water to the town of Parana, Argentine Republic; the Rosario Drainage Company, Ld. (Argentine Republic), with a capital of £800,000; the San Juan and Rioja Railway Company, Ld. (Argentine Republic), with a capital of £2,000,000; the Universal Patent Fuel Machine and Manufacturing Company, Ld., with a capital of £75,000; the Great Northern, Lincoln, and East Coast Railway Company, Ld., with a capital of £75,000; the Morgan Gold Mining Company, Ld., with a capital of £210,000; the Groot Paardekraal Gold Mining Company, Ld., with a capital of £250,000; the Leadville Mines Company, Ld. (United States), with a capital of £210,000; the Rich Knob Copper Mining Company, Ld. (United States), with a capital of £200,000; the Libiola Copper Mining Company, Ld. (Italy), with a capital of £252,000; the Golden Crown Company, Ld. (Brazil), with a capital of £175,000; the Deep Navigation Collieries Company, Ld., with a capital of £215,000; Luipaards Vlei Estate and Gold Mining Company, Ld., with a capital of £250,000; and the Kadur-Mysore Gold Mines Company, Ld., with a capital of £100,000.

RAILWAYS.—The gross receipts of the twenty-three principal railways in the United Kingdom for the week ending 13th May, amounted to £1,219,233 on 15,852 miles, as compared with £1,188,010 in the corresponding period of 1887, when the mileage was 15,728½ miles. An increase is thus shown in the mileage of 123½ miles or 0·7 per cent., and in the receipts of £31,223 or 2·6 per cent. A Blue Book has been issued containing a return of the accidents on the railways in the United Kingdom during last year. Under the heading of accidents to trains, rolling stock, and permanent way, it appears that twenty-five passengers were killed and 538 injured, as compared with eight killed and 615 injured in 1886; eight servants of companies were killed and 109 injured, as compared with four killed and eighty-one injured in the previous year. The number of deaths of passengers from collisions was thirty-three, and the number of injured 647, as compared with twelve and 696 respectively in the previous year. By accidents from other causes ninety-six passengers were killed and 759 injured, as against eighty-seven and 727 respectively in 1886. The total number of personal accidents reported to the Board of Trade during last year amounted to 977 persons killed and 7747 injured.

PARIS EXHIBITION, 1889.—The Executive Council of the British Section announce that they are prepared to receive applications from intending exhibitors up to the 9th of next month, at which date it will be absolutely necessary to commence the allotment of space. It appears that very little, if any, more space can be given to this country, which already has a large proportion of the amount allotted to foreigners, the demands made by native exhibitors having been unexpectedly large.

SANITARY INSTITUTE OF GREAT BRITAIN.—At the annual general meeting, held at the Parkes Museum last week, Professor W. H. Corfield, M.A., M.D. (chairman of Council), in the chair, a report was presented by the Council on the work of the Institute during the last year, and on the Congress at Bolton in the autumn of 1887. The chairman gave an address, and the officers for the ensuing year were elected: President, the Duke of Northumberland, K.G., and trustees, Sir John Lubbock, Dr. B. W. Richardson, and Mr. Thomas Salt, M.P.

GLASGOW, 24TH MAY, 1888.

GENERAL BUSINESS.—There is a considerable want of life in general business; prices both in the metal markets and in stocks are not exhibiting any signs of expansion. There is a slight increase in shipments of pig iron, but no corresponding increase in price. Shipbuilding and engineering orders are neither numerous nor important. The retail trade of the shops, which ought at this season to be brisk, has been affected both favourably and prejudicially by the Exhibition. The influx of strangers has brought brisk trade to some classes of shopkeepers, but others complain that their customers are entertaining themselves otherwise than by purchasing, and that except in dress goods, printing, and a few trades specially affected by demands for the Exhibition, there is little being done.

GLASGOW EXHIBITION.—In point of attendance, the Exhibition is a phenomenal success. The numbers are much greater even than the Indian and Colonial Exhibition in 1886. The average daily attendance during the first twelve days reached the large total of 35,994. The corresponding figures for the Indian and Colonial Exhibition were 21,833, for Manchester 21,720, for Edinburgh 19,122. The building, large as it is, is inconveniently crowded when upwards of 30,000 are within its gates at one time. It is found that the Grand Hall, which is seated for about two thousand, is altogether too small. The Whitsuntide holidays have brought into town a large number of English visitors. There can be no doubt that the financial success of the Exhibition is already assured. A singular economic result from a banking point of view is the direction into the hands of a single bank—the Clydesdale—which has an office in the building, and which finances for the Executive, of the relatively large sum of from £500 to £1,000 in small silver coins per day. A careful watch has to be kept at the turnstiles for foreign and counterfeit coins, of which already a considerable quantity has been passed, the pressure at every entrance in the evening rendering detection difficult.

PIG IRON.—A hematite furnace has been put in blast at Gartsherrie, bringing the number of furnaces now in operation in the district up to eighty-eight. This is an increase of seven furnaces over the same week last year. A fairly large quantity in warrants has changed hands, but the price has not yet made any upward movement.

(From our own Correspondents.)

LIVERPOOL, 23RD MAY, 1888.

THE PACIFIC STEAM NAVIGATION COMPANY.—On account of the prevalence of cholera during the last year in Chili and Peru, many of the ports had to be closed, and for the same reason vessels ceased calling at Monte Video and the Brazilian ports. Although these ports were not actually closed against vessels sailing from Chili, the rigorous and expensive quarantine enforced practically made them so. This has reduced the coasting traffic of the company to an unprofitable limit, and several of the steamers had to be temporarily withdrawn. Excessive competition on the West Coast, Straits, and the Australian line, has compelled the adoption of reduced fares in order to compete with the inducements offered by foreign companies. From the report of the directors it appears that the profits on the working account last year was £171,684. The profit and loss account, after the usual debits were made, including £159,648 for depreciation, &c., shows a credit balance of £5,940 for the year 1887. An interim dividend of eight shillings per share was paid in November last from the balance of £28,935 brought forward from 1886. The final credit balance for last year being only £11,658, the directors have decided to carry it forward to the 1888 account.

PASSENGER TRAFFIC TO THE VARIOUS WATERING PLACES.—The summer excursion season has now fairly commenced, all the boats to the Isle of Man, Llandudno, and other places being well patronised; what with last Monday being a Bank Holiday, and the exceptionally fine weather, the traffic to the Isle of Man was enormous and quite unprecedented; all the steamers of the two companies were brought into requisition, and no less than eight left the stage during the day with about six thousand persons on board. Forced draught has been applied to the "Mona's Isle" and others of the Old Manx Line with satisfactory results, and some interesting races have since taken place between the boats of the competing companies; the "Queen Victoria" of the new company is, however, still able to give her opponents fully half an hour's start.

SHEFFIELD, 23RD MAY, 1888.

THE HEAVY INDUSTRIES.—During the early part of the week there was a general holiday, but a vast amount of work was done in forwarding and completing orders in order to prepare for the holiday, and all the houses making heavy material have still a good number of orders on their books. Bars, hoops, angles, indeed all kinds of iron, can now be bought so cheaply, and the quotations for Bessemer steel are so easy, that manufacturers are not making a great profit even on urgent contracts; still the low prices are tempting buyers, and not only makers but merchants have turned over a vast amount of material during the past month. The fall in the price of coal has also tended in some quarters to a better demand, especially with houses that find it absolutely necessary to cheapen production. It is encouraging to find in the midst of complaints about the unremunerative condition of the iron trade that the Parkgate Iron Company, near Sheffield, has made a profit of nearly £7,000 on the year. Work is plentiful there, and its blast furnaces, plate and sheet mills, and puddling fires are kept going steadily. When the new plant for steel manufacture by the Siemens-Martin process is put down, the firm hopes to develop a very extensive steel trade. There is all round a tendency to extend steel manufacture, and additions both to crucible and Bessemer steel making plant are being put up by local firms. The talk about national defences has revived hope in Sheffield, but that is all it has led to at present. The special machinery built in the new shops of some of the great Sheffield firms on the expectation of Government orders is for the most part lying idle, and an enormous amount of capital has been, so far, practically wasted. Railway material continues in good request. Tyres, axles, and springs are on extensive order, both for the home and colonial markets. One or two good orders for rails have been placed during the week. At the rolling mills there has been considerable activity up to Whitsuntide, and in the engineering shops employment has been by no means scarce. A great deal of heavy machinery is on order, and in the boiler shops work is not so difficult to obtain. The crisis in the shipbuilding trade of the North will benefit one or two local firms, but it is to be regretted that the difficulty has arisen. The trade in edge tools is brisk. Makers contrive to keep opening new markets, and all kinds of articles, handy, useful, and cheap, are being

Digitized by Google

shipped to the Colonies, and to more remote markets. The intention of the Government to keep open the passage of the Zambesi has given much satisfaction here. Sheffield already does an extensive African trade, chiefly in kind. Before long another advantage may be derived, on account of the cost of the transit of ivory being much decreased. Colliery plant, such as machinery, hauling wire, and pit rails, is in fairly good demand.

NORTH STAFFORDSHIRE, 23rd May, 1888.

The Iron Trade.—This week the works are all closed for the Whitsuntide holidays, and the market is quiet. The outlook is unfavourable both with regard to prices and demand. Manufacturers are interesting themselves in the question of railway and canal carriage, as owing to its landlocked position the maintenance of trade in this district much depends upon the prospect of reduced charges for transit to the coast.

The Coal Trade.—Now that summer weather is really upon us, there is a great falling off in the coal trade for domestic consumption, and in consequence of the keen competition prices are being reduced. The demand for manufacturing fuel for the pottery industry is fairly good. Messrs. Johnson Brothers are building a new manufactory at Hanley, and hope to have it completed before the autumn.

Engineering.—Founders still complain of low prices and poor demand, and there is little margin for profit in the rates at which orders have to be booked. Foundry coke is in but poor request, and most of that used locally comes from the Durham ovens.

BIRMINGHAM, 23rd May, 1888.

The Iron and Hardware Trades.—The markets in the iron trade are dull, but pig iron remains fairly steady. Buyers, as usual at this season, are unwilling to purchase, and probably little activity will be manifested until the holidays are over. Staffordshire all mine hot blast pig is firm at 52s. 6d. to 57s. 6d. per ton, and marked bar iron brings £7, although with some difficulty. Black sheets are selling freely, the reduction in the price of galvanised iron having stimulated this branch of business. Several offers for thick sheets have been refused by makers at £6. 5s. for 24-gauge. Steel is in good request, and sheets up to 20-gauge are worth £7. 5s. In the hardware trade production is almost at a standstill, and many firms have closed until Thursday. The continued high price of copper continues to harass the copper and brass trades. Standard brass wire is quoted at 8½d. per lb., but brass tubes find only a limited demand. In the jewellery trade matters are a little better; the demand for silver goods has somewhat subsided, and gold articles, ornamented with jewels, have taken their place. Travellers report that fashion appears to be again returning towards the wearing of jewellery, and the fine weather is opportune to the revival. Electro-platers and manufacturers of white metal goods report great quietness in trade; the orders for home requirements are very meagre, and the only activity appears to lie in the direction of Colonial markets. Makers of common white metal spoons, coffee house appliances, bar fittings, cork drawers, and general pewter ware are busy. Iron wire drawers continue to feel the German competition very keenly, particularly in foreign markets; in the home markets English manufacturers are steadily regaining their predominance. The action of the Government in deciding to remove to Enfield the plant of the local ammunition and small arms concern, which they recently bought, is giving much dissatisfaction; it is considered in this district that not only will their action result in injury to the local gun trade, but will tend to weaken the national defences in case of a crisis.

LEICESTER, 23rd May, 1888.

Wool Spinning and Yarn Trades.—The condition of the wool market remains almost unaltered so far as prices are concerned, whilst the turnover has been very restricted. Staplers who are not heavily stocked stand out for the late prices, and as a rule sales are not pressed. Users content themselves with buying as small quantities as possible. An uncertain element in the market at present is the new clip, and until this has been seen and judged for quantity and quality, prices cannot be fixed. As a rule the heavier sorts are best in demand, and fine wools are very slow. Spinners have not been any better employed, and the present state of the industry is very discouraging. The incidence of the holidays this week has enabled them to let the machinery stand for the week, and it is likely that much of it will be run short time on the commencement of work next week. Sales are only effected at most unremunerative prices, and it is deemed better to let the machinery stand than take orders at rates offered. Yarn merchants are doing anything but a satisfactory business, the unstable state of the market making itself much felt in their department. The demand is best for cashmeres. Cotton yarns are in very quiet demand.

Hosiery Trade.—Somewhat better business is now being done in this industry, and some of the houses are very busy. Those manufacturers who produce specialties are busy and on full time. Medium goods are most in demand, the chief inquiries in the plain department being for cashmere hose and underwear. Fancy hosiers, too, are much better employed, and the trade generally is quite up to its usual average.

Boot and Shoe Trade.—Last week was a busy one, and a heavy turnover was made, mainly in goods ordered for the holiday trade. Orders are more plentiful, and on the resumption of business after the holidays, the workpeople will be more fully employed. The leather trade remains rather quiet, consumers only ordering for immediate wants. The rates rule very low, and the market generally is depressed; and though it is so much in favour of purchasers, yet very little trade is done of a speculative character.

BARROW-IN-FURNESS, 23rd May, 1888.

Iron and Steel.—There is a quiet tone in the hematite pig iron trade, and makers are not in receipt of many new contracts. They are certainly not pressing for orders, and users of iron are not in want of early deliveries of large parcels of metal. There is a large delivery of Bessemer pig iron to steel makers, and as the latter are sure to be busy throughout the year, the mainstay of the hematite pig iron trade is assured; but there is not much hope of any improvement in the prices of pig iron so long as stocks remain as large as at present. As those stocks are for the most part held by second hand dealers, it is easy to see that in times of depression or inactive demand their sale will be frequently effected. Last week's rates are still quoted—Nos. 1, 2, and 3 Bessemer at 42s. 6d. per ton net f.o.b., and No. 3 forge at 41s. 6d. per ton. Hematite warrants have changed hands at fully 1s. and 1s. 6d. per ton below these figures. In the steel trade there is much activity, and the works are very fully employed, and makers are well sold forward. Rails are in good demand; but makers find it impossible to raise the prices, which remain at £3. 17s. per ton net at works or f.o.b. for heavy sections. The mills are very busily employed. Every effort is being made to increase the output of Siemens-Martin steel in the district. In fact, the plant is being doubled, and it is probable that before two or three months the output of plates, angles, and other classes of light goods in mild steel will be fully 1000 tons per week in Barrow alone. Ship plates are in good demand at £6. 15s. per ton net f.o.b., and angles at £6. 2s. per ton. Makers have plenty of orders on their books, and others of some importance are offering. In billets, tin bars, hoops, wire, &c., there is a good trade being done, and all round there are signs of a long continuance of activity in this trade. In shipbuilding a much brisker trade is talked of after Whitsuntide, and there is reason to believe this anticipation will be realised, as also in the engineering, boiler making, and forge trades. The output of iron ore is steadily maintained, but the trade is quiet; prices show no improvement from old rates, which are 8s. 6d. to 11s. 6d. per ton net at mines.

The Import Timber Trade.—There is every prospect of a large import timber trade at Barrow this season, for not only have the Naval Construction and Armaments Company arranged for heavy deliveries of teak wood, pitch pine, and other classes of wood used in shipbuilding, but timber merchants and others have had consigned to them many heavy cargoes of all classes of timber.

Barrow and the Petroleum Trade.—Mr. David Caird has already commenced his contract for the erection of a large storage for petroleum on the docks at Barrow. It is expected that this new trade with Barrow will be opened in a month or two.

MIDDLESBROUGH, 23rd May, 1888.

Pig Iron.—The holidays have prevented any business being transacted during this week. At the weekly meeting held on 'Change yesterday, there were not a couple of dozen persons present. There is no change in price, which is merely nominal at 31s. 3d. for No. 3 G.M.B. for early delivery, and 31s. 6d. for delivery over the third quarter Warrants are 31s. per ton cash for Connal's No. 3 G.M.B., and 42s. 6d. for hematite Nos. 1, 2, and 3.

Shipments of Pig Iron.—Contrary to expectation, the shipments of pig iron continue unabated. No doubt the low price has had its due effect, so that Continental stocks are being more than replenished in all probability. Germany and Holland still lead the way, almost equalling Scotland between them in their demands.

Shipbuilding.—The wage difficulty is again threatening to disturb the trade. The masters have decided to resist. It is considered very unwise on the part of the men to raise the question at all at this time.

Salt.—This industry is growing apace, and very little stock is allowed to accumulate, the demand is so constant and steady. It chiefly goes for chemical and agricultural purposes, but there will also shortly be a demand for fish curing as well.

NEWCASTLE, 23rd May, 1888.

Rope Works.—The demands of shipbuilders for wire rigging and other descriptions of rope required on shipboard are now becoming very pressing, and rope making firms which make that class of work a specialty, are exceedingly busy. The proprietors of several Northumberland collieries have lately placed important orders for wire rope in the district, and considerable quantities have also been ordered for exportation. On the whole, the rope trade may be said to be in a very healthy condition, and so long as business is maintained at its present level manufacturers will have little cause to complain.

Glass Works.—Flint glass manufacturers at Gateshead, Teams, South Shields, and Lemington are able, through the pressure of orders now existing, to keep their establishments actively going, and this somewhat unusual briskness is likely to last for some weeks to come. The lamp chimney trade is becoming busier, and in the bottle making trade a very decided improvement has taken place since the beginning of the year. Very remarkable success has attended the efforts of the Gateshead Stained Glass Company in developing their business, a circumstance which is fully attested by the fact that orders are now coming in from all parts of the country.

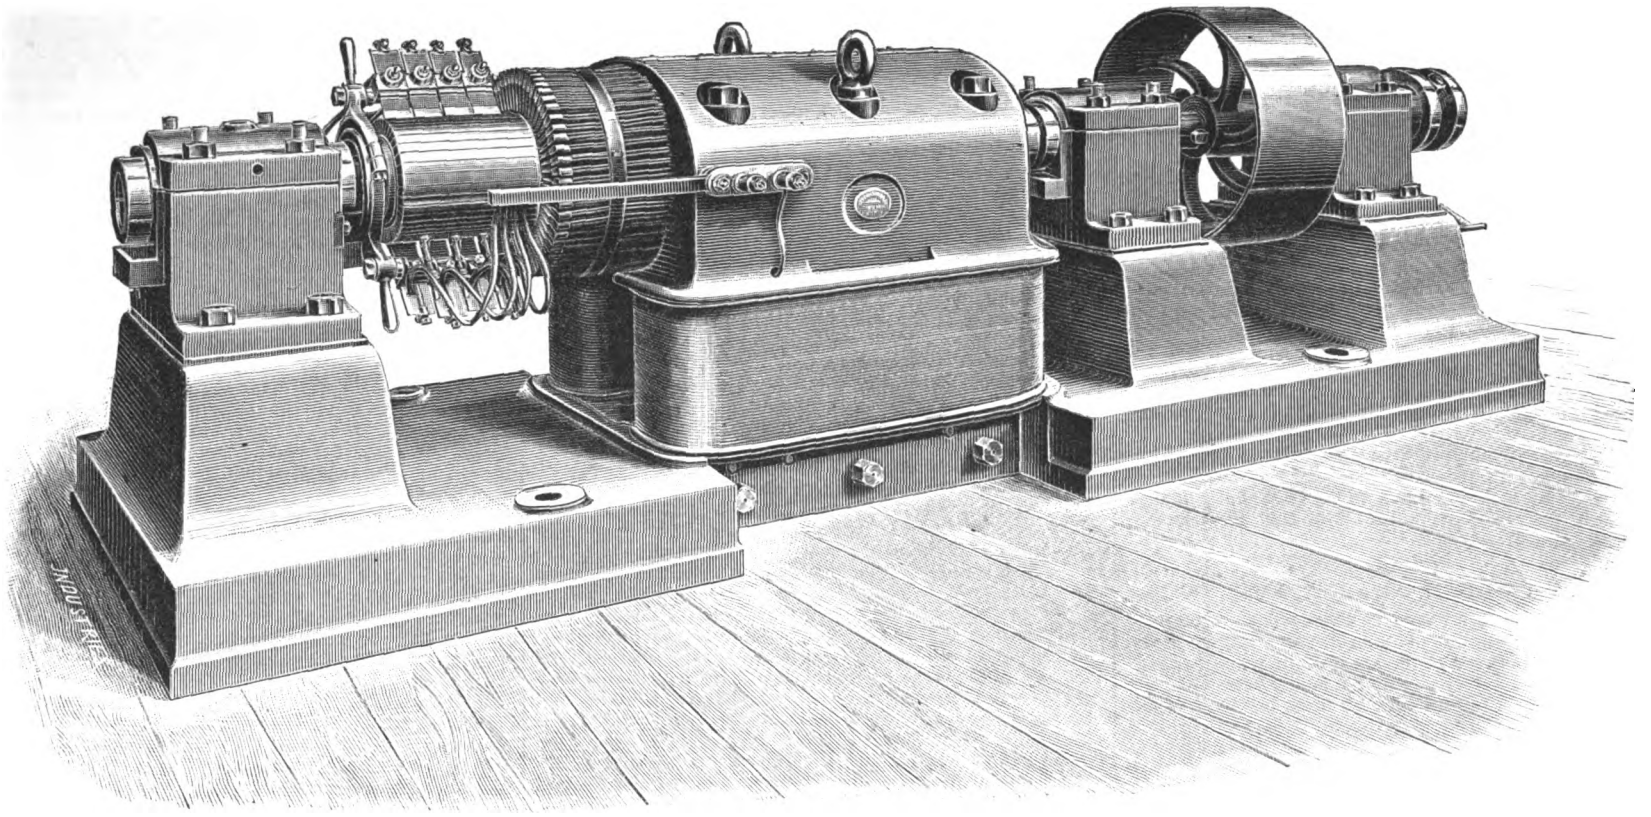
Potteries.—Manufacturers of the various descriptions of white ware are generally well supplied with orders, and at most of the local establishments a satisfactory output is maintained. In the matter of values, however, no perceptible improvement is to be noted.

Fire Brick Works.—The demand for fire bricks and sanitary pipes has greatly strengthened within the past few weeks, and the output from the works has greatly increased. Large quantities of these classes of goods are being shipped to foreign destinations.

The Timber Trade.—The number of arrivals of timber laden vessels at Tyne Dock is increasing each week, and in a short time the season of activity in this trade will be at its height. There is much more work for the saw mills than at this time last year, the main cause of the improvement being the increased requirements in connection with ship construction.

The Coal Trade.—The demand for gas and household coals has slackened very much since the beginning of the month, and many of the pits which produce these qualities are now on short time. In the steam coal trade, however, business is daily becoming more animated. The united exports of coal and coke from Tyne Dock during the week ending May 19th, amounted to 91,391 tons. This is a decrease of 3961 tons as compared with the corresponding week of last year.

The Tyne Shipbuilding Trade.—A very serious obstruction to business has just occurred in the Tyne shipbuilding trade. The platers' helpers at Messrs. C. M. Palmer & Co.'s Jarrow yard having been refused an advance of wages, struck work early in the month, thereby practically putting a stop to the operations of the establishment. The Jarrow helpers showing no disposition to return to work without the advance, which, in present circumstances, the employers found it impossible to concede, retaliatory steps by the latter became necessary, and as soon as such measures were decided on, they were very quickly carried out. Towards the close of last week a number of new hands were obtained to supply the places of those on strike at Jarrow, and it was decided at a meeting of the shipbuilders that the helpers employed in the other yards should be discharged. This was done on Saturday last, excepting in two or three establishments whose proprietors do not belong to the Shipbuilders' Association. It was expected that this action of the employers would cause the Jarrow helpers to withdraw their demand for an advance, but as yet they have not done so.



The Sunderland Gas Engine.—Messrs. Ridealgh and Fairman's Sunderland gas engine is now a recognised success, and the demand for it is extending at a rate almost beyond the capabilities of the manufacturers to cope with. They will shortly receive in their shops, however, some new and extensive machinery, and the productive capacity will consequently be largely increased. The firm have now about a score of engines in progress, besides one which is finished, and will at the end of this week be forwarded to the London firm by whom it was ordered. A Newcastle firm of printers, who were among the first to adopt this engine as the motive power in their works, have just received from Messrs. Ridealgh & Fairman a second engine, and have now entirely dispensed with steam as an actuating power for their machinery.

DUNDEE, 23rd May, 1888.

Flax and Jute Trades.—The staple industries of the town and district are moderately active. In the linen branch sellers are more anxious than buyers, and prices are barely maintained; in the jute branch, however, the tendency is in favour of sellers. Flax is coming forward in sufficient quantity to keep spinners fully employed, and there is consequently only a limited spot business, and prices tend rather in favour of buyers. There is more doing for shipment, both in Riga and Petersburg flaxes. Flax and tow yarns command a moderate sale, but prices show no actual improvement. Foreign wet spun yarns are offering at cheap rates. Orders for linens are coming in freely, and manufacturers, more especially in Fife, are well foresold, and holding for rather higher rates. In the heavier classes of goods, such as sail cloth, only a moderate business is passing at late quotations. There has been more inquiry for jute on the spot at about late prices, and there is more disposition to operate on the new crop. For jute yarns the demand continues to be active, and a considerable business has been transacted at firm prices. Spinners are fully engaged, but fresh orders are not abundant at the full advance asked. In jute fabrics Hessians are in good request, and prices are rather higher. The prospects are in the seller's favour, and the tendency is towards increased firmness rather than towards any concession. A moderate business has been done in sacking, and bagging and tarpaulin are very saleable, with an upward tendency in prices.

THE GOOLDEN-RAVENSHAW DYNAMO.

General View.

FIFTY KILO.-WATT GOOLDEN-RAVENSHAW DYNAMO.

The present tendency in dynamo building is in the direction of increased size. Some five or six years ago, when the manufacture of dynamos was with most firms but an infant industry, machines capable of running 100 or 200 glow lamps were considered fairly large, and constituted productions of which the manufacturer was justly proud. Compared with the original Gramme machines, a 200-lighter was undoubtedly a great achievement; but at the present time such a machine is considered almost a toy as compared with the powerful dynamos which are now made as regular articles of commerce. The three machines required for the Bradford installation, for instance, will each have an output of 85 kilo.-watts, and we recently saw in a Continental works two machines in course of construction, each for an output of 120 kilo.-watts; and 100 kilo.-watt Edison machines for central station lighting are by no means unusual at the present time, to say nothing of alternating current machines, the power of which is expressed by thousands of glow lamps. In most cases large dynamos are direct driven by special engines; but occasionally belt driving is resorted to, and we illustrate above a belt driven machine made by Messrs. Goolden & Co., of Halifax, to the design of Mr. W. H. Ravenshaw. This machine is interesting, not only on account of its size, but also because it contains several contrivances which the increase of size rendered necessary.

As will be seen from the illustration, the machine is of the "over" type, with the yoke in the bed plate and the armature above. It has an output of 500 ampères at 102 volts pressure when driven at 375 revolutions per minute. The armature is of the drum pattern, with internal ventilation, and the conductor consists of six 192 mil. wires in parallel, there being 120 conductors counted all round the armature. Its resistance is ·0066 ohms, and the resistance of the field magnets, which are plain shunt wound, is 6·3 ohms. The total useful induction through the armature core is about 2300 English lines. The armature core consists of the usual iron discs, which, however, do not fill the whole interior, but are of the same dimensions as used by Messrs. Goolden & Co. for Gramme armatures, and are mounted upon the spindle in the same manner. There is thus gained an internal space for ventilation, and a sleeve is fixed over the shaft on the pulley side, leaving an annular space for the admission of air, which is drawn through the armature by means of a fan placed between the commutator and the armature core. By an ingenious method of winding, the ends of the armature are left flat, and not bulging out as in the Hefner Altenek winding, thus economising in length of wire. The magnet cores are of wrought iron, bolted to the bed plate, and the pole pieces are of cast iron, fastened to the magnets by strong bolts, as shown in our illustration. The exciting coils are made with their long sides slightly bulged, so as to cause the wire to lie tightly, and at the same time provide ventilation between the surfaces of the magnets and the internal surfaces of the exciting coils, a suitable slot being left in the flange of the pole piece, as shown.

In this machine a special device has been introduced for giving to the armature a definite to and fro motion lengthwise, in order to keep the bearing surfaces and the surface of the commutator in good condition. It will be remembered that in some of the early Edison machines a similar rocking motion was introduced by means of a spring pressing against the end of the shaft, and several dynamo makers have adopted the rule to allow the shaft a little play endways between the bearings, relying on the side motion of the belt to keep the armature rocking to and fro. This plan, although it works fairly well in certain cases, is not always satisfactory. The armature is often found to rock too violently, and thus produces knocking between the collars on the shaft and the ends of the bearings. To overcome this difficulty and yet obtain the advantage of a variable position of contact between the brushes and the commutator, Mr. D. Halpin has devised a special brush holder and gear by which the brushes are slowly shifted backwards and forwards in a direction parallel to the spindle; but a more simple plan is to make the clearance between the collars and bearings larger than the distance through which the armature rocks. The field magnets exert an attraction upon the armature in the direction of the spindle if the centre of the core of the armature does not exactly coincide with the centre of the pole pieces. If the armature be shifted out of this position of symmetry, the field magnets will pull it back, and the force thus exerted is quite sufficient to limit the oscillation to either side of this normal position. This plan answers well in small and medium sized machines, but for very large machines it is obviously better to prescribe the path through which the armature shall rock, and this is done in the present design in the following way: To the end of the shaft outside the bearing is fixed a cast iron disc, and between this and the bearing there is loose on the shaft a second cast iron disc, with an inclined face. On a spindle at right angles to the shaft and secured to the fast disc is a loose roller touching the opposed surfaces of the two discs. The external diameter of these discs is slightly different, and against their periphery is pressed, by means of a spring, a paper roller running loose on a stud. The centre of the armature core is set slightly back as compared to the centre of the field magnets, so that the magnetic attraction tends to pull the whole armature forward towards the commutator bearing, thus keeping a certain pressure between the two discs and the roller. It will now readily be seen that, as the armature revolves, motion is imparted to the paper roller by the fixed disc, and the paper roller in turn causes the loose disc to revolve at a speed which is slightly different from that of the shaft and fixed disc. The diameters of the two discs are so chosen that the relative movement of the loose disc against the fixed disc is two complete revolutions per minute, and the whole armature receives therefore two complete out and in motions per minute, by which means the position of the brushes on the commutator is continually varied lengthwise, and scoring is entirely prevented. The longitudinal motion has also the advantage of preserving the bearing surfaces in perfect condition. The total weight of the machine is 6 tons.

H.M.S. "MAGICIENNE."

It will be remembered that the Government have now in course of construction five fast cruisers. These vessels are to be of a new type, their leading feature being a combination of high speed, quick-firing guns, protective deck, and moderately heavy armour. Three of the vessels of this new class are being built in royal dockyards at Chatham and Portsmouth, and two of them are being built by the Fairfield Shipbuilding Company, Glasgow. The first of the fleet to be launched was the "Magicienne," which left the ways at Fairfield on Saturday, the 12th inst. The vessels are of a displacement of 3000 tons, and their engines are of 9000 h.p. The speed expected to be obtained is 20 knots. The engines are being made by Messrs. Hawthorne, Leslie, & Co., Newcastle-on-Tyne. The hull is 265ft. long, 42ft. broad, and the moulded depth is 23ft. It is divided into seventy-five water tight compartments, the engine and boiler space consisting of four of these. The steel protective deck is 1in. thick in the centre, and is 2in. thick in the angles. There are two complete decks running fore and aft. The vital parts are all below the water line. The stem consists of a casting of phosphor bronze, the stern post being made of the same material. The armament will consist of nine 6-pounder Hotchkiss guns, a number of Nordenfelt guns, and six 6-inch 5-ton Armstrong guns. The engines will consist of a pair of horizontal surface condensing engines, the dimensions of the cylinders being respectively 34½in., 51in., and 76½in. diam.; stroke 36in. There are four double ended cylindrical boilers to work at a pressure of 155lb., with a grate surface of 456 sq. ft. There are twenty-four corrugated furnaces. The second vessel of the new class is the "Marathon," which will soon be ready for launching.

Advertisements intended for insertion in the current week's issue must reach the Manchester Offices not later than first mail delivery on Thursday morning. Scale of charges for displayed advertisements on cover and inside pages will be forwarded on application. Orders for single advertisements must be accompanied by payment in order to insure insertion, the charge for which is 2s. 6d. for the first four lines or under, and 8d. for each additional line; one inch and over at 7s. per inch; the line averages eight words. While all practical regularity in the insertion of serial advertisements will be observed, it can only be absolutely guaranteed in the case of those ordered to appear weekly.

All accounts are payable to the Publisher, JAMES F. BUTTERWORTH, *70, Market-Street, Manchester. Cheques should be crossed Manchester and Liverpool District Bank, King-street Branch, Manchester. Post Office Orders to be made payable at Manchester.*

Offices for Publication:
22, Wellington-street, Strand, London, W.C.

FRIDAY, 25TH MAY, 1888.

THE NATIONAL DEFENCES.

THE members of Her Majesty's Government must for some time past have had a difficult task in attempting to please those who were urging upon them the necessity for greater economy in the expenditure of the national finances, and at the same time those who were pointing out the inadequacy of our national defences. On this latter subject there can be no doubt but that we have been passing through one of those periodical scares which are largely got up by one-sided politicians, or by interested parties. While, of course, we strongly advocate the necessity for keeping ourselves well prepared for any probable emergency, we strongly deprecate the hysterical style which is indulged in by many journals, and we think the Lord Mayor was quite right in his remarks when he refused the use of the Mansion House for a public meeting for the discussion of the subject, as he was of opinion that it was highly unpatriotic to raise and keep up panics which were quite unjustifiable. It is not the sign of strength, but, on the contrary, of weakness, to get into a state of nervous excitement over a clever article which has been written by a man who may be suffering from indigestion or disappointment, or over a speech by an able general who has failed to obtain all he asked for from the Government of the day. The now celebrated speech which Lord Wolseley delivered on the occasion of the banquet to Sir John Pender, seems to have been an escape of passion engendered by the failure of urgent professional representations to bring about needed reforms, although he seems to have used much stronger language at the banquet than ever he did in his official correspondence. He strongly disclaimed, however, all intention of making an attack on the Government, and said he was convinced that no unprejudiced person, no matter who he might be, whose mind was not warped by the habitual contemplation of party politics, could calmly have read what he said, and have construed his remarks into an attack on Her Majesty's Government. His chief object was to show that the subject of the national defences has suffered from being made the convenient instrument of party intrigues, instead of being elevated into a plane above all such considerations. If in the speech referred to, Lord Wolseley had maintained the dignity he displayed in the House of Lords, when referring to the personal remarks of the Marquis of Salisbury, he would have had more sympathy from all classes of men who love their country more than their party. On that occasion he repeated part of the evidence he gave before the Royal Commission eighteen months ago, and some of his statements are certainly grave enough. He complained that we never take the English people into our confidence, we never tell them what are our shortcomings, and consequently they have no means of ascertaining the military views of the highest military officers they employ. He was still of opinion that the position of England at the present moment, as regards its army, is very unsatisfactory, and that if a hostile force of say 100,000 men were to land upon our shores, there is no reason why that force, if properly led, should not take possession of London. We have in a previous article considered the defence of London, and in view of the importance of the subject, and of the gravity of the opinion expressed by Lord Wolseley, we may soon return to the subject again; but in the meantime we may say that if such a force were to effect a landing, our defenders will be culpable in the highest degree. We venture to predict, however, notwithstanding our shortcomings, that should such a force land, few would ever return except as prisoners of war.

At the same time we agree with Lord Wolseley when he says that people are too prone to care little for the organisation of the army, and take it as a matter of course. Everyone tells us at public dinners, and in speeches delivered from both sides in either House of Parliament, that the army and navy have always done their duty and will do it in the future, and as a rule we take these views as correct, carry them home with us, and think we can sleep quietly in our beds because the army and navy are strong enough. We forget, however, that circumstances have changed much since we last took part in a great war, that our possessions and consequent responsibilities have much increased, and that the armaments of our probable antagonists have been growing at an immense rate. While giving the present Government every credit for having keenly and ardently at heart the efficiency of both the army and navy, and for having introduced many and beneficent changes into their organisation, during the time they have been in power, still, in view of our increasing responsibilities, he held it was absurd to say that these had been kept up in proportion to these responsibilities. Taking the army for instance, it has been found necessary by the Administration of India to increase their military force by ten thousand men. We have had within the past few years to maintain a force in Egypt, where we have accepted greatly increased responsibility, which may entail at any moment the necessity of sending out large reinforcements. We have also very recently become aware, thanks to a commission which sat and reported on the subject, of the condition of things abroad in our fortresses and coaling stations throughout the world, and also to our home defences. We are obliged to send considerable reinforcements to our foreign stations, so that when it is said that since 1884 there has been an increase of nearly twenty thousand men to the army, the information is altogether misleading. Moreover, as a matter of fact, the army is at present 23,000 less than it was in 1860, 16,000 less than it was in 1862, 8000 less than it was in 1863, and 7000 less than it was in 1864. Lord Wolseley concluded his speech in the House of Lords with what he called an exposition of his faith on the subject. He said: As long as the navy is as weak as it is at this moment, Her Majesty's army, dispersed as it is, cannot hold its own all over the world. Our defences at home and abroad at the present moment are in an unsatisfactory condition, and our military forces are not organised or equipped as they should be to guarantee even the safety of the capital in which they were at the present moment. He said he quite felt the responsibility incurred in making this statement; but, at the same time, there was no need whatever for panic. He appealed to reason to show that there is no imminent danger pending over the country, and that therefore there is plenty of time to do all that is necessary to place at least the army in a state of efficiency before its services are required. Panic is the offspring of

Digitized by Google

ignorance. For the people to realise their danger, and the power of meeting it, is the first step towards doing all that is required.

The Prime Minister, in the course of his reply, referred to Lord Wolseley's confession of faith, but said that he could not remember having heard it before. It surely cannot therefore have been often repeated in Ministerial ears. He admitted that it was a very grave statement, and that it would receive the most serious consideration. Alluding, however, to Lord Wolseley's remarks on the present weakness of the navy, he said that weakness and strength are relative terms, and lest a wrong impression should be created regarding the exertions this country has made, now for several years, to place its navy in a condition fit for the great duties it is called upon to perform, he wished to state what had been done since the year 1880, the beginning of the last Administration. In 1881-2 the total was £2,100,000; in 1882-3, £2,447,000; in 1883-4, £2,592,000; in 1884-5, £2,927,000; in 1885-6, £4,895,000; in 1886-7, £5,095,000; in 1887-8, £5,358,000; and in 1888-9, £5,467,000. The annual expenditure on the construction of new ships and armaments has risen since 1880 from £2,100,000 to £5,467,000. He further pointed out that in considering strength or weakness we must always take into account our probable allies, and he protested with vigour against the statement made by Lord Wolseley that public men, for the sake of making a good Budget and winning a party advantage, would consciously risk the interests of the Empire. Lord Granville, with his usual quiet banter, reminded the House of Lords of the old story of Dean Swift, who, in his "Instructions to Servants," advised the servant in a particular department to ascertain the gross amount of his master's income, and to endeavour to apply the whole of that income to his own particular department. No doubt the difficulty is largely a financial one, and the problem before the Government is to make the most of its resources, by apportioning them according to the just demands of its various interests; and in view of the great importance of the subject and its bearing on the industries of the country, we intend to keep our readers informed regarding some of its most important bearings.

TECHNICAL EDUCATION IN NEW SOUTH WALES.

Some time ago we gave a short account of the progress which was being made in technical education in New South Wales (see *Industries*, Vol. II., page 564), and we did so, not only because of the interest which the work was likely to excite on its own account, but also because we felt that the action of our Colonies in this matter was likely to have a most important bearing on the future of the trade and industry of this country. Further, we hoped to impress on our readers the fact that if new countries found it necessary to attend to the organisation of their scientific and technical education, in order that they might be able to develop their resources, it is still more necessary in a country like our own, where in many cases the materials of construction or manufacture are beginning to be somewhat scarce. Moreover, with us manufactures are absolutely necessary for our existence, whereas in the Colonies land is still abundant and sufficient for the population.

The Colonies do not by any means rush into any ill considered scheme of education which is placed before them; but before taking any decided steps, they make inquiries in all quarters in which they are likely to receive useful information, and these inquiries are generally conducted by special commissioners. Although New South Wales has made a good start in organising scientific and technical education, it was felt that more direct information was wanted on the subject, and the Government commissioned Mr. Edward Combes, C.M.G., M.P., President of the Board of Technical Education, to make inquiry with reference to technical schools and other matters connected with the systems of technical instruction in operation in Great Britain, and on the Continents of Europe and America. Mr. Combes' report was issued last year, and is a most comprehensive document. It is divided into two parts, the first of which treats of industrial art schools, and the second of technical training, and moreover has a number of appendices giving a considerable amount of useful information relating to technical education, both in this country and on the Continent. That on art is most complete, and enters very fully into the reasons why it should be taught, and the methods by which it ought to be taught. The different systems of art education are fully discussed, and the weak points in each pointed out. He gives credit to the various schools in England for having effected a very great change for the better in art designs, and points out to those who would disparage the work of the schools the fact that French monopoly of designing is at an end so far as British manufacture is concerned. Instead of going abroad for designs, foreigners, becoming familiarised with our advance in the industrial arts, are now continually coming to examine our system of teaching, to study our methods, and to avail themselves of the examples placed before the pupils at South Kensington and elsewhere. As an illustration of the altered relations between England and France, it may be stated that about five years ago one of the first manufacturers in Paris sent over to England for a collection of English designs in paper hangings, in order that his designers might avail themselves of them. For evidence of our advance in artistic culture, it is but necessary to consult those who are old enough to remember the changes of the last thirty years, and to hear what they say of the improved appearance of our shops and shop fittings, our warehouses and wares, our furniture and table appointments, our wall papers and carpets, our books and book bindings, our illustrated periodicals, and our children's toys and picture books. There is scarcely a household in the country that is not the better for the change, not a manufacture in which design has a place that has not felt its influences; and it would be altogether idle to deny that this advance, to be seen on every side, is greatly attributable to the schools of arts. The report gives a very good account of the different systems of art training in Britain and on the Continent, and especially of that followed out under the directions of the South Kensington authorities; and the evidence of Mr. Walter Smith, who was from 1871 to 1882 Director of Art Education in the State of Massachusetts, United States of America, is interesting, not only for the account it gives of the progress of American art teaching, but also for its criticism on the South Kensington methods. Mr. Smith is an Englishman, trained at South Kensington, and is likely to know the good and the bad points of the system there pursued; and we observe that he has the same objections that we have urged, viz., that the methods pursued are too mechanical, and do not train to originality. Mr. Smith said "he thought they begun in England upon a wrong basis—a very unphilosophical principle—and that they had been entirely misled by choosing that wrong principle. He had been misled himself, and until recently had made as many mistakes as anybody. He had only reproduced in his public work and teaching that which he had been taught, and there was not, in his opinion, one man who could be described as a thinker, or even as a great teacher, amongst all the men who started the schools of design. He did not think a single man amongst them would ever live in history as an educator." He then goes on to advocate a more intellectual system, and illustrates it by the work which is now being done in the Conservatory School of Fine Arts in Boston, of which he is now principal. We cannot enter into details of that, but we may say that the first part of the report gives one of the most interesting historical and descriptive accounts of art training which we have seen.

The part of the report on technical training is also most valuable, and gives an interesting record of opinions from different points of view, although we must confess that Mr. Combes is, in our opinion, too much inclined to rely on Government support, and he strengthens his position with statements like the following: "It is always asked how the State is to be paid for her expenditure in providing for this class of instruction. If the application of the saying that it is better to pay for a boy's education than to pay for his keep in prison is clear as regards general education, then much more is it apparent as regards technical instruction. The apprentices' municipal school costs Paris a large sum a year, and the working expenses also reach a considerable amount. The return to the city is made in the beauty of her fabrics, and has proved a good investment. The art and taste developed and applied in these schools give the city wealth and magnificence. Her workmen can design and decorate, carve and engrave, model and paint, in a way superior to others, and this has been obtained by means of art schools. It could not possibly be effected without them. Therefore the French are wise in their endeavours to keep the position Paris so long ago acquired—the mistress of the world as regards all kinds of art industry." But the report also points out that the professional schools of France resolve themselves into three types, the first of which is municipal, and is represented by the school of La Villette, the second by the school of Horologerie (clock and watch making) created and maintained by the trade or guild, and the third, that represented by the printing works of M. Chaix, and which is entirely maintained by those immediately interested, viz., the proprietors of the works and manufactories. It seems to us that we ought to observe a similar distinction in this country, but with greater strictness than is done in France. The subjects which are of common interest should be supported by public funds, either imperial or local; special trades schools should be undertaken by the employers and the employed conjointly through their organisations; while others should be undertaken largely by the masters as a means for educating their apprentices.

Our space will not allow us to enter into further details regarding the report, but we may say that it is one of the most complete and satisfactory which has yet been published; while if the recommendations which are made are fully carried out, New South Wales will soon be able to set an example to the mother country in the organisation of art and technical education.

FIRE AND LIFE RISKS IN AMERICAN ELECTRIC LIGHT INSTALLATIONS.

Fire risks in connection with electric lighting have been discussed by the Society of Telegraph Engineers and Electricians at their last two meetings, and in view of the general importance of the subject it will be interesting to our readers to learn the condition of affairs prevailing in this respect in the United States, as set forth in a communication we have received from an occasional correspondent in New York. Our correspondent writes:—

"In New York city the overhead wires of the arc lighting companies are rapidly deteriorating, and many of them should have been renewed at least three years ago. In most cases the leads used are of the kind popularly known as underwriters' wire, in which the covering consists of two or more layers of cotton braid, thoroughly impregnated with white lead paint. This wire has been so largely used on account of its low price, and the fact that the insurance companies' inspectors have approved it. The insulation, inferior from the first, is now becoming worse than useless. It has decayed, under the influence of sun and rain, until thousands of places may be found where the wires are actually bare of all covering. When the lines were first constructed, the joints were covered with so-called insulating tape. This article, while originally good, has been gradually cheapened under the stress of competition, until it has become worthless for the purpose for which it was originally intended. When new, it has sufficient adhesiveness to apparently insulate a joint; but the compound with which the fabric is saturated soon disappears through the action of the weather, and it hangs loosely from the wire, swaying in the wind, and giving a decidedly objectionable appearance to the lines. Perhaps the most serious phase of this state of affairs is the fact that the wires of other companies, harmless in themselves, come occasionally into contact with the arc light circuits, and are thus made the mediums of conveying destructive currents into locations where they are not looked for. Any repairer engaged in his ordinary line of duty may, therefore, be exposed to sudden and unlooked for dangers. When the agitation first began which finally led to the organisation of the Board of Electrical Control, a vast amount of nonsense appeared in the dally papers regarding the dangers of overhead wires. It was published in the interests of various underground schemes, but in a certain sense it was effectual. A large number of conduits have been laid, but so far there have been no means discovered by which electric companies can be legally compelled to place their wires into them. Although with the wires underground all danger will not be removed, it will certainly be diminished if the work is well done. Whether through ignorance or parsimony, there is, however, small prospect that electrical plant will be in future so erected as to be absolutely safe. Even with the best material, poor workmanship will nullify such intentions if they exist. Cases of careless work are very frequent. In one case a stranded conductor with an insulation of a rubber compound was twisted round a nail or hook, so damaging the covering that it was practically worthless. There are hundreds of 'wire butchers' engaged in this character of work who should be suppressed. The growth of the business has perhaps been too rapid to permit of the proper mechanical training of employés, and there are few competent instructors. Whatever control has been exercised over electric light installations may be traced to the authority of the underwriters, and yet their regulations are so exceedingly crude that the construction which complies with the rules of the Board in one city, would not be tolerated in another which happens to be under the jurisdiction of a separate organisation in the same line of business. Of course the laws of electricity are the same in New York, Boston, or Chicago, and the rules which are good in one city should be equally effective in another. An effort to rectify this condition of affairs in Boston has been made by the establishment of the New England Electric Exchange, the membership being made up jointly of insurance and electrical representatives. It is the intention of this exchange

Digitized by Google

to issue licenses to workmen engaged in wiring, and it remains to be seen if the organisation will effect the contemplated reforms. In New York city the underwriters claim to be satisfied with the existing conditions, yet there take place electrical fires in sufficient number to prove that the system of inspection is defective."

"The electric light companies here are not pursuing a sound policy. The loss of property by fire, personal injuries, and death, all tend to create a prejudice against electric lighting which should never have been allowed to gain a foothold. Now that cases of this kind are not only established facts, but appear to be increasing from week to week, instead of taking steps to prevent them, the companies endeavour, by statements before coroners' juries, and through certain electrical journals, to create the impression that the blame does not rest with them."

THE EDISON GLOW LAMP PATENTS.

Our last report on this case, in our issue of the 11th inst., terminated with the examination of Mr. J. Swinburne. Before his cross-examination was proceeded with, the Attorney-General stated that he was willing to admit that the carbon conductor in Swan's stick lamp had been made by Mr. Carré, in Paris, and that it had received its present form before carbonisation. It will be in the recollection of our readers that, in the former trial against Messrs. Woodhouse & Rawson, Sir Frederick Bramwell stated that, to the best of his belief, this carbon had been worked down from a thicker piece of carbon, and had not been carbonised in its present form, and in this opinion he was corroborated by the other witnesses for the plaintiffs. Mr. Swinburne was then further cross-examined by Mr. Moulton, with a view to show that if the material used in carbonising contained such a large quantity of sand as he had spoken of, the steam would have driven all the air out of the crucible before the temperature had been reached at which the air would begin to combine with the carbon.

Mr. Alexander Bernstein was then examined by Sir Horace Davey. He stated that he had sold large numbers of lamps in which the carbon was $\frac{1}{25}$th of an inch in diameter and from $\frac{3}{4}$in. to $2\frac{1}{2}$in. long, and that they were used in series with perfect success, both in this country and abroad, especially in the United States. When he went to America in December, 1880, he could find no Edison lamps on the market; but on visiting Mr. Edison at Menlo Park he found him making lamps with filaments of bamboo. On being cross-examined by Mr. Aston the witness mentioned one or two places where his lamps could be seen in use in this country, but declined to name any others. Mr. Justice Kay intimated that the witness's objection to do so was natural, as he was possibly afraid that Mr. Aston was laying the foundation for a case against him, and the matter was then dropped. This was the last witness called by the defendants on the scientific aspect of the case, the next witnesses giving evidence as to what they had seen in Newcastle at Mr. Swan's place of business during the years 1878 and 1879.

Mr. Proctor, a well known scientific gentleman, residing in Newcastle, who had been very intimate with Mr. Swan throughout that period, remembered Mr. Swan exhibiting a broken lamp to the Chemical Society of Newcastle on the 19th of December, 1878. This lamp was a good deal blackened on the inner surface; it had contained a small straight pencil of carbon, which had been ruptured. Mr. Proctor had analysed the black coating on the glass, and subsequently read a paper on his investigations. Mr. Proctor was also present at Mr. Swan's celebrated lecture on the 3rd of February, 1879, on which occasion the stick lamp was exhibited and incandesced for some time. It was worked from a dynamo and burnt steadily, giving a comparatively good light. Several hundred persons were present, and Mr. Swan explained the construction of the lamp. The witness then stated that during the summer of 1879 he had seen many lamps of various constructions at Mr. Swan's works in Moseley-street, some being made of paper and some of thread; and that he had seen some of these of an arched or horseshoe form, which must have been carbonised after they had received that form. These lamps were incandesced in Mr. Swan's works, and gave out 10 to 14 c.p. Mr. Proctor was cross-examined at some length by the Attorney-General for the purpose of showing that his memory was in fault, and that he saw these lamps in 1880 and not in 1879.

The next gentleman was Mr. Arthur Heaviside, the superintending engineer of the postal telegraphs at Newcastle. He had known Mr. Swan very intimately during the years 1878 and 1879, and had tested a number of lamps for Mr. Swan in the summer and autumn of 1879 for the purpose of ascertaining their resistance. The lamps contained thread-like burners in some instances, and in others flat strips of carbonised material bent into an arched form. The witness was able to fix the date of his tests by his notes of lectures delivered to a scientific class about that time. Mr. Heaviside was cross-examined at considerable length as to the accuracy of his dates, and stated that he had not only seen threads in a horseshoe form, but also with a double twist at the end of the horseshoe.

Mr. Patterson, who carries on business at Gateshead as an earthenware manufacturer, was then called, and stated that he had on several occasions before November, 1879, taken strips of paper, packed in powdered carbon, to be carbonised in his father's pottery furnaces; and he remembered Mr. Swan exhibiting his lamps in the workshop, and at the lectures, where he on one occasion assisted in fitting up the batteries. He left Mr. Swan's employment in January, 1880.

The next witness was Mr. Mayfield, of Queen Victoria-street, London, who had been the manager of Mr. Swan's scientific department until October, 1879. He corroborated the three preceding witnesses as to the experiments made by Mr. Swan in the autumn of 1879 with slender carbon burners. Several witnesses of minor importance were also called to speak to the same point, and this brought the defendants' case to its close.

Professor Dewar was then examined by Mr. Moulton, for the purpose of giving rebutting evidence on behalf of the plaintiffs. He stated that directions to enclose the filaments in powdered charcoal when carbonising were wholly unnecessary, inasmuch as persons with an ordinary amount of skill would know that this was desirable. He produced carbon filaments which he had made by carbonising in sand inside one crucible which he had placed in the carbonising chamber in the inside of another crucible, and stated that none of the filaments had been attacked by oxygen, and that he had actually made a lamp from a filament of broom carbonised in that way. Professor Dewar stated that there was no difficulty in rolling out a filament of lampblack tar, and he proceeded to roll one in Court to a very considerable fineness. He had mounted a filament so prepared in a lamp, and run it for a couple of hours. He had also rolled out filaments of lampblack, containing camphor and oxide of zinc, and carbonised them; but he had not mounted them. The witness also produced lamps in which the filament had been coated with silicate of soda and alumina. He had conducted several experiments with Despretz's process, the result being to completely disintegrate the carbon, owing to the very powerful currents used by Despretz; and he distinguished Despretz from Cheesbrough, because the latter pointed out that it was necessary to gradually increase the current during the flashing, which point Despretz did not mention. The witness stated that Cheesbrough's directions as to his alternative process, viz., impregnating lime with carbon, were not misleading, inasmuch as, if the carbon pencil surrounded with lime were put into the lamp, the lime cylinder would not crack off, and would do no harm. This witness was cross-examined at great length by Sir Horace Davey, and admitted that in his experiments on Despretz he had used secondary batteries, and obtained from them more powerful currents than Despretz used, and that the gradual increase of current was not essential in Cheesbrough, but only highly advantageous.

Dr. Hopkinson and Dr. Fleming were recalled to add to the evidence already given by them, the latter admitting that the plaintiffs had never made any lampblack and tar filaments except for the purposes of litigation.

The next witness was Mr. Joseph William Swan, who deposed that he had never made any thread lamps before November, 1879. He gave an extremely interesting account of his early experiments and failures. Upon cross-examination by Sir Horace Davey, he said his chief means of fixing any dates as far back as 1879 were letters which he had received from Mr. Stearn. He was then asked to explain how it was that he had been present during the trial against Messrs. Woodhouse & Rawson, in which the witnesses for the plaintiffs had repeatedly stated that, in their opinion, his stick lamp had been made by rubbing it down from a larger piece of carbon, and that he had never corrected them or mentioned the matter to the solicitors. Mr. Swan explained that he was not there as a party to the action, but merely as a person who had been subpœnaed by the defendants, and he did not then know that it was a matter of extreme importance in the action. Reports of many lectures delivered by Mr. Swan in the years 1880-1-2 were then read, in which Mr. Swan was reported to have stated that after a perfect vacuum, such as Mr. Crookes had produced, was created in the lamp, there was nothing more to be done except to perfect the details of the lamp. An affidavit was then read which had been sworn by Mr. Swan soon after the Edison Company attacked the Swan Company about the year 1882, and shortly before the two companies amalgamated and became the present plaintiff company. The words of one paragraph of that affidavit were as follow: "I believe that the said Letters Patent of the said Thomas Alva Edison are void, not only by reason of the prior publication of the invention claimed, but also on account of insufficient description." And finally two specifications of patents taken out by Mr. Swan in 1880 were put to him. In the first, he described the preparation of cotton thread by treating it with acid and carbonising it; in the second, dated five days later, he described and claimed precisely the same invention with this difference, that he used powdered charcoal in carbonising the filaments.

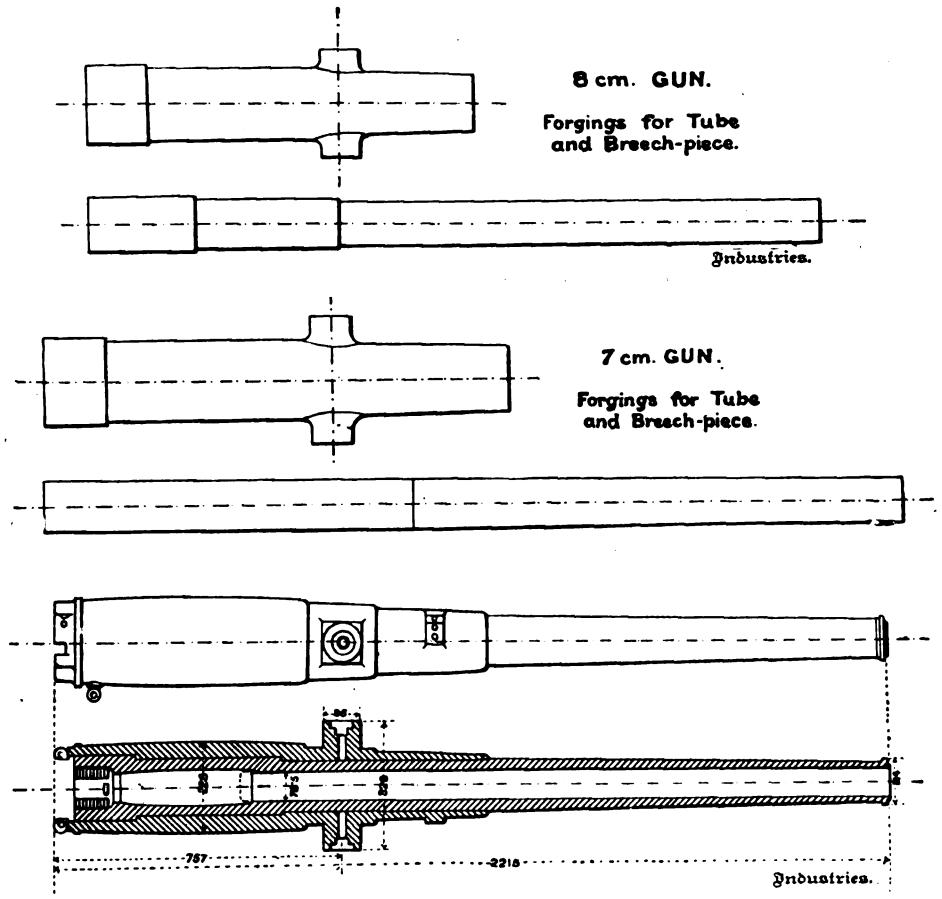
This brought the case to the end of the eighteenth day, when the Court rose for the Whitsuntide recess. It is understood that the plaintiffs propose to call further evidence, which will probably occupy another two days.

Letters to the Editor.

THE VALUE OF BOARD OF TRADE FORMULÆ.

To the Editor of "Industries."

Sir,—I have read with great interest your remarks upon the official report of Preliminary Inquiry No. 257 in your last week's issue. They are most opportune for my purpose, and singularly confirmatory of the position I took up in my letter of the 13th February with regard to the Board of Trade formula for the calculation of the collapsing pressure of fire boxes of vertical boilers, published in their "Instructions to Surveyors," and used in Report No. 145. In the letter to which I refer, published in your issue of the 17th February last, I drew attention to this formula, with special reference to its use in calculating the collapsing pressure of the fire box of a boiler of a steam crane that exploded at the West India Docks. This explosion formed the subject of Preliminary Inquiry No. 145—already mentioned—held by Mr. Peter Samson, and the result of the inquiry was to decide that the fire box, which was 4ft. high and $38\frac{1}{4}$in. and $40\frac{3}{4}$in. diam. respectively at the top and bottom, strengthened by two cross pipes 8in. diam., welded and flanged, placed at right angles to each other, made originally of $\frac{3}{8}$in. plate, reduced by corrosion on the fire side to $\frac{1}{4}$in. thick in places, but still with a remaining mean thickness of $\frac{5}{16}$in., collapsed from weakness, under a safety valve load of 49lb. per square inch.



By the Board of Trade rule Mr. Samson calculated the collapsing pressure of this fire box, taking the thickness of plate as $\frac{5}{32}$in., to be 106lb. per square inch, or 2·16 the normal pressure upon the safety valve. By the same formula, the collapsing pressure when new, taking the plates as $\frac{3}{8}$in., would be 141lb. per square inch. Mr. Traill remarked that "the strength of such fire boxes ought to be known by this time." I asked, "Would any competent engineer hesitate for one moment to subject a fire box of similar construction and dimensions to a test of that amount (141lb.) by hydraulic pressure?" and pointed out that if this formula was to be relied and acted upon, it would render a large reduction of pressure necessary. In fact, assuming the total number of boilers in the kingdom to be 150,000, upwards of 25,000—or taking the number of boilers at 140,000, as assumed by Mr. Thos. Gray, in his recent Memoranda to the President of the Board of Trade, about 23,300 boilers—would require alteration.

My object in now recalling these facts is to show from Report No. 257 that the remarks and statements I then made can be substantiated by the testimony and evidence provided by another Board of Trade inspector, Mr. James Ramsay. One or two curious inquiries also arise from the consideration of this report which are deserving of notice. It will be necessary to recapitulate a few only of the facts, as your summary of last week gave all the leading and necessary points. Suffice it to say that the fire box of the "Dolgelly" boiler was 6ft. 5in. high, 3ft. 11in. diam., made of $\frac{3}{8}$in. plates, single riveted and lap jointed, provided with three cross tubes, each 10in. diam., and that it was found collapsed on the right hand side nearly the entire height, with a rupture through the solid plate, 18in. in length and 3ft. wide. The Engineer Inspector states the collapse occurred because the fire box had suffered by corrosion, the plate at the fractured part being only $\frac{1}{4}$in. thick; and taking that thickness, "the collapsing pressure by Sir William Fairbairn's formula would be 175lb. per square inch, 2·18 times the working pressure, and 1·63 times the pressure per square inch to which the safety valve was loaded." With this remark, Mr. Ramsay dismisses the whole matter; no inquiry seems to have been made as to whether the boiler had been short of water, or the plates overheated in any way; and as you very pertinently observe, no reference is made either by the Engineer Inspector or the Engineer Surveyor in Chief to the collapsing pressure of the fire box by the Board of Trade formula. The Board of Trade formula did not suit the occasion, and it was not brought out and applied in this case. The inquiry naturally follows, Why? Simply because that to have done so would have been to show in the most conclusive manner its utterly worthless character, and how unreliable are conclusions based upon its use. As pointed out by you, the collapsing pressure of the fire box when new, and the plates of their full thickness of $\frac{3}{8}$in., would only be 107lb.; it ought therefore to have collapsed—if the Board of Trade formula was correct—the first time after it was set to work, and the steam pressure equalled the load on the safety valve of 107lb. per square inch. It was given in evidence that the ordinary observed working pressure was 80lb. per square inch; yet, as you also show, the collapsing pressure of the fire box by this formula was only 48lb.! Surely such an important fact ought not to have escaped the attention and notice of the Board of Trade inspector.

But there is still another singular feature to be noted. The collapsing pressure, by Sir William Fairbairn's formula, is not correctly given. The inspector's words are: "If the thickness of the fire box be taken at $\frac{1}{4}$in., the collapsing pressure by Sir William Fairbairn's formula is 175lb. per square inch," whereas the fact is that by that formula it is only 128lb. per square inch! How can such an error, if error it be, have crept into the report? It would have been awkward, to say the least, for Mr. Ramsay to have given correct particulars in face of his colleague's report No. 145. Mr. Traill's remarks are so ponderous and weighty that I almost fear to touch upon them, still I cannot help suggesting that if he had bestowed a little more care and thought upon the matter his "observations" might have had more value to the public, although possibly they might have lost their didactic and Tupperian flavour. For instance, it would have been most

STEEL FOR FIELD GUNS.

interesting if he had explained satisfactorily the cause of the absurd discrepancy which has been pointed out. Instead of mildly sneering at those not sufficiently informed engineers who have for so many years been making vertical furnace boilers according to the best and only information at their command, it would have been more useful and re-assuring if he had pointed out, what I think is almost self evident, that Messrs. Barrows and Stewart never intended this boiler to work at 107lb. per square inch.

The boiler was made according to the best practice and information available, and was well designed and proportioned, the bursting pressure of the shell and the collapsing pressure of the fire box being 268lb. and 313lb. respectively. Taking the usual factor of safety of 4, it would appear that the boiler had been originally constructed to work at about 65lb. per square inch, and that the owner and user, or some one acting for him, had ignorantly increased the load to 107lb., for which it was, there is little doubt, never intended. Had the boiler been worked at the pressure for which it was made, no explosion would have occurred. It would be well to have heard what Messrs. Barrows & Stewart had to say on this point, and it would have added to the value, as well as the fairness of the inquiry, if they had been asked and allowed to speak on their own behalf. By the ordinary formula, the collapsing pressure at the time of the accident, ignoring the presence of the cross tubes, would be, as I have said, about 128lb. There was, it is plain, therefore, no necessity to drag the special weakness of vertical fire boxes, as discovered by the officers of the Board of Trade, into the question of this explosion. It is a case of the simplest character, and is due to working a boiler that was made for 65lb. at a pressure of 107lb. It is, to say the least, disingenuous upon the part of the Board of Trade officials to omit all reference to the signal failure of their formula in this instance, and to suppress the fact that the boiler was being worked at one and three-quarter times the pressure for which it had, there is little doubt, been made. Rules made to affect the working pressure of from 23,000 to 25,000 boilers should be based on somewhat better and more extensive experiments than have led to the promulgation of the one under notice. Let us hope more care and prudence will be exercised in future. It would be well also if some careful revision of the official reports were practised before they are submitted to the public, as errors both of fact and judgment, such as appear in No. 257 alone, tend to shake confidence in their accuracy and usefulness, and certainly seriously reduce their importance and value in the eyes of well informed men.

Yours, &c.,

ECONOMISER.

Manchester, 19th May, 1888.

INSPECTION OF BOILERS.

A PAPER has been issued—containing memoranda prepared by one of the assistant secretaries to the Board of Trade on the subject of the registry and inspection of land boilers—which contains materials for the evidence to be collected and laid before the Select Committee on the Boiler Bill, which was to have been moved for by Lord Stanley of Preston in the House of Lords. In collecting and digesting the facts as regards boiler inspection in other countries, a distinction has been made between direct Governmental inspection and indirect inspection by societies whose guarantees are accepted by Government, and also purely voluntary inspection not prompted or accepted by Government at all, but originating in the necessity of a guarantee for purposes of insurance or in the desire of owners to omit no reasonable precautions for the security of their employés and their plant. Attention has also been directed to the degree of responsibility for accidents attached by the laws of the different States to boiler owners or attendants, and to the methods (if any) by means of which the efficiency of boiler attendants is secured. Some statistics are appended with a view to comparing the results of the different systems in use, and the method of inspection adopted by each country is shortly set out.

STEEL FOR FIELD GUNS.*

THE wonderful improvements that have taken place in metallurgy during the last thirty years having permitted great masses of steel to be produced with economy, artillerists and engineers now declare it to be the most suitable metal for the construction of guns. There are, indeed, some countries in which guns are still constructed of cast iron or of compressed gun metal, but this is due to economical rather than to technical considerations. In other countries the labours of distinguished artillerists have been directed to obtain from cast iron, wrought iron, and bronze, properties which have not been reached, and have delayed the universal adoption of steel for the construction of ordnance. This metal, the most admirable of all hitherto employed, is produced of so many descriptions, that it is necessary to fix the conditions it must fulfil when destined for ordnance purposes. Tenacity, ductility, a very high point of fusion, and a great resistance to the corrosive action of the products of the combustion of gunpowder, are the principal properties of a metal suitable for guns. The hard steels can satisfy the first condition; the milder steels the other requisites. Besides, it is of the utmost importance to know, by the deformations caused in the guns, when the destruction of the metal is approaching; and taking into consideration that certain elements of the gun, by the action of the powder gases, pass alternately from compression to tension, it is very easy to perceive why mild steel of mean tenacity has been adopted for the construction of ordnance. In the commencement of its use for this purpose, the quality of the material was only tested by its tenacity or breaking strain, without any definite standard for elongation. This was the practice followed in England, at least, until the year 1881, as stated in a paper read by Colonel Maitland at the autumn meeting of the Institute in that year. But the increasing requirements of the naval constructors and artillerists compelled the metallurgical engineers to improve the manufacture of steel, and they have accordingly undertaken the production of those enormous masses in the form of crank shafts for the powerful engines of Transatlantic steamers, or in the form of inner tubes for 110-ton guns; and if, in these enormous masses, the uniformity is not so great as in the small ingots, it is still probably sufficient. The steel for guns must be not only good, but of a superior quality, because the very great strains to which guns are subjected compel the constructors of ordnance to use a very high factor of safety, 12 tons per square inch being approximately the working stress of the metal. An eminent English engineer, Mr. Anderson, has proposed to use a factor of safety of $\frac{1}{4}$, in order to employ in the construction of guns a material of a more ordinary description; but I think it is better to have a superior steel, and to use a high factor of safety.

Having made these preliminary remarks, I am about to describe the manufacture and treatment of steel for field guns, as practised at the royal arsenal of Trubia. It is now our constant practice to define the steel for a certain purpose by its physical qualities, and more especially by its tenacity and ductility. Nearly all artillerists, in their specifications for steel, require, besides the tests of tenacity and ductility, that of bending by impact; but this test is not necessary, because, being only required in order to determine the presence of phosphorus, it can be suppressed without inconvenience, when there is security that the percentage of that metalloid is not capable of injuring the steel. At Trubia the characteristics of tension in the three states of the steel are the following, in tons per square inch:—

	Elastic Limit. Minimum.	Breaking Strain. Minimum.	Elongation. Minimum.
Annealed after forging	10·0	29·6	23 per cent.
High tempered	17·0	36·	16 ,,
Low tempered	14·0	32·8	21 ,,

The steel must be of a very superior quality in order to fulfil these conditions. Its manufacture takes place in the manner which I am now about to describe. The casting is made in crucibles, heated in the old well known furnaces. In my opinion the Siemens furnace is the best apparatus for casting steel intended for ordnance. Supposing the materials used in both processes to be of the same purity, it is possible to obtain more uniformity in large castings by the Siemens-Martin than by the crucible process; because, as is well known, the crucible does not improve the quality of the metal fused in it. The only advantage of this process is, perhaps, that there is no waste; but its great cost has led to the almost universal adoption of the Siemens-Martin process instead. Certainly the casting of a 60-ton ingot by the crucible process must be a wonderful spectacle if carried out with the marvellous and military precision of the celebrated Krupp firm; but this magnificent spectacle of course proves nothing in favour of the process. Its disadvantages are not so great in the casting of small ingots; and at Trubia we use it until the large steel foundry hydraulic presses for forging, and all the modern appliances, have been established. The materials introduced in the crucibles are the following: bar iron, worked three times; manganese ore, and charcoal—these two latter substances being introduced in the form of powder. The bar iron used is produced by the puddling of charcoal pig iron, made with the best ores of the Pyrenees and of Bilbao, which are only surpassed in purity by the finest Swedish ores. This pig iron, puddled in a Boetius furnace, gives iron bars of the greatest purity; because, as is well known, the hand puddling furnace removes 80 per cent. of the phosphorus, which goes into the slag; and as the pig iron has only 0·025 to 0·035 per cent. of phosphorus to begin with, we obtain bar iron with only 0·005 to 0·007 of that metalloid. The bars are subjected to careful selection; those which present a fibrous fracture at both ends are applied to the manufacture of steel. We are thus sure that the bars do not contain more than 0·35 of carbon. The selected bars are cut, piled, and rolled twice over, and at last a bar of $\frac{3}{8}$in. by $\frac{1}{2}$in. is obtained, which is cut in small pieces in order to be introduced into the crucibles. In this state the carbon of the bars is between 0·2 and 0·3 per cent. I think that the great ductility demanded in steel for guns, allied to corresponding tenacity, cannot be obtained with a simply carburetted steel, and that, in consequence, a manganese steel must be employed. At Trubia, manganese is not introduced as an addition of a certain quantity of ferro-manganese, but, as I have said, in the form of the ore of this metal, which is obtained as a very rich and pure peroxide from the mines of Covadongia, forty miles from Trubia. Its chemical analysis is as follows:—

Silica	1·30
Peroxide of iron	5·30
Red oxide of manganese	72·60
(Corresponds to the peroxide 82·76)	
Lime	3·60
Magnesia	0·80

The charcoal is employed for the reduction of the manganese ore, and the quantity introduced is no more than is necessary for making that reduction. The furnaces admit four crucibles; two with a charge of 72lb. of iron, the other two with 60lb. We have employed at Trubia, with much success, the Morgan crucibles; but now, as the system of public auction is adopted in Spain for the acquisition of materials, the Germans always offer crucibles more cheaply than the English, although English crucibles are certainly better than German. The crucibles employed in the melting of steel for guns must have made one fusion, because in this first fusion the plumbago contained in the crucibles is removed, and there is then no risk that any quantity can be incorporated into the steel. English condensed coke of the highest quality is the fuel employed in the furnaces, and 3·2 tons are required for the production of one ton of steel. The time of melting varies from four and a half to five hours. When the steel is completely fused, the crucibles are carefully excoriated before removal. The slag, which is a very acid one, is a double silicate of manganese and iron. I will not describe the process of casting the ingots, which would be very tedious. I need only say that the jet is always proportional to the section

*Paper read by Captain L. Cubillo, Spanish Artillery, Ordnance Works' Trubia, before the Iron and Steel Institute, on the 10th May, 1888.

Digitized by Google

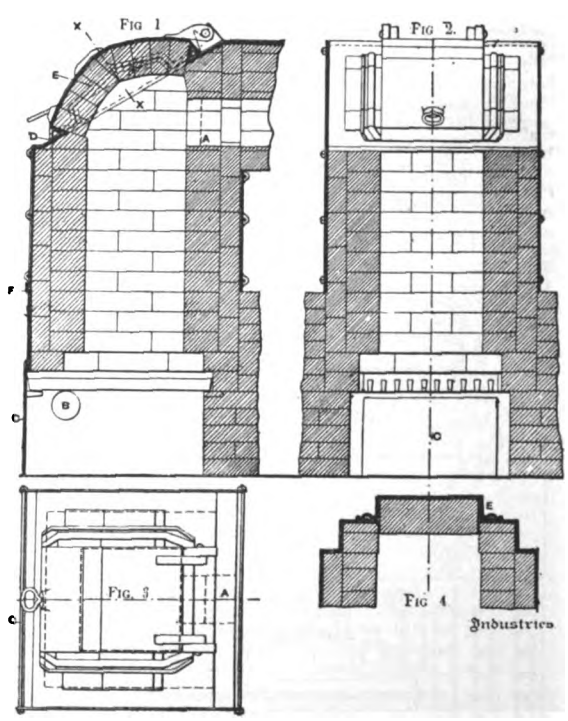
of the mould. Ninety men are necessary for the casting of the 3-ton or 2-ton ingots. The moulds employed have a circular section, and we have given the preference to this form in order to avoid the plans of less resistance originated by the crystallisation of steel in the polygonal moulds. These have a quadruple section like that of the forgings, a relation which permits of sufficient work under the hammer for obtaining a fine and amorphous texture. I think, however, that with the work put upon the metal by the forging process, the mild steels for ordnance purposes do not acquire the best molecular conditions; and that this best condition is only possible after two or three temperings at different temperatures. I intend to develop this idea when speaking of the tempering process; but at present I will follow the order of the operations. The cold ingot is taken out of the mould and carried to the mechanical shops, where both its ends are cut; the top with a weight of 35 per cent. of the whole ingot, the bottom with 5 per cent. Besides, its outer part is rough turned until the cavities situated in the periphery may have entirely disappeared. With these operations two very important objects are attained, viz.: First, by the previous cutting of both ends of the ingot, the distribution of the cavities is ascertained; because sometimes, when the casting has been badly carried out, there is a great number of them in the inner part of the ingot, and then this is rejected. Second, by the total disappearance of the cavities, the ingots are forged as sound as it is possible to obtain them, taking into consideration the methods of melting and casting employed, and the actual state of metallurgical science. In the new steel works to be erected at Trubia, a powerful hydraulic press for the compression of the metal while in a fluid state will be installed, it having been ascertained that the cavities of the ingots are due to the absence of pressure. It has been my good fortune to witness this process at Sir Joseph Whitworth's works, and I am convinced of its beneficial results. The chief object to be attained by the forging process is the change of texture of the ingot, making it to pass from the crystalline to the amorphous condition. At Trubia, the rules given by Tchernoff for the heating and hammering of the ingots are carefully followed. These are heated to a temperature of 1980 degrees, and returned to the furnace when the temperature has fallen to 1260 degrees. The ingots hitherto forged having been of relatively small dimensions, and the re-heating furnaces being very large, it has been possible in each heat to have within the furnace the whole of the ingots; and by this means we have entirely avoided the dark lines which separate the heated parts of the ingot from that which is out of the furnace. It is evident that this system cannot be practised with large ingots, because it would be necessary to employ furnaces of colossal dimensions. The ingots are at present forged under the steam hammer; but as I have said, in the projected new steel works large hydraulic forging presses are to be installed. The ingots are heated in a Boetius gas furnace, to which I have applied, as far as possible, the principles of heating by radiation, as described by Mr. Frederick Siemens in his admirable paper read before this Institute at the Chester meeting—that is, the roof of the furnace has been elevated, free space has been allowed for the perfect combustion of the gases, and the contact of the flame with the walls and roof of the furnace has been prevented. In conducting the heating of the ingots in this way, the advantages attributed by Mr. Frederick Siemens to this process, viz., less waste, and the greater duration of the furnace, are fully confirmed. Sometimes it has been necessary, during the forging process, to "scarf" some ingots which presented cracks due to the steel being harder than usual, and having been heated to the same temperature as mild steel. The first heat for the 16in. ingots lasts for four hours, and that for the 20in. and 24in. ingots for five or six hours. When the forging is completed, the ingots are covered with ashes until they become completely cold.

The steel, the manufacture of which I have now described, has a chemical composition varying within the limits of the two following analyses:—

	Mn.	C.	Si.	S.	Ph.
First.....	0·32	0·23	0·05	traces	0·005
Second.....	0·38	0·33	0·06	nil	0·007

The cold ingots are carried to the mechanical shops, where they are rough bored and turned; and when these processes are ended the mechanical tests are applied. At first the test pieces were cut lengthwise of the ingot; but taking into consideration that the most convenient course was to know the state of the metal in the cross section of the ingots (because in these sections the two most important forces originated by the powder gases exist), the test pieces are now cut crosswise of the ingots. At Trubia, in each condition of the metal—*i.e.*, when annealed after the forging, and when high and low tempered—one slice is taken from both ends of the tubes, and in each slice three test pieces in the direction of the sides of an equilateral triangle are cut. In order always to obtain comparable results, the dimensions of the test pieces obey a law, which is expressed by the following equation: $L^2 = 50\ S$; in which L represents the length for measuring the elongation, and S the section of the test piece. The same equation is employed at the celebrated Creusot steel works. This is a most important matter, because it is possible to obtain different results, with the same metal, by changing one of the dimensions of the test piece. At Trubia, the Thomasset testing machine, improved by Colonel Maillard, of the French Naval Artillery, is used; its power is 60 tons. The elongation is measured by an apparatus called the "Dumoulin-Iroment Cathetometer," which indicates to 0·0002 of an inch. The tests are made with the most exquisite care, viz., the elastic limit, the elongation, the breaking strain, the elongation after breaking, and a final test, which it is very important to know—the correspondent to the strain with which the striction of the test piece commences. This elongation is independent of the length of the test piece. Even when the Maillard testing machine behaves very well, I think it is preferable to use the autographic machines constructed by Messrs. Buckton & Co., of Leeds, which indicate, as a final result of the testing, not only the elastic limit, the breaking strain, and its respective elongations, but also the work done upon the metal. It would be very convenient to adopt the work described by Poncelet as "*travail de resistance vive de rupture*," as the measure of the resistance of a metal. It is clear that if this method were adopted in dealing with steels for ordnance purposes, it would be necessary to fix the minimum breaking strain; because the elongation, being preponderant in the value of work, the extra mild steels, which are not suited for the construction of guns, are capable of producing more work per square unit than any other. I think that the quantity of work made by a steel, in each of the states of annealing and tempering, cannot be augmented or diminished by the manner of applying the strain—that is, it can happen that a steel test piece, subjected to a tensional dynamic strain, may break with an elongation greater than that acquired when submitted to successive static strains; but if this happen, undoubtedly the dynamic tensional strain must have been less than the static tensional strain. This is, in my opinion, the only interpretation of the experiment stated by Colonel Maitland in his paper read before the Institution of Civil Engineers on the 15th March, 1886, in which experiment a certain steel, which was submitted to static strains, broke with an elongation of 27 per cent., and when subjected to dynamic strains, broke with 47 per cent. It will be convenient, before describing the tempering process, to demonstrate its necessity. At first sight it would seem that if it were possible to produce, by forging only, a steel with the conditions demanded for gun purposes, the tempering process, which requires a very large and expensive plant, might be avoided. Nay, if the object attained by this process were only that of the increase of the tenacity of the metal, with a corresponding diminution of its ductility, a simple variation of the chemical composition of the steel would give the same result as tempering. The chief object sought to be obtained by tempering at different temperatures, is the uniform distribution in the ingot of the various substances which compose the steel, and more especially of the carbon. The new steel cellular theory by MM. Ormond and Werth, which appeared in *Les Annales des Mines*, Vol. VIII., 1885, and of which, in my opinion, Professor Akerman's admirable paper on "Tempering Iron and Steel" is the base, explains in a satisfactory manner the changes that occur in steel when passing from the forging to the tempering state, changes which are indicated by its mechanical qualities. The foundation of the Akerman theory, in explaining the phenomena of tempering, which has been accepted by the authors of the cellular theory, is the following: The combined carbon is present in the steel in two forms; the carbon more intimately combined, called tempering carbon, and the carbon incompletely combined, described as cementation carbon. If a steel ingot is heated between the points A and B of Tchernoff's scale, and is quickly cooled, the more the part of the total carbon will be converted in tempering carbon, the more may be the temperature of the ingot, or the more quickly the ingot may have been cooled. Now, if the same ingot, whose percentage of combined carbon has been increased, is again heated to a temperature lower than the former, and is also cooled under the same conditions, a certain part of the incompletely combined carbon, converted in tempering carbon by the first operation, recovers its primitive state; and this last change is manifested in its mechanical qualities by a diminution of tenacity and an increase of ductility, so that this second tempering, as compared with the first, has all the appearance of the annealing process. At first sight it would seem that if the temperature of the second tempering is very low, the metal should return to the conditions resulting from being annealed after forging, and then a great amount of time and money would have been wasted. But that is not the case; for, by the second tempering at a low temperature, the carbon incompletely combined is distributed throughout the mass of the ingot in a more uniform manner than by the first. So, at Trubia, after the second or third tempering, we have generally observed that the characteristics of the steel had improved as compared with those possessed by the metal when annealed after forging. I quote the following example, which, I think, is very remarkable:—

Tube A for a 3·5in. gun.	Elastic Limit.	Breaking Strain.	Elongation per cent.
Annealed after the forging...	10·64	20·76	25·85
(1) Tempering at 1620°.....	30·00	51·00	15·15
(2) Tempering at 1260°.....	21·00	40·76	20·2
(3) Tempering at 1080°.....	16·7	36·18	27·3



It has been observed in many cases that two low tempers at the same temperature improve the metal considerably. I am now about to explain the manner of practising this process. As I have said, each tube or breech piece is tempered at least twice—the first at a high temperature, about 1800 degrees; the second at a temperature between 1080 degrees and 1260 degrees. If, with these two temperings, the steel has not acquired the characteristics required, the tube or breech piece is tempered again, the temperature being raised or lowered as required by the results of the test pieces, which are cut at both ends of the tubes after each tempering. It is well known that the temper which a steel of a certain chemical composition can take depends on the following factors, viz., the temperature of the metal, conductibility, specific caloric, and quantity and temperature of the cooling medium. At Trubia, as is the case in all steel works, the cooling liquid employed is the oil which, by its small conductibility, produces tempers less energetic than water, both liquids being at the same temperature. The tubes and breech pieces are always tempered in a quantity of oil equal to ten times the weight of the piece tempered. The heating furnace is vertical; its temperature is carefully measured by a Siemens pyrometer, and the tubes are taken out of the furnace and immersed in the oil tank by an overhead travelling crane. Lately, at the "Acieries de St. Etienne," this method of tempering has been changed, by making a stream of oil to pass through the tube. The advantages derived from this method are that the thin cylindrical films of which the tube is composed acquire the best condition for resisting the pressure of the powder gases—that is, the exterior is in tension, and the interior in compression; and the tube, as tempered, can then be assimilated to a series of the thinnest cylinders shrunk on. The method is not a new one; it was invented by the late Major Rodman, U.S.A., for strengthening cast iron guns; and in the opinion of Sir William Siemens, is more applicable to steel than to cast iron. I think that the system of St. Etienne must be adopted, if conducted as Rodman practised it—that is, cooling the interior of the tube, and heating the exterior. Experiments in this direction are about to be commenced at Trubia, and another is to be directed to investigate the possibility of tempering with hot water by the ordinary method, or with water at the ordinary temperature, but in less quantity. In this last case, the experiments must be directed to investigate the caloric conductibility of both liquids; and this point obtained, it will be very easy to calculate the quantity of water, at the ordinary temperature, which may take out of the steel the same quantity of heat in the same time as a weight of oil equal to ten times that of the tube to be tempered. After the tempering process, the only caloric operation practised with the tubes is the shrinkage, which offers little interest, considered from a metallurgical point of view.

In concluding this paper, I must add that the field guns constructed at Trubia have been designed by Major Sotomayor, of the Spanish Artillery, a member of this Institute.

KEEP'S TESTS FOR FOUNDRY IRON.*

All who have had to do with the testing of cast iron are aware of the fact that hitherto there has been no uniform and recognised system of tests applied in order to determine the mechanical characters of the material. Not merely do the tests applied in different countries vary considerably, but the methods used by the scientific experimenter are often widely different in character from those adopted by practical men; and even in the same locality founders and engineers differ considerably in regard to the tests they require for irons to be used for the same purpose. The present paper is written to introduce to the attention of iron founders and engineers in England an attempt to find a common language to be applied in speaking of foundry iron. The apparatus and methods to be described are intended to be as simple in construction and operation as possible, so as to meet the requirements of the practical founder, and at the same time to be of such accuracy as to meet all the ordinary requirements of scientific research. It may be mentioned at the outset that the tests recommended are the result of many years' experience in working with various classes of iron from widely different localities, and that they have been successfully adopted, without any important alteration, for upwards of two years at the works of the Michigan Stove Company at Detroit, Michigan, U.S.A. (of which company Mr. Keep is superintendent), where upwards of 70 tons of pig iron is daily manufactured into thin castings. "Keep's Tests" have also been adopted by a number of important American firms who have to do with the buying and selling of foundry iron.

Re-Melting.—It is desirable to have at least 50lb. of the iron which is to be tested. It is possible to perform the tests with 15lb. or even as little as 10lb. of metal; but it is desirable to retain sufficient for two further meltings, in case a duplicate test is required at any time. The 15lb. of metal is melted in a plumbago crucible of suitable size, and of such a kind as is commonly used by brass founders. The bottom of an old

crucible may be used to cover the pot during melting. The furnace employed by Mr. Keep is shown in Figs. 1 to 4, and will need little more explanation than is embodied in the illustrations. This furnace is of fire brick, coke is used for fuel, while the furnace is driven by a fan producing a pressure of blast of 2½oz. per square inch. The iron will be melted in about thirty-five minutes, and will be changed slightly, if at all, from the original composition. It is important to remember that the object of the tests to be described is primarily to determine the characters of the pig iron, and hence it is necessary that the change produced by melting should be as small as possible. Melting in a cupola, or even in an air furnace, would, of course, produce considerably more change. The furnace may be partly above the floor, or wholly beneath it, as found most convenient. The ash pit must be air tight, and the furnace itself must be tight, so as to exclude air, and prevent flame blowing through the cracks. The most refractory material must be used for lining, and ground crucibles,

* Paper read on the 24th March, before the South Staffordshire Institute of Iron and Steel Works Managers, by Mr. Thomas Turner, Assoc.R.S.M.

with just enough fire clay wash to bind it, is best for repairing. Before describing the tests in detail, the annexed table may be referred to as illustrating the results obtained with a particular sample.

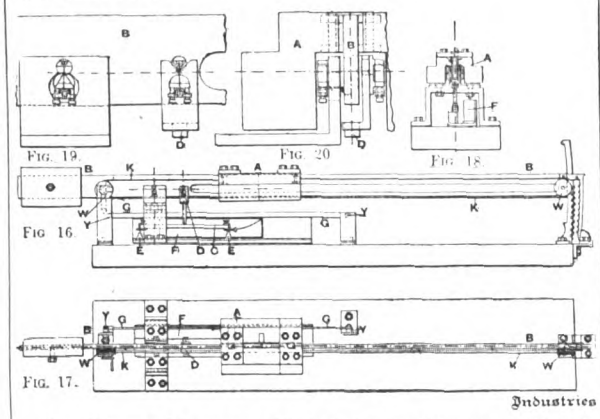
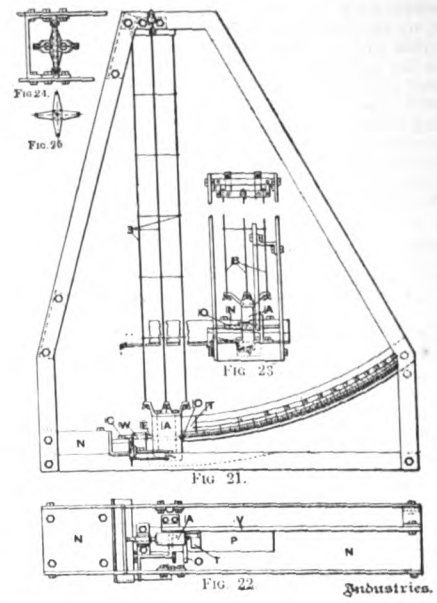
Industries.

Test Bars.—These consist in the first place of two bars, one exactly half an inch in square section, cast with the ends against a chill exactly 12⅛in. apart (see Fig. 5); the other bar is cast with this, and is run from the same gate; it is 1in. wide and $\frac{1}{10}$th of an inch thick, and is run against chills in the same way as the square bar. Six of these pairs of bars constitute a test, and each bar bears the number of the chill against which it was cast. When the bars are trimmed, and both bars and chills have attained the same temperature, the shrinkage of both thin and square bars is measured to $\frac{1}{2000}$th of an inch by inserting a graduated wedge (Figs. 11 to 13) between the end of each and its chill. The mean between the shrink measured on the two ends constitutes the shrinkage. The transverse strength and resistance to impact are measured as afterwards described. It may be mentioned, however, that the transverse strength is obtained by breaking square bars 1, 2, and 3 by means of a gradually applied weight, the deflection being measured at the same time. Bars 4, 5, and 6 are then broken to obtain resistance to impact by a series of blows from a 25lb. weight, the first blow being with a half inch fall, and the fall increases by $\frac{1}{8}$ of an inch each time. An arbitrary scale has been constructed, giving a value in pounds avoirdupois on an assumed value for a foot-pound. This has been done in order to allow of comparison between the effects of a weight gradually and suddenly applied. After these have been determined, the broken bars are used for observing the depth of chill and the character of the grain, both of which are recorded for reference. The depth of chill is determined by splitting off the end of a square bar longitudinally by means of a cold chisel, and measuring the depth of the chilled metal. The grain of the fracture of the bar is observed by means of a pair of lenses, each of 1¼in. diam., and 1in. focal distance. The focal length together is ½in., and with a little practice this gives a clear view. In addition to the bars above mentioned, two other test pieces are made. The first is called a fluid strip, and is intended to indicate the relative fluidity of the molten metal. The pattern for this is 1in. wide, 12in. long, and $\frac{5}{10}$ths of an inch in thickness. This is run from the end and is poured first. This strip rarely runs full, and the length of the strip in inches is taken as a measure

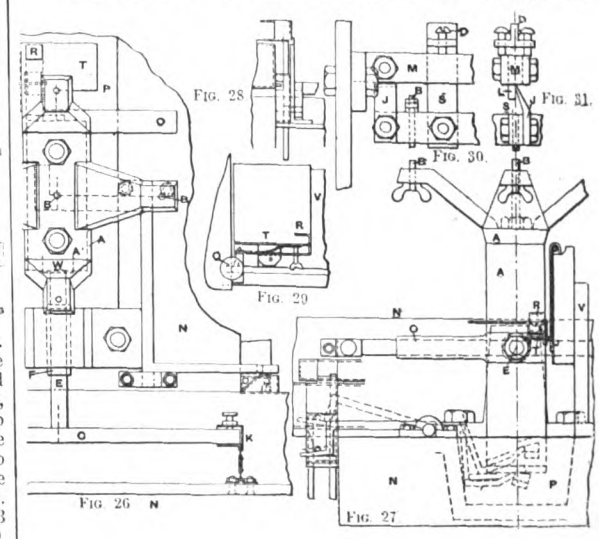


of the fluidity of the metal. It is, of course, necessary for this test that the metal should always be poured at about the same temperature, and, with a careful workman, the test gives fairly uniform results with given brands of iron. The second of these test pieces is called the crook strip; this is 12in. long, 1in. wide, and $\frac{55}{1000}$ths of an inch in thickness. On the centre of one side there is a rib $\frac{412}{1000}$ths of an inch high; this is ⅛th of an inch wide at the base, and $\frac{1}{10}$th of an inch wide at the top. The unequal shrinkage of the thin, flat strip, and of the taper rib, causes a slight curve in the test piece. This, when measured, affords valuable information as to the properties of the iron, and is called the "crook."



Patterns.—These are fully shown in Figs. 5 to 15, and need no detailed explanation. The follow board is of iron, and everything is made with the idea of durability, and no appreciable wear should take place. No change should be made in the patterns after beginning to use them, as a change might alter some important condition.

Moulding.—This is done with such sand as is used for light castings, and which has been used before, but to which no facing has been added, neither should facing be used in preparing the castings. Enough sand must be tempered overnight to do the work of the day without using any sand over again. The flasks used are of iron, very carefully fitted; the inside measure is 14½in. by 7½in., the nowel is 1in., and the cope 1½in. deep. An iron weight is used on the top instead of clamps. No rapping is done to cause the pattern to leave the sand, and the casting must be like the pattern. The iron is poured from the crucible as soon as it is skimmed; the first flask contains the fluid and crook strips, which are poured before any other. The remaining six flasks are poured in order of their numbers.



Measuring Table.—The measuring table is mounted on a box or table, so as to be of a convenient height, and is an exact duplicate of the follow board (Figs. 5 and 6). On the front of this iron table (Fig. 5) is the measure for crook strip. The strip is slipped behind the springs M, with the nose of its rib against the straight edge V. The measuring wedge (Figs. 11, 12, and 13) is then slid down the slot V′ in the straight edge. This slot is exactly $\frac{1}{1000}$ths of an inch deep, so that the 100ths wedge (Fig. 12) may be used, and the record, which is the correct crook of the strip, is, of course, $\frac{100}{1000}$ths less than the reading on the wedge. This allows the small wedge (Fig. 13) to be dispensed with, as the shrinkage of iron never runs so low as one hundred, and is rarely higher than 250. It is well to break the ends of the crook strip and record the appearance of the grain. To measure the shrinkage of the square and thin bars, the iron table has steady pins so arranged that the chills and the bars will lie exactly as they did in the mould. In Fig. 5 steady pins are shown on the sides of the thin bar; these are necessary on the measuring table, but are not required on the follow board used in moulding, as the steady pins Z and Z′ on the gate hold the pattern in the same position as the pins hold the loose bars. Openings are made through the iron table, between the ends of the bars and the inside of the chills (see dotted lines I I′, J J′, &c.) so as to allow a measuring wedge to be inserted. The actual measurement is conducted as follows: A chill bearing a certain number is laid in position on the table, and the castings are selected (both square and thin bars) which bear the same number as the chill. The right hand end of the square bar is pressed against its chill, the wedge is then slid between the left chill and the end of the bar, and the reading taken. The operation is repeated at the other end, and the mean of the values obtained is recorded as the "shrink." The bars and chills are marked on their ends to show how they lay in the mould, and the experiment is performed first with the upper corner, which is called the cold edge, and is afterwards repeated with the hot edge of the square bar. The hot and cold edges of the thin bar are then treated in the same way. One of the thin bars should be broken, in order to record the appearance of the grain to the naked eye. There still remains to be described the details of the two machines adopted for testing the strength of the square bars.

The Weight Machine.—The test bar used being exactly 1ft. long, and the bearings being exactly 1ft. apart, the ends of the bars are clamped in small extension pieces made of tempered steel. These may be of any convenient form (see Figs. 16, 26, 27, and 34). If a blow hole or a flaw exists in any bar a clamp is placed over the defect (Figs. 14 and 15). A plate carrying the supports for the bar is placed on the bed plate of the machine, so that the test bar shall come exactly under the beam of the machine, and the centre of the bar under the pressure post D. Figs. 16 to 20 show this machine. It consists of a beam B moving on a knife edge which is shown fully in Fig. 19. Forward from this 1 decimetre is another knife edge which transfers the weight to D. A saddle A, weighing 50lb., travels on the beam B, its centre of gravity corresponding with the knife edge when its weight is pulled to the near extreme. The beam is balanced by a weight, so that when A is clear back it exerts no weight on D. When the weight is over D it exerts a pressure on D of exactly 50lb., and each forward motion of a decimetre adds a pressure of 50lb. The capacity of the machine is 600lb., which is more than is required for cast iron. The perpendicular rise of D is half an inch, and it begins at its upper limit, so that the breaking of the test bar shall be when the beam is near the horizontal. The wheel W is turned by means of a crank, and thus moves the steel cord K, which carries with it the weight A. On the same shaft is another smaller wheel Y, which carries another steel cord G, which moves in the same direction, but only over one-fourth the distance. This cord is employed to impart motion to a portion of an automatic arrangement for recording the deflection. To this cord G is attached a board, which moves with it, and on which is fastened a sheet of paper. Attached to the under side of the beam, at a point 5 decimetres forward from the knife edge, is a pencil whose point is pressed against the paper. By this arrangement the deflection is multiplied five times, and is recorded on the paper. The weight is also recorded at the same time; but as the board moves only one-fourth of the distance traversed by the weight, and as 1 decimetre on the large beam corresponds to an alteration of 50lb., it follows that on the diagram 50mm. represents a weight of 100lb. The use of steel ribbons to hold the knife edges on their bearings does not detract from the sensitiveness of the machine. At the forward end of the machine is a series of steps, and attached to the end of the beam is a dog, which, by means of a spring, allows the beam to descend without friction while the machine is weighing; but the instant the test bar breaks the dog drops into the next step and remains there. For foundry practice this is all that is required, and, if preferred, the weight can be read from the upper graduated edge of the beam. For more accurate work a "recorder" is used (see Figs. 32 to 34). In this machine nearly all the parts are of sheet metal, and by means of a parallel motion the pencil is caused to describe a perpendicular line.

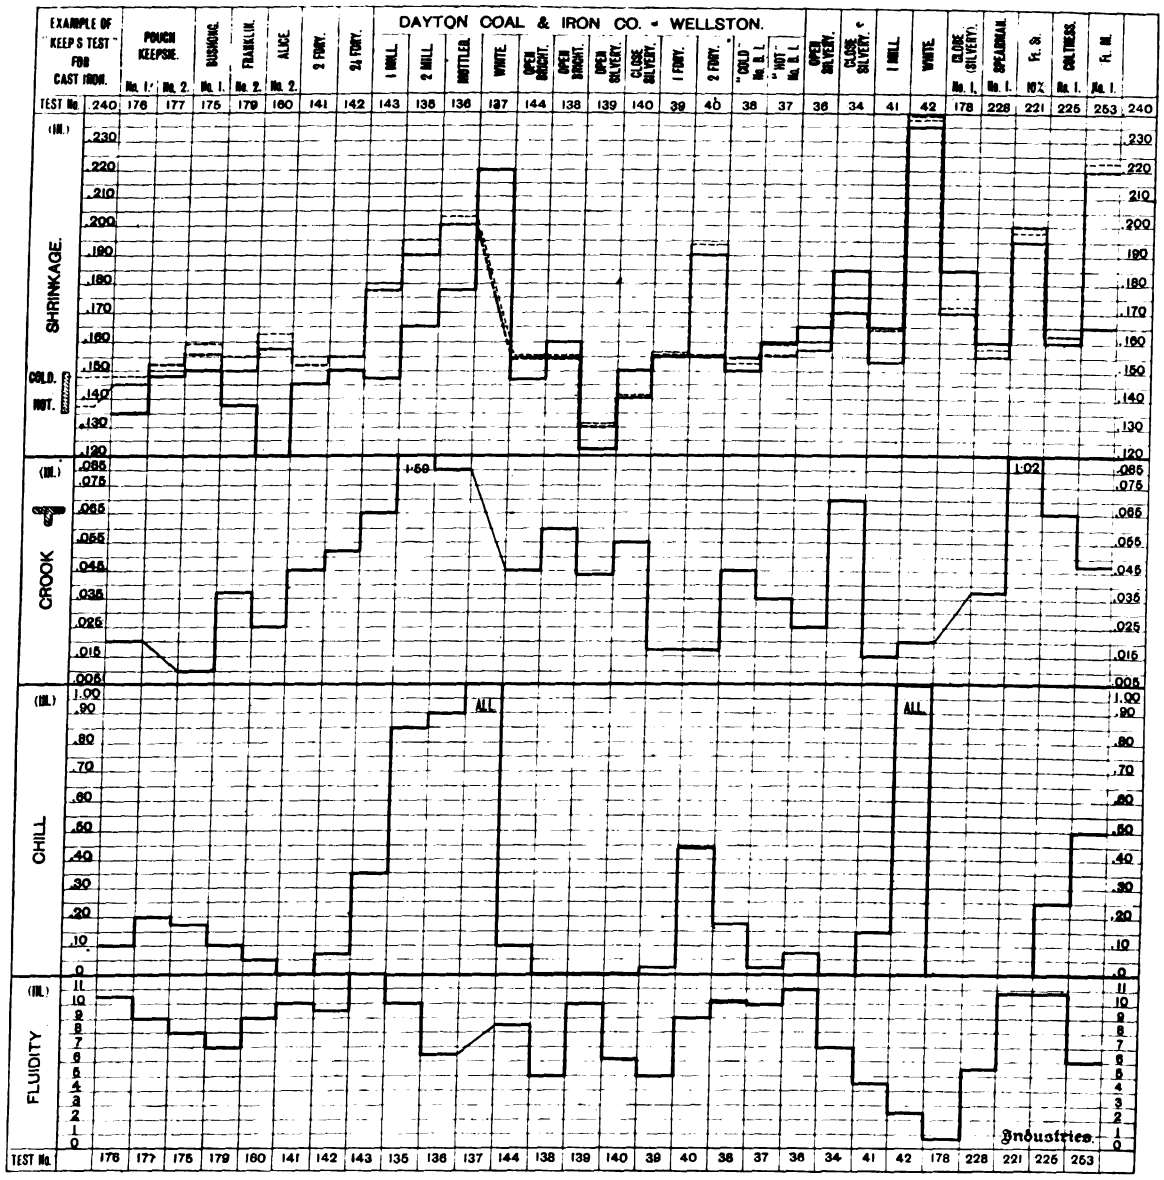
The Impact Machine.—This has a bed plate exactly the size of the weight machine. An iron frame carries sockets at the top which support a swinging weight A of 25lb. The radius arm has a ½in. steel centre strut, and four steel ties, each $\frac{3}{16}$in., forming with the webs B a rigid and very light trussed rod. The bed plate and frame and anvil N form a resistance much in excess of that actually required. The test bar is set on supports just as in the weight machine; but for accurate work the recording device, previously referred to, is used. The weight A is raised by means of the operator's left hand, the handle O being held until the catch T takes hold of it. By pressing a trigger the weight A is released and delivers its blow through the

steel hammer W upon the light hollow slide E, which rests directly on the bar—or in the cage of the recorder if this is used. The blow is thus communicated to the centre of the test bar. While the weight is swinging and delivering its blow the operator moves the catch T up to the next ⅛in. notch, so that each blow is delivered ⅛th of an inch higher than the preceding one. The first blow is always struck from ½in., and each succeeding blow increases by ⅛th of an inch. Only the blows which produce permanent set appear to materially influence the bar, and therefore, by beginning at ½in. (which is lower than the weakest foundry iron), all bars receive as nearly as possible the same treatment. The fall of the breaking blow is shown by the position of the catch on the scale when that blow was struck, and a reference to the table, previously given, shows the value of the blow in lbs.

Hardness Tests.—Hitherto it has not been possible to determine the comparative hardness by any scientific method. This is now done by means of a Turner's "hardness" machine. The test bar to be operated upon has its fractured end polished to a standard surface; it is set under a diamond of a standard cut, and the diamond is weighted until it produces a scratch similar to a standard scratch. The hardness of the bar is expressed by

Digitized by Google

KEEP'S TESTS FOR FOUNDRY IRON.



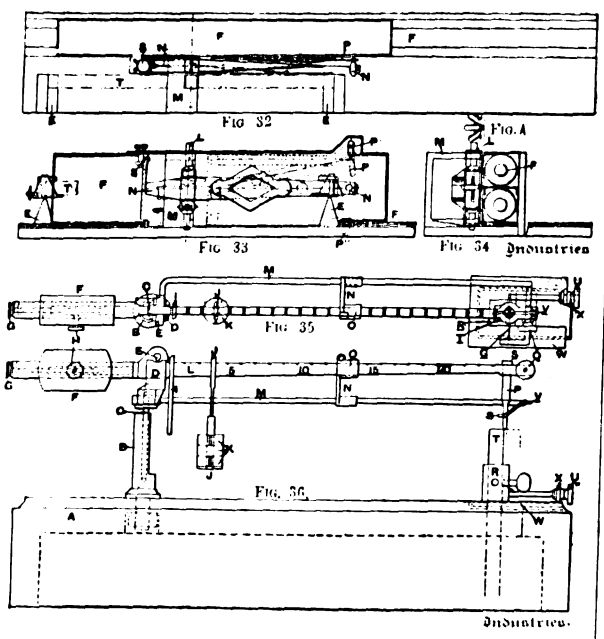


FIG. 37.

the number of grammes necessary to cause the diamond to make this standard scratch. Figs. 35 and 36 show such a machine, which embodies some improvements due to Mr. Keep. When there is no weight on the machine the beam is perfectly balanced. The weight carrier and the weights are each exactly 25grm. In testing cast iron it is usual to commence with the carrier and

three weights; it will be seen, therefore, that as there are twenty-five equal divisions each notch adds 4 grm. Intermediate values are obtained by such different use of the weights as may be necessary. To lessen the chance of the operator varying the scratch in using the instrument in the ordinary way, an arm (not shown in the illustration) is attached directly to the centre pin, and to the end of this arm is attached a silk thread. This allows the diamond to move freely up and down, while it is pulled laterally on its point. The maximum variation in the hardness of cast iron, as given by the above tests, is from about 22 to 72, the latter value being observed in specially hard white iron. The annexed charts (Figs. 37 and 38) give the results of physical tests of a number of American irons referred to in our previous paper. There are also added tests of English 10 per cent. ferro-silicon, No. 1 Coltness, and of specially pure Swedish grey iron (FL M). We cannot enter into a detailed discussion of the results at present; but it will be sufficient to say that an examination of these results show that the application of new methods of testing has opened up quite a field of important questions as to influence of various elements, such as graphitic and combined carbon, silicon, sulphur, phosphorus, and manganese on the shrinkage, chill, crook, and fluidity of the metal. When it is also remembered how much has yet to be done in connection with power to resist a force, either suddenly or gradually applied, and with the deflection of cast iron, we should feel that, in many respects, our knowledge of cast iron, from a scientific point of view, is comparatively in its infancy. If Mr. Keep has by these tests merely indicated some of the points upon which we are at present ignorant, and given us new ideas in connection with methods of investigation, he will have rendered us no mean service. Mr. Keep is at present continuing his tests, and with the assistance of Mr. Fleming, who performs the chemical analyses, hopes at some future time to give an account of the influence of various elements on the properties of cast iron. Mr. Keep has already conducted a series of experiments on the influence of silicon on cast iron, and his results, though bringing out new and interesting matter, substantially support the conclusions arrived at by Mr. Turner. It is probable that some exception may be taken to the size (½in.) of square test bar recommended in this paper. In connection with this Mr. Keep's views are as follow:—

It will be granted by all practical men that no one size of test bar can show the character of metal we may expect in all sizes of castings. A bar must be of such a size that the mould will not alter the character of the metal more than would occur in actual practice where castings are of all sizes. Many castings are only ½in. in thickness, while very much iron is cast thinner than this, and the thinner the castings are the more is the skill necessary to produce a soft, strong iron. In the study of cast iron it matters not what is the size of the bar if each iron is tested in exactly the same way. The ½in. square bar will show the characteristics of every iron more fully to an experienced man than a larger bar, as slow cooling will fail to mark so sharply the effect due to slight variations in any element. But there are other practical reasons in favour of the use of the ½in. bar. In order to give fair averages, and to avoid mistakes, six pairs of bars are needed, and three such sets of of six bars can be cast from one half pig. Any furnace owner will gladly furnish a sample half pig of 50lb. for a test, while such a quantity is readily handled, and the carriage is small. Even after all the required tests have been performed, part of the sample will remain, and can be stored for reference. The six broken bars, with the rest of the test, can be conveniently stored in a pigeon hole 2½in. square, and may be kept under lock; this gives twelve complete samples of the iron, each of which is light enough to send by post if desired. An examination of the specimens forwarded by Mr. Keep will show the value of these tests as applied to scientific research, especially when rare or expensive materials have to be used. Possibly some practical founders of the old school may be a little dismayed at the multiplicity of the apparatus and tests mentioned in this paper. To these we may say that the complete set of apparatus is intended to meet, as far as possible, the requirements not merely of the practical man, but also of the scientific investigator. For ordinary foundry use, to test the cupola product, the only apparatus required is that shown in Figs. 5 to 15 (with only Fig. 12 wedge) and the weight machine. If pig iron is to be tested, the furnace will be necessary; some founders will also need the impact machine. The hardness machine is too delicate for most foundry purposes; it can, however, be readily used by getting a number of standard pieces of different hardness, as registered on the machine, and then comparing the hardness of a particular sample, by means of the ordinary works tests, with the standard specimens.

The complete apparatus can at present be obtained at a price arranged so as to very little more than cover the actual cost of manufacture, from the Dunkirk Manufacturing Company, Dunkirk, N.Y. It is difficult to fix the price definitely at present; but there is every probability that it will not exceed £70 for the complete set, and would be less if a number were required. If these tests should be well received in this country, it is hoped that some firm here may be prevailed upon to take up the matter in the same spirit; but in such a case it is of great importance that perfect uniformity should exist in all sets of apparatus intended for a standard series of tests. The apparatus should of course be a correct copy of that made by Mr. Keep, who, in conjunction with Mr. Turner, would be happy to supply the necessary information. It may be once more mentioned that upwards of two years' use at the Michigan Stove Company's works, where about 70 tons of iron is daily cast into thin stove plate, has shown no cause for modification in the above tests. The quality of their castings has been kept regular, while mistakes have been avoided in the purchase of iron. With such information as this regarding any given iron, the founder should at once know whether or not it will suit his requirements. If any iron acts badly, a test will show what is wrong, and prove beyond dispute whether or not the iron is such as it was represented to be. Thus, the iron broker and the user are at once benefited. But, better than all, such knowledge removes superstition from the mind of the founder, and teaches him exactly what is the remedy for the defective iron, so that he can easily vary his mixture so as to use up brands of iron in connection with which he can now only complain to the furnace manager, or resolve never to touch it again.

The following is a short explanation of the accompanying figures:—

THE FURNACE.—Figs. 1 to 4 show the furnace. A is an arched flue to chimney, B the entrance for blast, C the plate to close ash pit, D a renewable seal for cover, E a removable plate to allow the last arch brick to be driven in to cover, F line of floor, which may be nearer the top if desired. Nothing but brick comes in contact with the fire. The grate bars are removable as usual. The inside lining can be removed and leave the outside shell. The door is lifted by the ring, and to this ring is attached a chain and counter weight.

PATTERNS AND MEASURES.—Figs. 5 to 15 show patterns and measures. W is an iron follow board, on which the patterns S and T and the chills G and G′ are perfectly bedded. Fig. 6 is a cross section. The moulder stamps the same number on each set of bars. D are guide pins to bring chills always to same position, D′ is a guide pin to prevent lateral motion of thin bar chill. The square bar chill is held by the follow board. E are four runners for the thin bar, and F two runners for the square bar. A notch is made in one end of each chill, and a corresponding one in the same ends of each bar T and S; Z is a draw pin for pattern, and Z′ a short steady pin to prevent lateral motion of pattern and fixed gate. K is the gate for the crook strip U, and N the gate for fluid strip H.

MEASURING.—Figs. 5 to 15. The same letters are used as in the last paragraph, everything being duplicated exactly except the same chills are used, and S and T are castings and the gates E F Z are not present. Four more steady pins O are used (but not used on the moulding follow board) to insure bar T being in the same position as the pattern. Between the ends of chills and bars P and L will be a space equal to the shrinkage of each bar. Through the iron follow board between each of these ends is a hole to admit the measuring wedge (Fig. 12), also shown in Fig. 6 at I I and J J, the companion dotted line showing the plain edge. V is a straight edge on the blocks, and Y′ is used for measuring crook strip U. The recess V′=$\frac{100}{1000}$in. is to allow the wedge shown in Fig. 12 to be used. It is run through as shown by I I (Fig. 6). If the "crook bar" is straight it reads $\frac{100}{1000}$ and is read O. If it is crooked the reading, less 100, is the record. M are springs on the blocks Y, which hold the ends of the crook strip against the straight edge V. This measure is of course not on the moulding follow board. The wedge shown in Fig. 11 is used for white irons. The bar S often blows at F. The clamps (Figs. 14 and 15) are put over the flaw.

TRANSVERSE MACHINE.—The knife edges and thin suspending steel ribbons are seen in Figs. 19 and 20. On a simple beam B, lightened by a portion being cut out of its long arm, runs a

Digitized by Google

KEEP'S TESTS FOR FOUNDRY IRON.

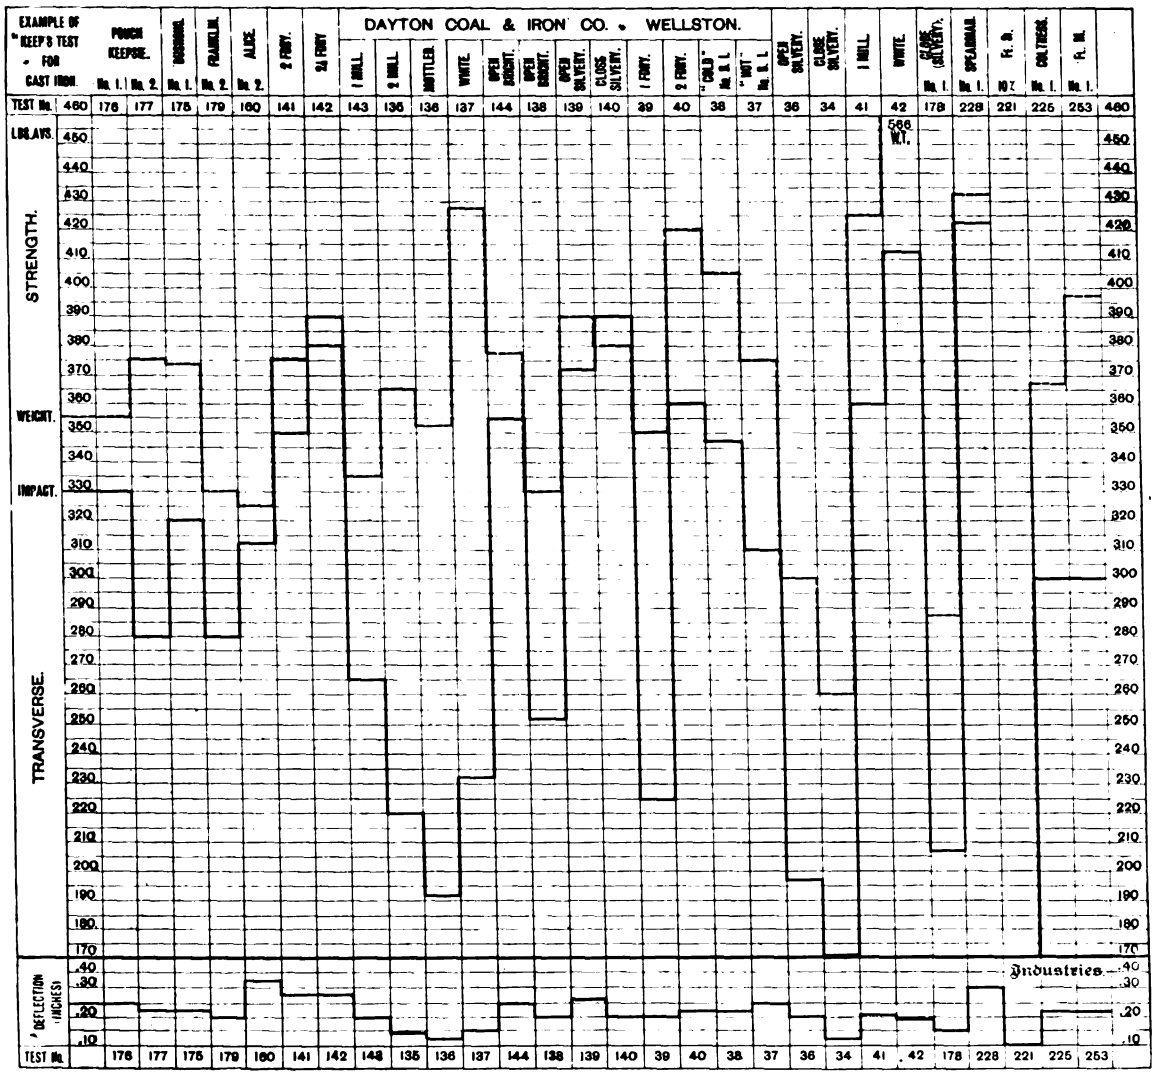

FIG. 38

rolling weight A propelled by the steel cord K K′ running around the wheels W and W′, which wheels are operated by a crank. The device at the forward end of beam is to catch the beam when it begins a sudden fall, but present no resistance to a slow fall. The illustration shows the recording device in position, and the steel cords G and G′ are to move the diagram holder F. The test bar C receives the weight through the strut D. Enlarged details of the recording device are given in Figs. 32 to 34.

IMPACT MACHINE.—Figs. 21 and 22 show the front elevation and plan of the impact machine. The 25lb. weight A swings on knife edges and the supporting steel ribbons S, and is caught by the catch T. By pressing a trigger the weight A is released, and strikes the hollow slide E, through which the blow is delivered to the test bar C. The recorder (Figs. 32 and 34) is shown on this machine, though in the plan (Fig. 22) it is cut off; but the extension is shown in Fig. 23. Fig. 24 and the upper part of Fig. 25 show the upper support to weight, and Figs. 30 and 31 the enlarged details. Fig. 25 is a plan of one of the webs of the truss. The trip to operate the recorder is shown in Figs. 26, 27, and 28. The device for catching the weight on the arc V is shown in Figs. 26, 27, and 29.

THE RECORDER.—This instrument is shown enlarged in Figs. 32 to 34. F is the paper holder with its continuous rolls of paper, which slides in the ways F′. The test bar T is clasped at its centre by a cage made from very thin sheet steel. N is the lever actuated by this cage, and the pencil at its end describes the diagram in the weight machine. The cage slides in the steel yoke M′. The arm P′ draws, by means of a pencil attached to its end, a diagram of the recoil of the bar, and P records the deflection of the bar in the same way. When struck in the impact machine P may be driven to P″. P″, P, and N all move in vertical lines, because of parallel motions. The cage and all levers are contained in a box and are not seen. The lever N has springs for bearings, and the rear bearing S can be varied by a set screw to bring the pencil point to any desired place on the diagram paper. A knife edge bearing for the test bar T is shown at E. An extension for the test bar is shown on each knife edge E. The diagram holder F is moved on the impact machine by a weight attached to the end of a cord running over a pulley, the length of motion being regulated by the trip; but on the weight machine it is moved by the steel cord G′.

TURNER'S HARDNESS TEST.—Figs. 35 and 36 show in plan and elevation the machine used for Turner's hardness tests. B is the pillar containing the bearing C of the head D. This is offset, and B is cut away to allow the weight K to hang on the first notch. L is the beam, and at its outer end, held by the screw Q, is the holder P, containing at its lower end a cutting diamond. The beam L moves freely up and down on the knife edge E, and is counter weighted by the weight F, which is moved by the screw G, and set by the screw H. To the head D is attached an arm, which runs past P and across in front, and then downward in front of P. To this end is attached a silk thread G, which is attached to the holder P. The operator takes hold of the handle V and pulls towards him, thereby actuating the arm which moves the head D. It also, by means of the thread, pulls the holder P without causing any friction on the knife edge E, and at the same time P is perfectly free to move up and down. With no weights on the beam, there is no pressure on the diamond. The carrier J weighs exactly 25grm. There are twenty-five divisions on the beam, and therefore the carrier on the first division brings 1grm. on the diamond. With three other 25grm. weights, each notch brings 4grm. on the diamond.

Notes.

A LARGE TORPEDO SHELL.

ACCORDING to the *Scientific American*, one of the new elements of construction rendered necessary by the invention of the dynamite gun, has been a brass shell for the projectile. Brown & Brothers, a firm in Waterbury, Connecticut, have succeeded in making a shell of seamless drawn brass, with conical head, $\frac{1}{16}$ths of an inch in thickness, and weighing 200lb. Its length is 6ft. 8in., and the inside diameter 14in., the whole being in one piece. It is produced by the cold flow of the metal, drawn into shape with the hydraulic ram. This shell is designed to carry 600lb. of explosive gelatine.

AMMONIA ENGINE.

THE use of ammonia for developing power is again brought into prominence by some tests lately made in New York. The engine used was a 60 h.p. Porter-Allen, and fitted with the Campbell ammonia apparatus. The amount of coal used per h.p. with the Campbell apparatus varied from 2·43 to 2·83; while the same engine had been running at an expense of 5·62lb. of coal, using water. The *Iron Age* gives a description of the apparatus as used in their printing establishment. A 200 h.p. Wright engine is used during the day and a 40 h.p. engine during the night, when there is a smaller demand for power. The plant presents no complications other than those attending an ordinary steam plant, and no special training of attendants is necessary. Any existing steam plant can be fitted with the apparatus with little trouble. The odour of ammonia about the plant is very slight. The liquid used has a specific gravity of 17°B6.

EXPERIMENTS WITH ANEMOMETERS.

AT the last monthly meeting of the Royal Meteorological Society, Messrs. G. M. Whipple, B.Sc., and W. H. Dines, B.A., reported on experiments made by the Wind Force Committee with anemometers at Hersham. A whirling apparatus with arms 29ft. radius was rotated by means of a small steam engine. On the arms of the whirler four different anemometers were placed. Each experiment lasted fifteen minutes, the steam pressure remaining constant during the run. For the Kew standard anemometer, with arms 2ft. long, the experiments gave a mean value for Robinson's factor of 2·15, and for two smaller instruments the factor was 2·51 and 2·96. Mr. Dines' helicoid anemometer gave very satisfactory results, the mean factor being 0·996.

THE LYONS SILK TRADE.

THE British Vice-Consul at Lyons says that the production of novelties was considerable throughout 1887, and that in tissues of pure silk the preference was greater for the coloured sorts than for black. Goods mixed with cotton wool or schappe dyed in the piece were in good demand. The figure given by the Lyons Conditioning House for 1887, is 3,784,284lb., which shows in comparison with 1886 a diminution of 332,599lb.; but this difference is attributed to the circumstance that in the last quarter of 1886, owing to an advancing market, many speculative transactions were made, which would otherwise have appeared in the trade of 1887. The official figure of silk exports of all kinds for the year 1887 is £8,606,040, or a decrease of £1,075,040 compared with 1886, which is partly due to the fall in prices.

PETROLEUM IN EGYPT.

IN our issue of the 21st January, 1887, we referred to the borings for petroleum which were being made at Jemseh. A Foreign Office report states that the Egyptian Government continued operations all last year; but although a depth of more than 2100ft. has been attained, they have met no favourable results, and in the meantime the boring there is suspended. Colonel Stewart, who represented the London Chamber of Commerce at the Petroleum Conference, held at Baku in 1886, is now exploring to the north and west of the Jebel Zeit range of mountains, and until his report is sent in, the Egyptian Government will probably not enter upon any new borings. Opinions differ very much as to whether the proper site has been chosen for the borings, and it is believed, should operations again commence, the borings would be from twenty to thirty miles inland.

THE SKILLED LABOUR MARKET.

THE Labour Correspondent of the Board of Trade reports that the revival in trade which commenced in the opening months of the year still continues to exercise a favourable influence on the condition of the skilled labour market, so far as can be gathered from the monthly reports of the trade unions which publish such returns. Sixteen unions have reported, with a total membership of 172,005, and though this figure forms but a small proportion of the aggregate workmen of the country, there can be no doubt that it reflects with tolerable accuracy the general aspect of the industries they represent. Of this number 8981 are unemployed, as against 10,668 last month. This is a net decrease of 1687, and the proportion per cent. of those out of work has fallen from 6·2 to 5·2. For the corresponding months of last year the proportions were 7·7 and 6·8. The rate of progress is therefore slow, and there seems reason to fear that the revival has well nigh spent its force. The greater portion of the improvement of the month is undoubtedly due to increased employment in the building and other outdoor industries, owing to finer weather, and in those trades the improvement since last month is indicated by a fall in the proportion of unemployed of from 8·5 to 5·2 per cent., the proportion at this time last year being 3·5 per cent. The iron shipbuilding and allied trades still show signs of improvement, although men do not go so briskly off the books as they did two or three months ago; and it is being remarked that new orders are not now booked with sufficient frequency to enable ship and engine builders to replace work now being executed with new commissions. The cotton and woollen trades do not show much activity, and most branches of the iron trade are in a stationary condition, as though an increased demand were needed to put them into more healthy action. Shipwrights (wood workers) have long suffered severely from trade depression, but now report that they are better employed than for some years past. The boot and shoe makers report improved trade.

Patent Record.

Compiled from "The Official Journal of the Patent Office," by W. E. Heys, *70, Market-street, Manchester.*

APPLICATIONS FOR PATENTS.

(The names in italics within parentheses are those of Communicators of Inventions.)

ENGINEERING.

11th May, 1888.

7042. Hurst, W. ..... Mules.
7043. Yates, J. ..... Machinery for preparing yarns or threads in the hank.
7045. Mauser, P. ..... Breech loading fire arms.
7050. Lake, H. H. ..... Universal shaft couplings (*Robes and Haskell*). (This Application was originally numbered in error 18037, A.D. 1887.)
7055. Worrall, J. ..... Machinery for producing a nap on velveteens.
7057. Worrall & Kershaw... Machinery for obtaining a cross-over finish and raising on cut pile fabrics.
7058. Holden & Ashworth... Doubling and twisting yarns.
7059. Taylor, G. ..... Apparatus for conveying coal by railway and for loading and discharging coal cargoes.
7061. McDougall, I. S., and others ..... Boilers or vessels lined with lead or other acid-resisting metal.
7063. Elliottt & Elliott ... Printing machines.
7065. Kennedy, E. S. T. ..... Radial tube steam boilers.
7066. Gibbons & Robinson... Gas engines.

12th May, 1888.

7069. Anderson, J. ..... Automatic brick moulding and pressing machine.
7073. Jackson & Martin ..... Auxiliary motor to be used in connection with steam engines and boilers for increasing their motive power without additional working expense.
7074. Houlden, H. W. ..... Transmission of power.
7075. Kelly, P. ..... Drawing off rollers for combing machines.
7076. Kelly, P. ..... Apparatus for actuating dabbing brushes for combing machines.
7077. Mills, J. ..... Steam boiler.
7078. Wilkinson, E. ..... Feeding wool to carding machines, and removing foreign matter from the fibre.
7082. Russell, B. ..... Glass houses.
7085. Hill, H. ..... Lace machines.
7094. Smith & Oldham..... Axle boxes for railway vehicles.
7099. Carter, W. ..... Hydraulic lifts.
7100. Lake, H. H. ..... Type writing machines (*Ganse*).
7103. McGlashan, D. ..... Sewing machines.
7104. Morton & Taylor ..... Fastenings for securing sheet metal to angle, tee, or other form of iron supports.
7108. Harkes, D. ..... Harrow.
7109. Parmiter, P. J. ..... Horse rakes.

14th May, 1888.

7115. Middleton, R. ..... Automatic locking safety appliance for entrances into hoists and lifts.
7117. Morgan, C. ..... Machinery for the manufacture of finings.
7118. Greaves, H. R. ..... Cotton gins (*Greaves*).
7121. Hogg, J. ..... Sight lubricator.
7125. Winby, W. E. ..... Hauling canal boats and sea-going vessels upon the endless cable system.
7128. Shakeshaft, J. ..... Signalling on railways.
7136. Blezard & Nelson..... Looms.
7140. Keavy, T. E. ..... Boot and shoe buffing machines.
7146. Oliva & Bardili..... Preventing the capsizing of ships without ballast or cargo.
7150. Vogel, Sir J. ..... Lubricators.
7151. Bucknill & Day ..... Gear for small steamers employed in laying and raising submarine mines.
7154. Mallett, J. R. M. ..... Apparatus for propelling boats by manual labour.
7160. Clark, A. M. ..... Rotary polishers (*The Zucker and Levett Chemical Company*).
7169. The United Sewing Machine Company and Sharpe..... Lock stitch sewing machine.
7170. Abel, C. D. ..... Furnace grates (*Langen*).

15th May, 1888.

7172. Renshaw, W. R. ..... Surface condensing apparatus.
7188. Baird, E. J. C. ..... Tram cars.
7189. Hindley, J. ..... Steam and gas generator.
7194. Craven, R. E. P. ..... Flues and fire boxes for steam boilers.
7197. Harrison, J. ..... Mitigating the vibration of spindles.
7200. Williams & Williams.. Axle box.
7201. Hart, F. B. ..... Operating railway signals.
7207. Brown, G. W. ..... Lubricators.
7210. Lake, H. H. ..... Diminishing the oscillation of railway vehicles (*Pullman*).
7213. Oliver, P. A. ..... Gunpowder mills.
7215. Burnham, W. ..... Moulding and welding metals.
7216. Reed, A. H. ..... Punch and die for sail grommets (*Wilcox*).
7217. Reed, A. H. ..... Sail grommets and washers used for the same (*Wilcox*).
7218. Benson, W. A. S. ..... Cutting screws in a turning lathe by hand.
7220. Henderson A. C. ..... Manufacture of wire healds (*Bénazet*).
7222. Skinner, A. L. ..... Power looms.
7224. Patrick, J. J. R. ..... Apparatus for regulating teeth.
7226. Steel, W. H. ..... Sewing machines.
7227. Boulton, M. P. W. ..... Steam engines.
7229. Schubert, V. F. ..... Stone breaking machine.
7234. Las, R. le ..... Washing and sorting coal.

16th May, 1888.

7247. Glover, L. ..... Mules.
7248. McGregor, A. ..... Reaping and mowing machines.
7249. McGregor, A. ..... Machinery for pulping turnips.
7255. Fleming & Ferguson... Bucket ladders of dredgers.
7265. Vaughan-Arbuckle, B. Protecting ordnance by the application of armour plates.
7266. Vaughan-Arbuckle, B. Directing the fire of guns.
7269. Thompson, W. P. ..... Type writers (*The Standard Type Writer Manufacturing Co.*).
7273. Schweitzer, T. O. ..... Sizing machines.
7274. Anson, W. ..... Breech loading small arms.
7276. Brigg, T. H. ..... Wheeled vehicles.
7277. Larsen, H. S. ..... Automatic cork cutting machines
7282. Bennett, M. ..... Hand guard for rifle barrels.
7287. Davis & Turner ..... Gas heated boilers.
7290. Morton & Taylor ..... Railways.
7292. Laillet, C. A. H. ..... Automatically re-utilising waste steam.

17th May, 1888.

7294. Wilhelm, J. ..... Joining sheet metal tubes.
7298. Taylor, T., & others ... Gig mills.
7299. King, J. T. ..... Rolling metal rods (*Day*).
7304. Gimson, J., & others ... Heel burnishing machines.
7305. Fawcett & Fawcett ... Double pressing motion for moulding and pressing bricks and other articles.
7312. Burgoine, A. ..... Sailing craft.
7313. Whitehead & Haworth Safety clutch for barring engines.
7316. Greener, W. O. ..... Rocket guns.
7319. Worsley, J. E. ..... Apparatus for breaking up cop waste for re-spinning.
7325. Filbee, G. H. ..... Tubular boiler.
7326. Dixon & Clayton ..... Pickers of looms.
7329. Teague & Wellington Stamping machinery for crushing ores.
7336. Smith & Paget ..... Roller bearings for washing machines.
7339. Bamforth, S. ..... Fire bars for furnaces.
7341. Twelvetrees, W. N. ... Washing machines.
7345. Rongier, H. ..... Manufacture of weldless chains.
7354. Twibill, J. ..... Steam generators and fuel economisers.

ELECTRICITY.

11th May, 1888.

7035. Langdon, W. E. ..... Electrical coupling.

14th May, 1888.

7111. Davies, J. H. ..... Electrical couplings.
7131. Thomson, Sir W. ..... Measuring and regulating electric potentials and currents.

16th May, 1888.

7256. Rowling, F. ..... Holder, switch, and cut-out for electric glow lamps.

17th May, 1888.

7301. Thomson, Sir W. ..... Measuring and regulating electric potentials and currents.
7321. Kent & Beaumont ..... Storage batteries.
7332. Edmunds, H. ..... Conductors of electricity.
7333. McKenzie, R. ..... Electrolytes for batteries (*Weymersch*).

CHEMISTRY.

11th May, 1888.

7046. Borsche & Brünjes..... Conversion of chloride of calcium into chloride of magnesium and carbonate of lime.
7047. Caspers, C. J. ..... Machinery for impregnating liquids with carbonic acid.

12th May, 1888.

7095. Thompson, W. P. ..... Detergent compounds (*Parsons*).

14th May, 1888.

7123. White, W. ..... Sodium and potassium.
7159. Dahl, S. T ..... Amalgamating gold.

15th May, 1888.

7177. Thompson, W. P. ..... Disinfecting compounds (*Belcher*)
7187. Hannay, J. B. ..... Treating ores.

16th May, 1888.

7257. Fenton & Partridge... Preventing loss in the smelting of ores (*Woolford*).
7279. Soldenhoff, R. de..... Washing ores.
7285. Mallet & Pagniez ..... Distilling ammoniacal liquids.

17th May, 1888.

7331. Mills, B. J. B. ..... Manufacture of metallic twist or bullion (*Mallet-Guy*).
7334. Lennard, F. ..... Distillation of tar.

MISCELLANEOUS.

11th May, 1888.

7019. Heaton, R. ..... The regulation of the motion of Nottingham and trolling reels.
7020. Alber, W. ..... Improved oil cement.
7021. Whitehead & Shaw..... Nut locks.
7024. Hargraves, E. H. ..... Finishing cotton goods.
7025. King, R. ..... A tumbler for gaff jaws.
7027. Wolloms, J. W. ..... Safety window fastenings.
7028. Bingham & Bingham.... Horseshoes.
7029. Campbell, M. E. ..... Metallic folding crates.
7031. Wright, G. ..... Register stove grates.
7032. Mackenzie & Wake..... Securing railway keys in railway chairs.
7033. Hannay, J. B. ..... Anti-fouling coatings for ships' bottoms.
7034. Wishart, J. ..... Indicating the length cut from a piece of textile fabric.
7036. Kenyon, J. H. ..... Improvements in weaving by moistening the atmosphere with water, antiseptic, or other liquids.
7040. Walker & Sisterson... Reducing the pressure of gas.
7041. Moyse, E. B. ..... Stoppering glass bottles.
7054. Imray, O. ..... Tongs for handling clothes and fabrics during washing (*Hardy*).
7056. Hollins, M. D. ..... Tiles.
7060. McDougall, I. S., and others ..... Apparatus for making bisulphites used in the treatment of wood pulp.
7062. Poujade, J. B. H. R. ... Connecting pipes.

12th May, 1888.

7071. Bödtker, A. ..... Slag manure.
7072. Nobiling, M. ..... Tricycles.
7080. Schulte, J. ..... Manufacture of non-conducting lagging.
7086. Creed, W. G. ..... Ventilator.
7087. Hughes, J. H., & others Fire proof material.
7089. Richardson, J. ..... Bottle opener.
7091. Thomas, W. B. ..... Lamps.
7096. Thompson, W. P. ..... Locks (*Polleri*).
7097. Meeze, A. G. ..... Manufacturing gas.
7098. Whitehouse, J. ..... Traps for sewers.
7101. L'Ancienne Société J. G. Bideau et Cie., and Michelin ..... Brake blocks.
7105. Cooper, W. C. ..... Compasses.
7106. Freeman & Jenkins ... Coating of metal plates with tin.
7107. Hunt, T. ..... Gauges for steam boilers.
7110. Barton, W. ..... Improved instrument for indicating angles and courses and for measuring distances.

14th May, 1888.

7113. Thorburn, Bain, & Co. Printing by letterpress in gold or colour on glass, china, porcelain.
7120. Sumners, H. ..... Fire proof curtain.
7124. Hall, B. G. ..... Clinometer for measuring vertical angles.
7126. Walsh, B. ..... Carts used for spreading liquid manure.
7132. Lock, G. H. ..... Ventilating drains.
7134. Potter, E. ..... Discharging slag balls from bogies.
7142. Penhorwood, C. F..... Cleaning wall papers.
7149. Smith, G. H. ..... Producing manifold copies.
7152. Borsche & Brünjes ... Manufacture of hollow bodies of cement.
7153. Coop, W. ..... Manufacturing lead shot.
7155. Craig, S. ..... Treating flax.
7156. Bruzon, R. ..... Droppers for wire fencing.
7157. Varley, J. J. ..... Screw stoppers.
7163. Héley, A. ..... Manufacture of boots.
7167. Sargent, T. R. ..... Tilting casks.
7168. Abel, C. D. ..... Roasting, calcining, and drying materials (*Langen*).

15th May, 1888.

7174. Walker, F. ..... Packing for pistons (*Jaeger*).
7178. Burgess, H., & others... Bobbins for looms.
7181. Bolland, T. ..... Distilling apparatus for spirits.
7182. Goodchild, W. ..... Bolts.
7183. Turner, W. H. ..... Towing or scouring ceramic productions in the clay or biscuit state of manufacture.
7184. Marriott, A., & others Cutting a spiral groove in a weft bobbin.
7191. Moseley, J. ..... India-rubber compounds for dental purposes.
7198. Osborne & Richardson Cutting sheet glass.
7203. Johnson, S. A. ..... Automatic extinguishers for lamps.
7204. Berliner, E. ..... Improved process of recording sounds for reproduction.
7206. Straub, C. ..... Wall covering composition.
7211. Hawkins, I. T. ..... Sewers.
7219. Williams, H. ..... Artificial fuel.
7221. Lewis & Hunter..... Tipping coal in collieries.
7223. Smith G. ..... Sockets for earthenware pipes.
7228. Sandison, W. M. ..... Concentrating cane juice.
7230. Edwards, E. ..... Shafts of carriages (*Labarre*).
7231. Kustel, O. ..... Ships' logs.
7232. Earnest, J. T. & others Heating and ventilating railway carriages.

16th May, 1888.

7237. Patterson, W. ..... Safety lamps.
7239. Baller, E. R. ..... Automatic locking bolt.
7240. Main, R. R. ..... Base plates for fencing standards.
7245. Price, T. ..... Manufacture of tin plates.
7246. Appleyard, G. ..... Pulverising and sifting salt.
7252. Pirrie, N. ..... Automatic station indicators.
7259. Death, J. ..... Distilling spirits and distillery plant.
7262. Sheldon, J. ..... Velocipedes.
7264. Layland, A. ..... Manufacture of pens.
7268. Foster, F. ..... Stoppering bottles.
7270. Jackson & Ferguson... Lids for drum heads and for holes in sheet metal structures.

Digitized by Google

7271. Crowley, J. ..... Lamps.
7272. Lumley, M. ..... Machine for making wire loops for wiring the corks of bottles.
7283. Willis, E. J. ..... Safety cycles.
7284. Forestier, M. ..... Valves.
7288. Phillips, J. ..... Gullies and drains.

17th May, 1888.

7296. Bentley, J. ..... Screw stocks.
7302. Bodtker, A. ..... Slag manure.
7306. Wilmot, C. F. ..... Steering velocipedes.
7307. Fawcett, A. ..... Clarification of sewage.
7309. Richardson, J. T. H. ... Manufacture of glass.
7314. Whyte & Allan ..... Metallic packing for piston rods.
7317. Jackson, R. ..... Metallic drums and lids.
7322. Marsh, R. C. ..... Watches.
7323. Grayson, J. ..... Preventing the accumulation of fluff in winding frames.
7335. Fullford & Van Laun Gas lamps.
7337. Brock, A. ..... Lamps.
7347. Wilson, R. H. ..... Pruning shears.
7350. Brasier, E. ..... Processes for treating "Bauhinia Vahlii" and other fibrous materials.
7351. Spencer, A. G. ..... Preventing rattling of railway carriage windows.
7353. Gibbons, J. V. ..... Hay rakes and tedders.
7355. Treunfeld, R. von F. . Field telegraph conductors.
7356. Harrison, G. A. ..... Manufacture of linoleum.
7358. Parker, A. J. ..... Manufacture of compounds and their utilisation as printing surfaces.

COMPLETE SPECIFICATIONS ACCEPTED.

Persons interested in opposing the grant of the following patents may give notice of opposition at any time within two months after the dates given.

ENGINEERING

19th May, 1888.

6935. Starley, J. K. ..... Manufacturing articles from rod wire or tube.
7230. Barwick, J. E. ..... Heating steam generators by kilns.
7326. Hadden, H. ..... Traverse warp machines.
7402. Smith & Cowan ..... Steam generators.
7921. Harrison, J. ..... Knife cleaning machines.
7922. Johnson, J. Y. ..... Mules (*La Société A. Grandjeans et Cie*).
8448. Lake, H. H. ..... Sewing machines (*Wheeler*).
8454. O'Donnell, J. P. ..... Hydraulic machines for stamping rivet and bolt heads (*Fréhault*).
8562. Lake, H. H. ..... Warping machines (*Wiedersheim*)
8687. Colam, W. N. ..... Cable tramways.
8954. Johnson, J. Y. ..... Driving spindles in spinning machines (*Masson-Pinel*).
9236. Griffiths & Anthony.. Slide valve.
9343-4. Barrow, J. ..... Lathes.
9380. Cleathero & Stewart. Safety apparatus for lift and mine cages.
9432. McQueen & Moores .... Nipper mechanism of combing machines.
9437. Kenworthy, E. N. ..... Roller bearing for mangling machines.
9501. Thompson, W. P. ..... Furnaces for burning hydrocarbon fuels (*The Aerated Fuel Co.*).
9816. Bertrand-Bocandé, O.. Switch and turntable for railways.
9849. Ehrlich, D. ..... Washing machines.
9860. Preston, E. J. ..... Pumps.
9942. Wailes, E. F. ..... Stern posts and rudders of ships.
9945. Hopkins, M. ..... Washing apparatus.
9992. Thompson, W. P. ..... Grain binders (*McCormick*).
10010. Howard & Gibbs ..... Harvesting machines.
10045. Attenborough & Kent Filling up apparatus as applied to knitting machines known as "Cotton's Patent."
10088. Mason, J. ..... Loose reed looms.
10101. Sauce, E. de la, & others Metal plates and machine for bending the same.
10148. Burgess, G., & others... Regulator applicable to sectional warping & beaming machines.
10365. Perkins & Perkins..... Machinery for rolling roads.
10504. Buck, T. ..... Operating railway waggons upon inclines.
10840. Berry, H. ..... Hydraulic punching machine.
10901. Hardley, S. ..... Steam washing machine.
11444 Abel, C. D. ..... Igniting apparatus for gas engines (*The Gas Motoren Fabrik Deutz*).
11894. Healey, B. D. ..... Furnace rocking bars.
12061. Bayliss, T. R. ..... Machinery for stamping and cutting metals.
12893. Harrison & Sheard.... Testing gas pipes and fittings.
16443. Shepherd, J. ..... Steps for shaft and axle bearings and for bushing loose running pulleys and wheels.
17652. Garratt & Scott ..... Preparing flax for spinning.
17766. Ribault, G. E. ..... Coupling rolling stock.
68. Rowbotham, T. ..... Corve wheels and axles.
1607. Westley, J. ..... Picker for looms.
1998. Leiga, H. H. ..... Screw propellers (*Le Solliec*).
2444. Rariden & Heath ..... Car couplings.
3313. Bollmann, L. ..... Sewing machines.
4978. Lake, H. H. ..... Machines for pulverising ores (*Gates*).
5336. Preble, J. Q. ..... Weighing machines.
5437. Schaeffer & Oehlmann Lubricators.
5471. Colley, A. ..... Magazine for rifles.
5585. Bonvillain & Guyon... Hydraulic apparatus for compressing and baling cotton.
5622. Richards, F. H. ..... Button setting machines.
5636. Dynes, W. ..... Clover seed shelling machine.
5641. Mauser, P. ..... Breech loading fire arms.
5644. Allison, H. J. ..... Casting ordnance (*Gatling*).
5712. Ellis & Sturla ..... Numbering machines.
5741. Lake, H. H. ..... Manufacture of lattice work (*Golding*).

ELECTRICITY.

19th May, 1888.

6809. Eshelby & Eshelby .... Electric bell indicators.
6918. Gedge, W. E. ..... Telegraphy (*Claude*).
7042. Chapman, F. G., & others Electric arc lamps.
9829. Stanley, T. ..... Dynamo-electric machines.
9904. Grabau, L. ..... Insulating coatings in electrolytic apparatus.
10195. Hall, J. P. ..... Dynamo-electric machines.
10575. Emmott & Ryder ..... Instruments for electric measurement.

CHEMISTRY.

19th May, 1888.

9315. Imray, J. ..... Azoic colouring matters (*La Société Anonyme des Matières Colorantes et Produits Chimiques de St. Denis, Poirrier, & Rosenstiehl*).

MISCELLANEOUS.

19th May, 1888.

6817. Burke & Leather ..... Centrifugal percussion fuse for igniting the bursting charges of shells.
7298. Leonardt, F. C. ..... Manufacture of paper boxes.
7567. Owen, D. ..... Manufacture of tin plates.
8345. Ruscoe, J. ..... Taps, dies, reamers, and cutters.
8491. Smith, T. ..... Needle for sewing machines.
8802. Schmitt, K. ..... Velocipedes.
9108. Dodge, J. M. ..... Chain cable.
9630. Clegg, W. ..... Velocipedes.
9762. Dinsmore, J. H. R. ..... Heating, drying, and circulating air.
9771. Rylands, D. ..... Valves for internally stoppered bottles.
9886. McIlvride, A. B. ..... Collapsible boxes.
9887. Rust, J. ..... Improved material for colouring paints and cements.
9901. Abel, C. D. ..... Illuminating railway carriages (*Rotten*).
9912. Marriott & Cooper ... Driving gear for bicycles.
9931. Singleton, T. ..... Size boiling, beaming and pressing yarn in tape frames.
9949. Sengel & Dobler ..... Gelatinised cloth or artificial parchment.
9973. Gratrix, S. ..... Speaking tubes.
9993. Downie, T. ..... Metallic packings for piston rods.
10025. Burton, W. C. ..... Spindles.
10037. Markham & Shann..... Bicycles.
10061. Warner & Goslin..... Heating apparatus for water and air.
10073. Hannay, J. B. ..... Fire extinguishing apparatus.
10113. Gilliard, A., & others.. Production upon fibres and fabrics of colours varying from black or brown black to blue black and blue.
10227. Cock, W. J. ..... Removing débris from tram rails.
10355. Hill, J. ..... Tilting casks.
10531. Baller, E. ..... Lamp trimmer.
10650. Cohnreich, P. ..... Oiling or fatting wool.
10669. Wolff, C. ..... Machines for stripping the quills of birds.
10989. Barrett & Varley ... Screw stoppers for bottles.
11810. Day, C. A. ..... Locks (*Cole*).
14248. Hudson, F. ..... Rollers for castors.
14422. Newman, G. F. ..... Door springs.
14432. Walker, J. ..... Gas lamps.
15251. Sperry, C. ..... Indicating the speed of and distance run by a vessel.
15254. Clarke, S. ..... Lamps.
15811. Watson, G. ..... Hydraulic gas valve.
15861. Braime, T. F. ..... Oil cans.
16856. Caldwell & Turner ... Fasteners for belts and driving bands.
17694. Dehany, G. E. ..... Extinguisher for lamps.
2206. Aynsley, J., & others.... Ovens for baking or firing pottery ware.
2422. Hargrave, F. ..... Rocket signalling at sea.
2607. Dobbs, C. J. ..... Annealing kilns for slag blocks.
4641. Greene, P. R., & others. Cores for tubes.
5030. Newton, P. A. ..... Cock for conduit pipes (*Christophersen*).
5063. Kilsby, W. ..... Lamps.
5068. Tautz, F. G., & others... Manufacturer of hats, caps, and gloves.
5106. Disturnal, T. J. ..... Apparatus for heating & drying.
5323. Erckel & Englehardt. Sharpening scythes.
5439. Ashberry, P. ..... Sheep shears.
5440. Bennett, J. F., & others. Compasses.
5472. Colley, A. ..... Cleaning the chamber of Martini-Henry rifles.
5635. Bariquand, L. F. J., and others ..... Clipping or shearing instruments
5689. Swallow & Proctor ... Artificial fuel.
5703. Newton, P. A. ..... Watches (*The Ansonia Clock Co.*).
5735. Lake, H. H. ..... Separating grease from steam (*Lowdon*).
5736. Hogg & Hogg ..... Spindles.
6285. Born, P. ..... Apparatus for producing jets of spray (*Schmid*).

PATENTS VOID THROUGH NON-PAYMENT OF RENEWAL FEES.

(To the 12th February, 1888, inclusive.)

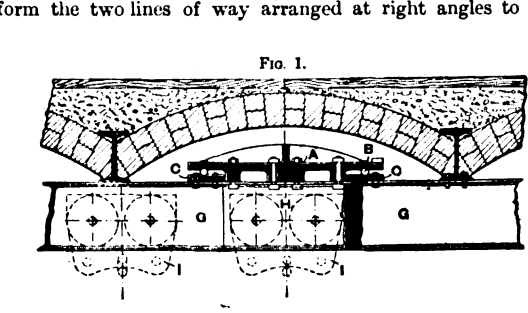
ABSTRACTS OF BRITISH PATENT SPECIFICATIONS.

Compiled from the Published Specifications by W. E. Heys, 70, *Market-street, Manchester.*

ENGINEERING.

Turntables for Overhead Rails.—*A. Goodwin & A. Goodwin jun., London.*—Fig. 1 shows a vertical section and elevation, and Fig. 2 a section through two different planes. A is a table or plate arranged to revolve on anti-friction balls B, which are supported on an annular plate C. This plate is fixed to the four adjacent ends of the two pairs of girders G and G¹, which form the two lines of way arranged at right angles to each

Fig. 1.



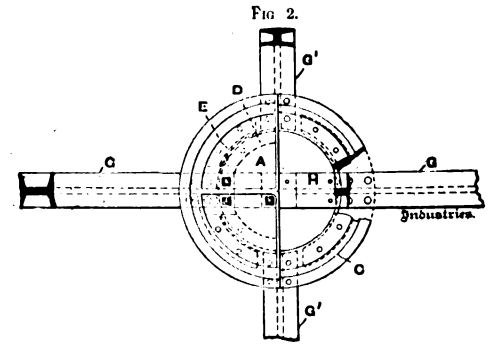


Fig 2.

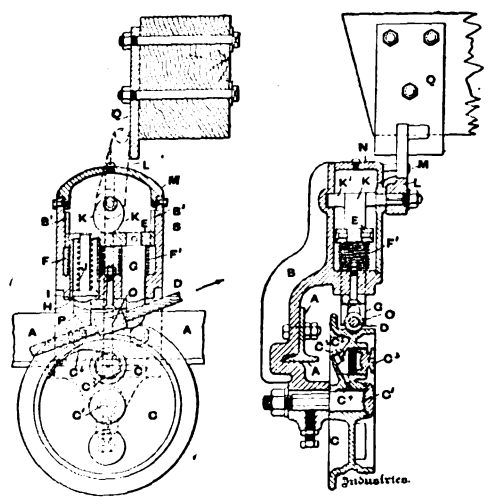
other. The length of way H is secured to the under side of the table A, in combination with which it constitutes a turntable. It is of such a length as to fill the space between the adjacent ends of each pair of girders. The plates D project downwards, and are arranged so as to block that line of way for which the turntable is not set. The plates E are fixed to the under side of the annular plate C, and project downwards so as to serve as guards to prevent the vehicle leaving the length of way H during the rotation of the turntable. A catch lever is pivoted to one of the girders; one of its arms is weighted, and is adapted to fit into one or other of four slots formed in the table A, and a chain is secured to the other end of the lever to enable it to be raised out of the slots. By this arrangement the turntable may be locked while the vehicle is being run on to it. Four claims are made.—No. 9962. July 16th, 1887. 8*d*.



Utilising Scrap Iron.—*J. Gilligan, Abertillery, Monmouthshire.*—This invention relates to the working up of scrap iron and steel in a puddling furnace, by balling it up in the molten metal in the furnace before the stage of full boil has been reached. In carrying out this method, the scrap is introduced in bundles into the furnace, and is moved about the bed until a sufficient amount of puddled iron has adhered to it; the balls are then ready for the hammer. As scrap iron or steel readily unites in any proportion with puddled iron, any quality of

Digitized by Google

metal may be used in this process, according to the quality required for the finished material. The scraps are thrown in and balled, without any loss in yield to the metal in the furnace, owing to the metal in the puddling furnace being coated with slag. The inventor claims the method of working up scrap iron and steel by balling it up in molten metal in a puddling furnace before the metal is on the boil.—No. 11868. September 1st, 1887. 4*d*.

CLUTCH.—*W. Sisson, Falmouth.*—The object of this invention is to enable the interlocking clutches to be engaged and disengaged freely without the usual shock and consequent wear and tear of the parts, which is caused by their sudden engagement at a high speed. The clutch handle, in addition to actuating the clutch, is also made to control the motive power of the machine, so that before the clutches can be either engaged or disengaged the motion of the machine is arrested to a greater or less extent. Immediately after engagement the handle is moved back into its original position, and the former conditions of the machine are re-established. The manner in which this reduction of the speed of the engine is accomplished may be varied; but the inventor prefers to use a mechanism by which the steam supply is shut off or reduced when the handle is turned, so that the speed of revolution becomes sufficiently slow for the purpose before the handle can be further turned in order to bring the clutch mechanism into operation. The inventor claims the arrangement of mechanism whereby high speed clutches can be disengaged and engaged while the machine is running slowly, and the arrangement by means of which the same handle serves to perform the series of operations required. —No. 7296. May 19th, 1887. 8*d*.

TELPHERAGE.—*H. H. Lake, London.* (*T. Otto, Schkenditz, Germany.*)—Improvements are here introduced into the method of coupling the trucks to the hauling ropes of wire ways or elevated railways. The claw grip illustrated in the accompanying figure may be advantageously used on steep gradients. A is the cross bar of the suspension frame for the buckets, and B is a casting which is firmly attached to the cross bar; the roller C is supported on a spindle C^1 and acts as a guide for the hauling rope D when the bucket is uncoupled from the rope. For the purposes of lubricating the spindle, a recess C^2 is formed in the wheel; the oil is held in its place by the screwed plug C^3, which is prevented from shaking loose by means of the ratchet teeth C^7 and the spring C^6. The cross head E is supported by the springs F F^1, and may be moved vertically in the guides B^1; to

the lower side of the cross head is attached a forked gripper G and a sleeve H; the sleeve also carries another gripper I, which is constantly pressed against an inwardly projecting flange on the lower end of the sleeve by means of a spring J. An eccentric K is attached to a spindle K^1, and has a projecting extremity upon which is fixed an arm L. In coupling a truck to the rope, the latter is first placed upon the roller C, and then the cross head E is lowered by turning the lever L; the grippers G and I are thus caused to engage with the rope. The travel of the lever is limited by the stop M. When one of the carrier collars O, which are placed at various points along the rope, approaches the gripping apparatus, while the rope is in motion, the collar presses against the inclined surface P of the gripper I, thus lifting the gripper and striking against the other gripper G. As soon as the collar has passed the first gripper I, the latter is forced down by the spring J and the coupling operation is complete. In order to stop the buckets at any point of the line, it is necessary to release the grippers G and I; the lever L strikes against the fixed plate Q, which is placed in the position where it is desired that the buckets shall be released, and is forced back; the eccentric K is turned, whereupon the springs F F^1 raise the cross head E and with it the grippers G and I to a sufficient height to allow the hauling rope and the carrier collar to pass freely between the grippers and the roller C. Seven claims are made for the coupling device, for the construction of the collar, and for an arrangement of the truck frame.—No. 7507. May 23rd, 1887. 11*d*.

EDGE PLANING MACHINES.—*J. Barrow, Johnstone, Renfrew.*—In edge planing machines it is found that the strain on the tool, when cutting the plate, causes the saddle to twist sideways on the bed and the tool to dig into the work. In order to eliminate this disadvantage, the inventor so arranges the sides of the bed that the pressure of the cut upon the saddle tends to release the tool instead of causing it to dig into the work. The bed is provided with slides, which are arranged inside instead of outside, and into which the saddle is fitted, so that when the saddle twists sideways the tool is released. The slides are nearly square to the face of the bed, and any lifting action that the tool may give to the saddle is prevented by a square slide on the outside of the bed; the saddle is clear of this slide at the edge, and is fitted only at the under part of the projection of the same slide. There are two claims.—No. 651. January 16th, 1887. 11*d*.

GRAIN GRINDING MILLS.—*H. H. Lake, London.* (*H. H. Coles, Philadelphia.*)—Fig. 1 represents a central vertical section of a grinding mill embodying this invention, and Figs. 2, 3, 4 show detailed views of parts. A represents the frame, and B the driving shaft. The runner D is secured to the shaft B, and the bed E is secured to the frame A. The casing F contains the runner and bed, and is extended laterally for the purpose of supporting the hopper H. The shaft B has a sliding motion on its bearings; between it and the bearing C is a coiled spring K, whose effect is to force the runner from the bed. In order to force the runner towards the bed, a ring L is employed, whose interior is threaded and engages with a threaded sleeve M encircling the shaft B. The ring is placed between the bearings C and an arm N, whose lower portion is in the form of a boss N^1, and whose upper part is attached to the outer wall of the

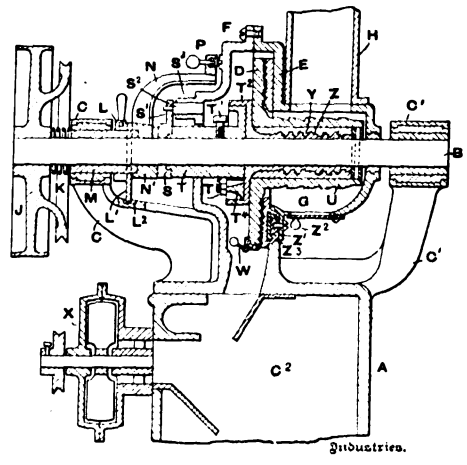


FIG. 1.

casing F by means of a spring pressed pin P. The side of the boss N^1 opposite to the ring L has a cam projection Q, which is in contact with the cam R of a sleeve S. Contiguous to the sleeve S is a sleeve T, which is secured to the shaft B by a bolt T^1. The sleeve S is prevented from rotating by means of the arm S^1 projecting from the sleeve, and is freely connected with a pin S^2, which slides in a bearing S^3 on the wall of the casing F. When L is turned on the sleeve M so as to be moved towards the lever N, it is pressed against the lever, the boss N^1, the sleeve S, and the sleeve T, whereby the shaft B is moved away from the pulley, thus causing the runner to move towards the bed. By these arrangements the mill may be adjusted for fine or coarse grinding. If any obstruction enters between the

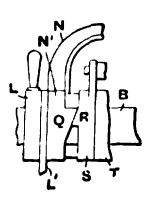

FIG. 2.

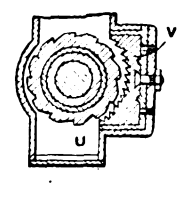

FIG. 3.

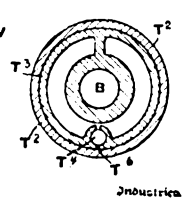

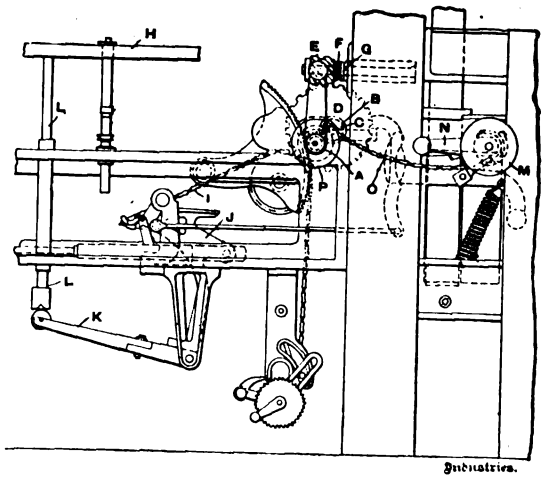

FIG. 4.

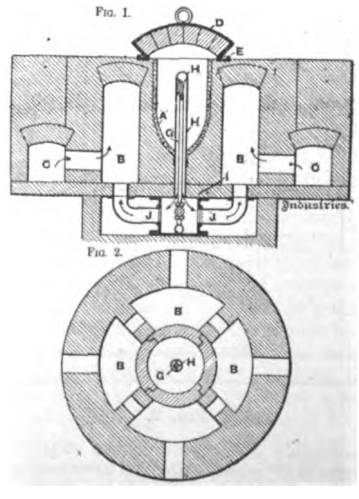
runner and the bed, its removal is accomplished by releasing the pin P and rotating the lever N; the wide part of the cam of the boss N^1 thus leaves the similar cam on S, and the spring K exerts its pressure on the shaft B, and quickly removes the runner from the bed to allow the obstruction to escape. The runner has a tubular toothed extension U, which fits with a toothed concave V. In the part G of the apparatus, the grain is primarily broken before it is treated by the runner and bed. The runner is secured to the shaft by means of the rim T^2 connected with the runner, and encloses a split collar T^3, which is formed with the sleeve T. At the ends of the collar T^3 is a conical plug T^4, which has its outer end threaded for engagement with the nut T^5. The degree of expansive action of the plug may thus be regulated. A pin T^6 prevents the rotation of the plug. When the plug T^4 is properly tightened against the ends of the collar T^3, the rim T^2 and the collar are firmly connected, and the power of the shaft is imparted to the rim and runner. A filling of soft metal Z is interposed between the sleeve Y and the runner. The bed is secured to the frame by the dovetailed lugs Z^1. Eighteen claims are made for these various improvements in the adjustments of the various parts.—No. 17798. December 27th, 1887. 8*d*.



NEWSPAPER PRINTING MACHINERY.—*J. H. Sedgwick, Wolverhampton.*—The object of this invention is to enable late news, such as the result of a race, to be introduced into the stereo forme of a newspaper printing machine at the very last moment before going to press. A box is adapted to fit and to be retained in an aperture provided for its reception in the forme. The frame of the box is bevelled externally to fit the undercut sides of the aperture in the stereo, and is curved to conform with the curvature of the cylinder. The grooved type holders are bevelled at one end and rebated at the other, and they take under the corresponding ends of the box. To enable them to be inserted after the stereo has been fixed on the cylinder, a small gate is provided at one end of the box, and is closed by a spring latch. At the end of the box is a vertical slot, which contains a similar holder for the figures to be inserted opposite to the names of the horses; this type holder is bevelled or rebated at one end to engage with the end of its slot, and is locked in place at the other end by a lever latch, which is itself kept securely locked by the end of one of the adjacent horizontal type holders taking under the tail end of the lever. Three claims are made.—No. 2862. February 25th, 1888. 8*d*.

RING SPINNING AND DOUBLING FRAMES.—*J. Edge, Wigan, and E. Tweedale, Accrington.*—The mechanism here described is designed to insure the automatic lowering of the ring rail just before the "knocking off" takes place. A carrier wheel gears with the teeth on the quadrant lever, and with a pinion on

the end of a cross shaft. On the other end of the cross shaft is a worm wheel engaging with a worm, whose boss forms one half of a clutch box; the worm is loose on the stud, and the other half of the clutch box is formed by the end of the collar of the roller gear. The teeth of the quadrant gear with the pinion A, which gears with the pinion B on the cross shaft C. The worm wheel D is also on the shaft C, and the worm E is loose on the shaft of the ordinary carrier connected with the gear for driving the front roller. The inner boss of the worm E forms one half of the clutch F, whose corresponding half G is fast on the shaft of the carrier. Directly the quadrant is released its teeth turn the wheels A B D, and consequently one or more teeth of the wheel D press against the sides of the threads of the worm E, and slide the worm on its shaft and so engage the two parts of the clutch; as the part G is fast to its axis, the further descent of the quadrant is arrested. The ring rail H and the connections I J K L are regulated and controlled by the motion of the wheel on the axis of the carrier connected with the gear for driving the front roller; and as the latter gear is gradually brought to a state of rest by the knocking off motion and by the transfer of the driving strap from the fast to the loose pulley, it follows that the quadrant and its connections and the ring rail will be automatically and quietly eased down. The pulley M on the axle of the setting lever N is connected by a chain O with a similar pulley P on the axle of the wheel A, and insures the simultaneous movement of the strap fork and the segment lever. The inventors claim the parts A B C D E F G put in operation through the quadrant, and controlled by the wheel on the shaft of the ordinary carrier connected with the gear for driving the front roller.—No. 7233. May 18th, 1887. 8*d*.

CASTING METALS.—*B. H. Thwaite, Liverpool.*—The essential feature of this invention is the cooling of the metal from the centre to the outside. The object of this reversal of the usual order is to allow the enclosed gases to escape from the inside of the metal. Previously to pouring the metal into the mould, a cooling tube is placed exactly in its centre, and in such a position that the absorption of heat from the mass is uniform. The cooling tube is placed inside another of slightly greater diameter, the latter tube serving for the escape of the cooling fluid. The application of this method to the casting of projectiles is illustrated in the accompanying figures. The mould A is surrounded

by a gas combustion flue B, which is supplied with fuel from the flue C, and over the mould is placed a cover D which rests on a recess E. The inner pipe G supplies the cooling medium, which consists of either refrigerated air, oil, steam, or water; and the annular space between the pipes G and H allows the return of the fluid. If air is the refrigerating medium, it is afterwards utilised to support the combustion of the gaseous fuel, and for that purpose it is led through the connecting flues J into the flue B. The cooling pipe H is made of the same quality of steel

Digitized by Google

as is used for the projectile, and is fixed in a central orifice I by means of a screw thread. The hollow which is left in the projectile in consequence of the hollow tube H is afterwards filled up with a fine steel plug and cap. If, however, it is desired that the cooling pipe H shall not form part of the projectile, the pipe H may be surrounded with some woody fibre, which will become charred when the metal is poured into the mould; the same object may be also attained by making the pipe of silicious or other refractory material. Four claims are made.—No. 6058. April 26th, 1887. 8*d*.

ELECTRICITY.

Dynamos.—*A. M. Clark, London.* (*L. Maiche, Paris.*)—In the machines designed by the inventor, both the armature coils and the field magnets are fixed and do not revolve, and the development of the induction currents in the coil is due to the motion of an iron armature core, which passes freely through the coil, and is presented alternately to the different poles of the field magnets. The mass of the revolving parts is thus reduced, and

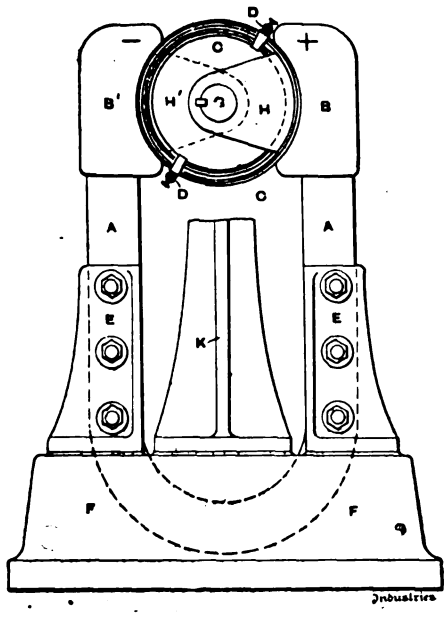


Fig. 1.

there is no need for any special appliances for collecting the currents. The accompanying figures show the application of this principle to a two-pole machine. A is a permanent magnet provided with pole pieces B B¹, whose interior faces are concaved so as to closely embrace the armature coil C. The permanent magnet is mounted on supports E, and the armature coil is traversed by an iron shaft G, upon which are keyed the sector-shaped blocks of iron H H¹. The successive changes of polarity of the shaft G and its appendages, when they are rotated by means of the drum I, will have the effect of inducing currents in the coil C. The permanent magnet may be replaced

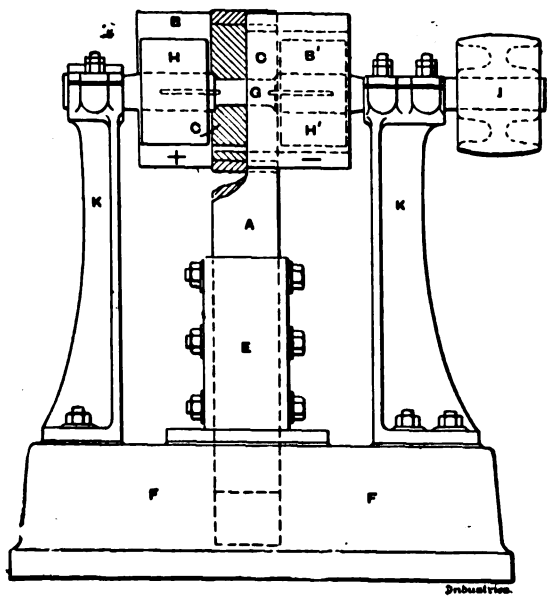

Fig. 2.

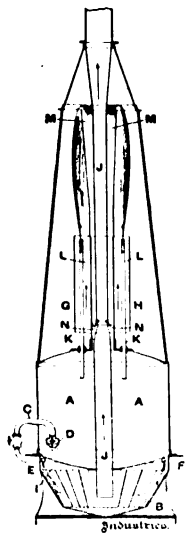


by an electromagnet if desired, and the shaft may be fixed while the blocks H H¹ constituting the armature proper rotate; in the latter case the shaft G is made hollow, and is traversed by another shaft which carries the two blocks. In order to avoid the creation of Foucault currents in the armature, the core and the blocks H H¹ are slit in any plane passing through the axis. When electromagnets are used to excite the field, it is essential that the current should be rectified. For this purpose a circuit is led from the terminals of the machine, and carried to the two extremities of the wires of the field magnets. A voltaic cell is introduced into this circuit, and is composed of a strip of copper and a strip of aluminium immersed in acidulated water; such a cell permits the passage of currents in one direction only. Two claims are made for the machine in which both the field magnets and armature coil are stationary, and the current generated by the motion of an iron core traversing the armature coil and moving in the magnetic field, and for the method of exciting the field electromagnets by rectifying a portion of the current.—No. 5958. April 23rd, 1887. 8*d*.

Secondary Batteries.—*E. Julien, Brussels.*—The electrodes are made of metallic inoxidisable plates which form the supports for the active matter. The component elements of the alloy used in making the plates consist of ninety-four parts of lead, four and a half of antimony, and one and a half of mercury. To the liquid generally used the inventor adds a variable quantity of sulphate of magnesia in order to increase the efficiency of the pile. In each element the electrodes of the same kind are connected by means of a conductor of the same alloy as is used in the construction of the plates, but its composition is slightly altered in order to increase its rigidity; and in a battery the elements are connected by similar conductors. Sixteen claims are made.—No. 8855. June 20th, 1887. 11*d*.

MISCELLANEOUS.

Dust Collectors.—*W. P. Thompson, Liverpool.* (*The Knickerbocker Company, Jackson, Michigan, U.S.A.*)—The air laden with dust or shavings is propelled through a carrying tube by means of an ordinary fan, and conveyed to a wedge-shaped box. The current of air enters at the broad end of the box, and at the narrow end there is an opening into a closed dust box; the upper side of the box is provided with deflecting plates, and with an exit pipe for the purified air. The contraction of the passage due to the wedge shape of the box causes the current to increase in velocity; the suspended dust is therefore shot into the closed receptacle. Six claims are made.—No. 2656. February 22nd, 1888. 8*d*.

Hydrocarbon Lamp.—*B. H. Thwaite, Liverpool.*—The liquid hydrocarbon is forced out in a jet, by means of a current of air or steam which has been heated in a regenerative chamber above the flame. The heated air is also used for the combustion of the oil. One form of apparatus described in the specification for carrying out this method is shown in the accompanying figure. The liquid hydrocarbon in the vessel A is volatilised by the combustion of part of the oil in a cone-shaped combustion chamber B, which has a corrugated side, and is provided with slitted air

openings. The oil, which is syphoned from A by means of the pipe C, flows along a circular distributing pipe I, and streams through perforations in its lower side on to the side of the combustion chamber and down its corrugations. The air to support its combustion enters through the air spaces between the corrugations, and the products of combustion pass through the centre by means of the chimney J. The combustion of the oil generates heat, and soon volatilises the liquid hydrocarbon, and the resulting oil gas passes through the burner tubes K. The tubes are surrounded by an annular space L through which the air ascends. The flame projects to the upper edge of the annular space L, and descends through this space to the position N, where it is drawn into the chimney by aspiration. Two claims are made for the various modifications described.—No 6652. May 6th, 1887. 8*d*.

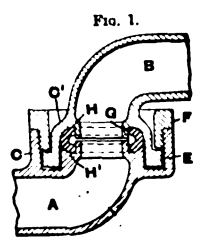
Measuring and Controlling the Supply of Water.—*O. Brown, London.*—This invention relates to the apparatus described in Patent No. 13228 of 1886. A measuring vessel constructed according to the improved method is formed of sheet metal, and consists of three parts, viz., a central division plate and two body pieces, which form the sides and bottom of the compartments. For regulating the escape of water temporarily confined beneath the loaded compartment, the space between the floor of the tray and the bottom edge of the central plate is varied. By reducing the knife edges the oscillating measuring vessel is lowered in the tray, and the bottom edge of the central plate is brought nearer to its floor; the passage for the water from one end to the other of the tray is thus restricted and the action of the apparatus regulated. By lowering the measuring vessel the angle of oscillation is diminished, and a smaller amount of water serves to overbalance it. For the purpose of cushioning the loaded compartment in its fall, each compartment may be provided with a false bottom open at the sides and closed at centre; when the charged compartment falls, air is temporarily confined between the under side of the compartment and the false bottom. In order to allow the counter to be changed readily, the inventor employs a fork-shaped clip whose loop engages with a rod operating the counter and whose arms embrace the central division plate of the oscillating measuring vessel. To keep the supply orifice free from obstruction, the supply nozzle is placed vertically, and is provided with a valve seat at its upper extremity. To the valve, which rests upon the seat, is attached a pendant wire extending downwards through the supply passage. When the valve is lifted the wire is raised, and tends by its movement to free the passages from any accumulation of dirt. Seven claims are made—for the false bottom, for the variation of the angle of oscillation, for the means of detaching the counter, and for the pendant wire.—No. 8632. June 15th, 1887. 8*d*.

Cleaning Carding Engines.—*C. de Hemptinne & F. de Hemptinne, Ghent, Belgium.*—The object of this invention is to clean the cards by mechanical means instead of by hand. A friction wheel is turned by contact with the loose pulley on the shaft of the main drum, and on the shaft of the friction wheel is fixed an eccentric, which by means of a bent lever transmits a rocking motion to a crank; on the crank is keyed the spindle of a vibrating comb, which acts upon the card cloth in the same way as the hand cleaners. By means of mitre and worm gearing the shaft of the drum is caused to rotate slowly during the cleaning process. A vertical screw threaded rod is passed through the support which carries the whole of the above described gearing, and a hand wheel is fixed to its upper end. The rotation of this hand wheel is transmitted by suitable gearing to two spur wheels, which gear with two toothed segments moving in grooves and carrying a sliding panel of the outer casing of the main drum. On one of these two shafts a spur wheel is fixed, which gears with a pinion on whose shaft is mounted another spur pinion gearing with a vertical rack. On this rack is fixed a laterally projecting pin which, when the rack is lifted, raises the lever and disengages the latter from the lever of the comb. On turning the hand wheel the friction wheel is removed from contact with the loose pulley on the shaft of the drum, while the pin of the vertical rack lifts the bent lever and disengages it from the lever of the comb. Three claims are made.—No. 8422. June 11th, 1887. 8*d*.

GERMAN PATENT ABSTRACTS.

Pipe Coupling.—*M. Schleifer, Berlin.*—This invention relates to a pipe connection which allows the pipes to be slewed through a complete circle. The pipe A is provided with a socket C, into which the ring shaped end E of the pipe B fits. The ring E may either be cast in one piece (Fig. 1) with B, or cast separately

Fig. 1.



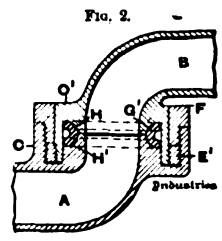


Fig. 2.

and screwed on to B (Fig. 2). After inserting an india-rubber packing G (Fig. 1), if the pressure in the pipes exceeds the outside pressure, or G_1 (Fig. 2) in the reverse case, into recesses H H¹ in A and B respectively, a ring F is screwed into the socket, thereby pressing E downwards and completing the joint.—No. 42518. 6th February, 1887.

Filters.—*H. A. Flebbe, Bergedorf.*—This invention relates to a filter for lubricants. The apparatus consists of a cylinder surrounded by a steam or hot water jacket, and provided with four filters shown in Fig. 1. These filters are secured to the

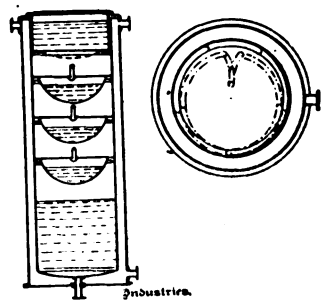

Fig. 1. Fig. 2.

cylinder by expanding rings shown in Fig. 2, and this arrangement allows the filters to be exchanged and cleaned. The lubricant, which is kept liquid by the heat of the steam jacket, penetrates the four filters in succession, and is collected in the bottom of the cylinder.—No. 42306. 24th March, 1887.

The full specifications of the British and United States patents, and the Official Journals of the German Patent Office, from which the above abstracts have been compiled, and the Official Journal of the United States Patent Office, may be seen by subscribers and clients at the Reading Room, Manchester Office of Industries, *where also Patent Indexes from* A.D. 1617 *may be consulted. Copies of the British specifications may be obtained on application to* H. Reader Lack, Esq., *Comptroller-General, Patent Office, Southampton Buildings, London, W.C. The published price must be remitted, together with a sum sufficient to cover postage, which may be reckoned at ½d. for every* 10*d. or fraction of* 10*d. Remittances exceeding one shilling must be made by Post Office Order.*

DUCRETET'S OIL FILTER FOR GAS ENGINES.

Gas engines are generally lubricated too abundantly, especially if it be necessary for the attendant to leave the engine for a longer or shorter time without supervision, in which case he prefers to arrange for an excessive supply of oil rather than run the risk of a breakdown owing to insufficient lubrication. In consequence of this state of things, the quantity of oil which passes through the engine is far greater than that required to insure all the bearing surfaces remaining in good condition, and it becomes a matter of importance to be able to use the oil over again. This, however, cannot be done without careful filtration, and for this purpose M. E. Ducretet, of 75, Rue Claude Bernard, Paris, has devised a special apparatus to be attached to gas engines, in which the oil coming from the cylinder is filtered hot. The manner in which the apparatus is attached to the engine will be seen from Fig. 2, where C represents the cylinder of the gas engine, and G G the exhaust pipe round which is placed the filter. The used oil is poured into the funnel at the top until a drop of oil appears at the spout *e*, showing that the filter is full, and the filtered oil is drawn off through an ordinary stop cock into a can beneath. The details of this apparatus will be understood by reference to Fig. 1. By placing the filter round the exhaust pipe, the heat of the escaping gases is utilised to raise the temperature of the oil under treatment, which greatly facilitates the process. The filter itself is contained within an outer vessel coated on the outside with some non-conducting covering. This outer vessel is traversed by a tube T, and forms an oil bath, the tube having for its object partly to render the vessel independent of the exhaust pipe, and partly to prevent the oil in the bath from being injured by the excessive heat of the exhaust tube. The filter consists of a cylindrical vessel, having the spout *e* already mentioned and a loose cover P which can be screwed down by the thumb nuts *b*, so as to compress more or less, by means of a hollow central tube and perforated plate, the filtering medium M, which is generally composed of compressed cotton. The grosser impurities are retained by the perforated plates *r*. The oil from the bath can be drawn off by the plug *d*, and a vent hole *o* is provided at the top to allow for expansion. We learn from the inventor that one of these filters has been in constant use at his own works during the last nine months, and has resulted in a great saving of oil.

PROFILING MACHINES.

In carrying out the various functions of milling or machining metallic surfaces by a rotary cutter, profiling or milling with the aid of a "former" has not played such an important part in modern workshop practice as its merits seem to deserve. This arises from various causes: (1) A disinclination to discard existing practice and obsolete methods; (2) a conservatism on the part of the mechanic in the matter of working with labour saving machines; (3) a fallacious idea that a multiplicity of the same work can only render such machines profitable.

At no period in this country has the necessity arisen for the substitution of machine for hand labour more than at the present time, as competition is extremely keen in every branch of engineering, and our foreign competitors have certain advantages: among others their longer working hours. It is therefore incumbent upon those who undertake the practical management of workshops to use every means they can to minimise the cost of manufacture of the details of the various machines, and be fully alive to the improved methods of working which a perusal of the leading mechanical journals generally affords. It is astonishing to find the pertinacity with which men will cling to the use of machine tools made forty years ago or longer for machining irregular shaped objects. A general opinion held by a great many skilled workmen is that improved methods of working lead to over-production; but it is only by the systematic removal of obsolete machine tools, that long standing firms have been enabled to keep up their past reputation, and compete with younger firms who have an installation of modern tools.

As regards the application of the profiling machine to ordinary machine shop work in which planing, shaping, and slotting machines are now generally used, we may state that much misconception exists as to its advantages, as some think it a machine much overrated by its makers, and, therefore, it becomes difficult to induce many engineers to overcome their prepossessions and substitute profiling or milling machines where their work will well admit of it. A profiling machine is at its best where a multiplicity of the same work is operated upon; but even taken under its worst conditions—for instance, machining straight flat surfaces—the cost of production is much cheapened; but where the work is irregular a still more favourable result is produced. One important condition that a labour saving machine should fulfil is that little or no hand labour should be requisite after the object is machined, and no machine fulfils this better than the machine under notice. A rigidly constructed profile machine, with a cutter of proper form and running at the proper speed, will impart a surface which requires no file finish, with great economy of production. It will, we think, be conceded by those who have had experience in this direction, that far less mechanical skill is required in operating profiling machines than slotting or shaping machines. The cutters used, of course, require skilled labour in their production and maintenance; but then one man can attend to these for a number of machines producing high class work with low priced labour. There are one or two features in the design of the profiling machine, when applied to some branches of engineering, which require some modification. For instance, in a heavy class of milling or profiling it is advantageous to dispense, as far as possible, with gearing for driving the cutter spindle, and substitute large driving pulleys with a good width of belt; for by this means a far cleaner cut is produced, and one that requires little or no labour upon it after leaving the machine. Of course, very heavy machines will require to be geared; but any device which provides an efficient substitute does much to insure its success as an efficient labour saving machine—better, in fact, than all cut gears or other refinements of manufacture. The framing of machines of this type should also be constructed with plenty of metal to increase their rigidity, and prevent vibration as much as possible. The circular, longitudinal, and transverse tables should all be capable of manipulation from one point, so that the operator may have complete control over them. They should run upon square ways to reduce the friction, and have water troughs formed around them, and an effective drain for the lubricant used. An important feature is an efficient means of lubrication for the milling cutter; for upon this the success, when taking a heavy, rough cut, in a great measure depends. Many machine tool makers employ a small centrifugal pump, which draws its supply from a well contained in the frame of the machine, and into which the lubricant from the tables is drained. This pump must necessarily be driven at a high rate of speed to maintain an efficient head, and is often a source of trouble to the operator. A more effective arrangement, we think, is a small force pump, supplying a tank fixed at a convenient height above the machine; for by this means a pressure may be obtained sufficient to keep the cutter perfectly cool, and effectually remove the cuttings or dirt. There seems to be some diversity of opinion regarding the design of a profiling machine for doing heavy work in connection with its spindle bearings. It is thought by some machine tool makers that the perfect alignment of a spindle can only be properly effected by adjustable cone bushes, with lock nuts. On the other hand, others contend that a parallel bearing with ordinary brasses is equally effective. It is not our present object to discuss the merits or demerits of each system; but in deciding the claims of one or the other, the class of work to be machined should be taken into consideration. In heavy milling it has been found desirable to adopt a large diameter bearing at the nose end of the spindle, with a length about double that of the diameter. In such cases this bearing is made parallel as well as that at the tail end, which is backed up by a hardened steel tail pin to receive the end thrust. Bearings of this kind are more adapted for end milling than those in which the spindle is coned and adjusted by means of taper bushes and lock nuts. Very little trouble is given by this class of bearing, whereas with cone bearings it is sometimes otherwise. An effective attachment now usually supplied with heavy machines is an additional outer bearing for the spindle, which is made portable, and can be readily detached when the cutters require removal. Of the various types of smaller profiling machines, the vertical single spindle type is generally useful because of its wide application. In this machine the spindle is carried on a frame, sliding on guides affixed to two vertical standards. This frame is moved in a horizontal plane by a lever moved by the operator. The table for holding the work moves in the same plane, but in a longitudinal direction, and is operated by a hand wheel at the side of the machine. It is important in this type to have the spindle frame easy of movement, and yet quite free from slackness. The table is generally moved by means of a rack and pinion, the pinion being built up of two discs, connected together with an arrangement for adjustment to prevent back lash between the rack and pinion. The bearings in this type are generally made with cone bushes, as end milling is rarely required. The spindle is usually of wrought iron case hardened, coned for each bearing, and arranged to run in hardened steel bushes, which are set up with lock nuts. This is a somewhat expensive machine to make; but a bearing of this kind is very durable and easy of running. In almost every case for which this machine is adopted, a former or copy piece of the object milled is usually employed. If the number of the objects to be machined will allow of it, this former is fixed to the table along with the work to be operated upon; and a tracer pin, arranged at a convenient distance from the cutter and carried in the same frame, is either held against the former by means

DUCRETET'S OIL FILTER FOR GAS ENGINES.

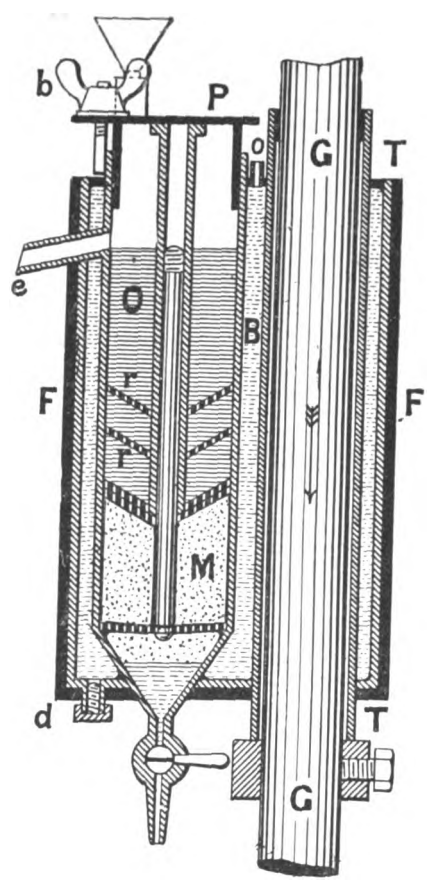

Fig. 1.

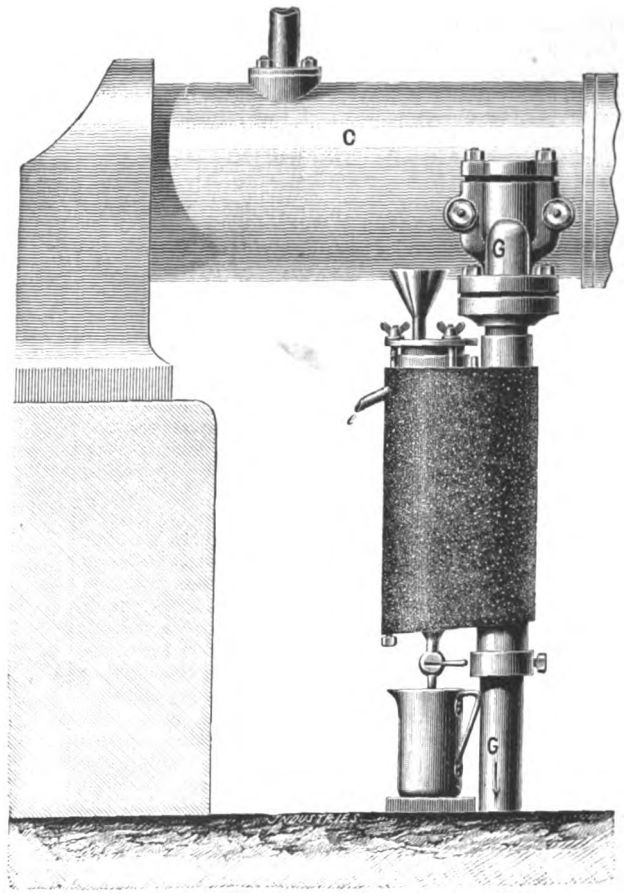

Fig. 2.

Digitized by Google

of a suspended weight in the frame or by the operator; so that by the combined movement any object, however irregular in one plane, can by the aid of the former be effectually milled. The tracer pin is usually made taper, so that any reduction in the diameter of the milling cutter, due to wear or sharpening, is allowed for by the vertical adjustment of the tracer pin. There is a limit, however, to the utility of this type of machine for general purposes, as the object milled and the former or copy necessarily limit the table space, and confine the machine to a small class of work. This has been obviated in some measure by placing the former directly over the work milled, and by using the cutter spindle as a tracer pin.

We may now briefly refer to milling cutters, as the care exercised in their production is so essential to the success of profiling machines. There is perhaps no branch of workshop practice in which false economy is better shown, than in placing the manufacture and maintenance of cutters into the hands of unskilful workmen. It is difficult to lay down any hard and fast rule for hardening and tempering cutters, as it is only by long experience that success is attained. Many workmen favour the use of the lead bath for hardening—as they assert that there is less liability of the cutter springing—which is generally used in combination with tepid water having a film of oil on the top of it. On the other hand, some prefer a good clear fire, and a bath of slightly warmed salt water. In the construction of plain cutters it is not advisable to make them of larger diameter than is sufficient for the work. The teeth should be fairly coarse, which renders them less liable to clog, and allows a quicker feed. It has long been considered good practice to have the teeth cut spirally, and in that way diminish the cutting contact along the surface when starting. A step marking a distinct advance in this method of cutting, and which is now adopted for heavy work, is that of cutting a coarse thread upon the periphery of the cutter. This gives greater freedom to the cuttings to get away. Various means are adopted for connecting the cutter to the machine spindle, and perhaps that most usually adopted is to turn the shank end parallel, and secure it by a set screw which is screwed into the nose of the spindle. This method is objectionable, however, as the cutter almost invariably runs out of truth. A superior arrangement, and one which more readily facilitates interchangeability, is to screw the nose of the spindle externally, and bore in it a hole with a large taper, and place therein three split dies. These receive the shank end of the cutter, and are held in position by an hexagonal cap nut, internally flanged at the lower end, and arranged to screw on the nose of the spindle.

THE TAY VIADUCT.

At the ordinary meeting of the Institution of Civil Engineers, held on the 8th ult., the first paper read was on "The Tay Viaduct, Dundee," by Mr. Peter Crawford Barlow, B.A., M.Inst.C.E. The author stated that this viaduct, which carries a double line of railway over the Firth of Tay at Dundee, was built to replace the former bridge, part of which was destroyed during the memorable storm of December 28th, 1879. The viaduct was 10,527ft. in length, and of this a length of 7397ft. was straight and parallel to the straight part of the old bridge, the centre lines of the two works being 60ft. apart. At the southern end the lines of railway branched westward towards St. Fort, and eastward towards Newport, the junction being made upon brick arching of sufficient width for two double lines of railway. The northern or Dundee end of the viaduct formed a curve of 21 chains radius, and joined the existing railway, which was here parallel to the river. The gradient of the line was 1 in 762, falling from the southern shore to the navigable channel, where four spans, each with a clear headway of 77ft. above high water spring tides, were provided, and from this point a down gradient of 1 in 113·75 was maintained to the northern end. Out of a total of eighty-five piers, the foundations of seventy-three were formed of a pair of cylinders placed from 32ft. to 26ft. apart from centre to centre. In the case of the largest spans, the cylinders, which were of wrought iron, were 16½ft. in diameter at their upper ends, and were enlarged by means of conical sides to a diameter of 23ft. at their bases. With these areas the total weight of the structure and rolling load combined produced a pressure of from 3 tons to 3½ tons per square foot upon the foundations. Special pontoons were constructed by Mr. Arrol, the contractor, for the purpose of affording a stationary platform from which to conduct the operations of sinking the cylinders to the required depth into the river bed—an illustrated description of these pontoons was given in *Industries*, Vol. II., page 525. The platforms, which carried all the necessary machinery—steam cranes, dredger, winch, concrete mixer, hydraulic and centrifugal pumps, diving gear, &c.—consisted of rectangular iron tanks, fitted at the four corners with cylindrical legs resting on the bed of the river, each leg having two hydraulic rams by means of which the platforms could be raised or lowered at will. In the centre portion of the platform, the surface of which was maintained at a height of about 2ft. above high water, two rectangular openings were provided to admit the cylinders in their respective positions. The cylinders were prepared on shore in annular divisions, of a size that could be easily handled and conveyed to the pontoons, where they were bolted together. The excavation was then proceeded with by dredging the sand from the interior, and, when necessary, additional weight in the form of cast iron blocks was added to force the cylinder down to the required depth. The whole was finally filled with concrete, composed of six parts of gravel and sand to one part of Portland cement, passed through the water in specially designed hopper boxes. The internal circumference of the cylinder had previously been lined with a ring of brick work 18in. thick, in order to add weight and stiffness during the sinking operations. The foundations were mainly upon sand, but at the shore ends rock and red clay were found. At this stage of the work, the cylinders being about 1ft. above low water, the pontoons, which admirably resisted the force of the gales so prevalent in this part of the Tay, were floated away to the site of the next pier. According to the requirements of the Act of Parliament, the foundations were tested with a weight 33 per cent. in excess of the possible dead and live loads combined, and for this purpose thirty thousand cast iron blocks, each weighing half a ton, were required. The result of these tests, which were personally checked by Major Marindin, R.E., on behalf of the Board of Trade, were very satisfactory, the greatest depression recorded being rather under 1¼in. for a ton per square foot. The whole of the seventy-three piers formed with cylinder foundations were subjected to this test, the aggregate weight representing 92,000 tons. The remaining piers on the north and south shores were of brick work, and adapted to the requirements of the situations in which they were placed. After testing, the piers were continued by brick cylindrical shafts filled with concrete, and to protect the brick work from the action of the tide during construction, the work was enclosed in temporary iron caissons. At 18in. above high water the two brick shafts were joined by a horizontal member of brick work and concrete resting on cast iron girders. This connecting piece was 7ft. deep, and carried at the lower part a string course of granite running round the pier. Upon each brick shaft an octagonal iron frame was secured by eight wrought iron tie bolts, each 2½in. in diameter and 20ft. in length, anchored down into the brick work by cast iron plates. These frames, which served to distribute the weight uniformly over the brick shafts, formed the base to which the superstructure of the pier was riveted. Maintaining the octagonal form, two hollow pillars were constructed of plates, stiffened by horizontal bracing internally, and by vertical T irons and channel irons externally, and were united at the top by a semi-circular arch. The mean stress upon the iron work of the piers was about 2 tons per square inch.

After a careful examination of the girders still remaining on the old bridge, it was decided to use them in the new viaduct, placing them on the outsides under the parapet, and adding to each span two new intermediate girders. To transfer the old girders to the new piers, special pontoons with telescopic columns, actuated by hydraulic rams, were used. The columns were adjusted to the under side of the span to be removed, the rising tide completed the lift, and the whole was floated across to the new piers, which were adjacent and opposite to the old ones; when in position the old girders served as a platform on which to run out the new girders. Rails having been laid on the top members of the old girders, the new ones were brought out on travellers designed for the purpose, and finally were lowered into their places by hydraulic power. The large girders forming the thirteen spans in the central portion of the river were built upon a staging near the south shore, and as each complete span was finished, it was floated on pontoons and landed upon the brick work portion of the piers already prepared to receive it. The entire span, weighing about 514 tons, was afterwards raised by hydraulic machinery to the full height, the superstructure of the piers being completed as the work proceeded. These girders, of which there were two to each span, were 245ft. in length, of "hog back" form, 20ft. high at the piers, and 29ft. high in the centre. They were connected by bracing 16ft. above the rails, and by flooring, which was built up of plates and channel irons, forming a corrugated decking 16in. deep. The flooring of the smaller spans of the viaduct was of a similar type; but instead of channel irons, single steel plates were pressed into a trough form, 8in. deep, with a length equal to the width of the viaduct, 25ft. 6in., and riveted to each other by a cover plate joint. Above the decking throughout the whole length of the viaduct, a parapet of lattice work was riveted to the outside girders, and between it and the rails timber guards were placed, hollowed out to receive on one side a 9in. water pipe, and on the other a gas pipe and telegraph wires. Provision was made for the effects of expansion and contraction at about every 500ft. on the straight part of the viaduct, and in the permanent way there were corresponding fished expansion joints. Between the expansion joints the girders were connected together in groups. To provide against any possible tendency in the girders to travel in the direction of the gradient, at thirty-eight places along the viaduct the girders covering one span in each group were firmly bolted down to two piers. The total expansion provided for was about 5ft. in the length of the viaduct. The rails of the permanent way were laid in chairs upon cross sleepers, the sleepers being embedded in ballast in the corrugations of the decking. The actual work in the river was commenced in June, 1882, and the viaduct was opened for public traffic on the 20th of June, 1887.

The second paper read was on "The Construction of the Tay Viaduct, Dundee," by Mr. Wm. Inglis, Assoc.M.Inst.C.E. Referring to the difficult character of the work, the author stated that the bridge across the Tay was probably the longest in the world over water, and for a considerable distance operations had to be conducted at a point in the river which was navigable for vessels of considerable tonnage. Seventy-three of the eighty-five piers in the structure were cylindrical in groups of two for each pier. The shafts, as sunk into the river bed, were formed primarily of wrought iron cylinders, built in annular sections. The first section was provided with a cutting edge which sank into the river bed as the superincumbent weight was added. The cylinders were filled with concrete, which formed a compact shaft encircled by an iron tube. The sinking of the shafts was accomplished by means of platforms, composed of five water tight tanks, two long lateral tanks being connected by three short ones, the intervening spaces being left open. Through the open spaces or wells the cylinders were sunk and filled with concrete, the distances being exactly measured, so that the centre of the well coincided with the centre of the shaft. Columns or legs were passed through apertures at the corners of the platform, their extremities resting on the river bed, and their shafts being fitted with pin holes, by which the height of the platform could be regulated. The apparatus on each platform was an engine and boiler for actuating the hydraulic and other pumps, workshops for the repair of tools, two 10-ton cranes, one 3-ton crane, a concrete mixer, and a centrifugal pump. The stage was raised or lowered by hydraulic gear, consisting of a cylinder 12in. in diameter, piston, piston rod, open cross head, and the necessary valves. When the platform was to be floated from one pier to another, it was lowered to catch the tide two hours before high water. Ropes were carried from one side of the stage to the piers of the old bridge, and to three heavy anchors on the other. The steam crane was used as a winch, and when the platform had been brought to its new position the legs were lowered down and fixed. The foundation cylinders were riveted together on shore, the various rings being lifted from cargo boats, and placed in position by the 10-ton cranes. The first ring was formed of ⅜in. wrought iron plates, 23ft. in diameter and 13ft. 4in. deep; above this was the taper 7ft. deep, and then the upper portion 18ft. 6in. in diameter. Each added ring was bolted through an internal flange to the preceding one, and these were lined with brick work in the upper portion, and lowered to the bed of the river by hydraulic jacks. The method of placing the cylinders was as follows: Steel links, bolted together in single and double lengths, were passed through the hollow trunk, cotter holes being formed in each link at a pitch of 10in. A bow was fixed on the top of the hydraulic jacks, through which the links were passed, while they were securely bolted to the lower portion of the foundation cylinder. The jack was then brought into action, and by the use of cotters to graduate its descent, the cylinder was sunk to its appointed place, the internal brick work assisting to sink it.

The excavation was accomplished for the most part by a steel digger of the Milroy pattern. This implement, however, was found ineffectual where silty sand had to be lifted, and another process was successfully attempted. Two flexible hose pipes, each 6in. in diameter and 20ft. in length, were placed in the bottom of the cylinder, the ends being brought together and joined into one 12in. pipe leading to the pump on the platform. A diver was then sent down, who manipulated the suction pipes, so that whilst the one threw up sand the other kept the pump free by drawing clean water only. As much as 40 cubic yards had been pumped up in an hour, giving a subsidence of over 2ft. in the cylinder. The cylinders having reached the proper depth, and the interior having been cleaned out to the cutting edge, the concrete was then put in. Tipping measure boxes, filled with gravel and the necessary proportion of cement, were lifted to a staging erected above the concrete mixer. The revolving casing of the mixer was square in section, thus insuring more thorough mixing. The receiving boxes were fitted with hinged hopper bottoms, so that when lowered into the cylinder the concrete was deposited on touching the material already in position. When the concrete was level with the flange carrying the brick work, the diver packed it carefully underneath. The same process was followed in filling the twin pier.

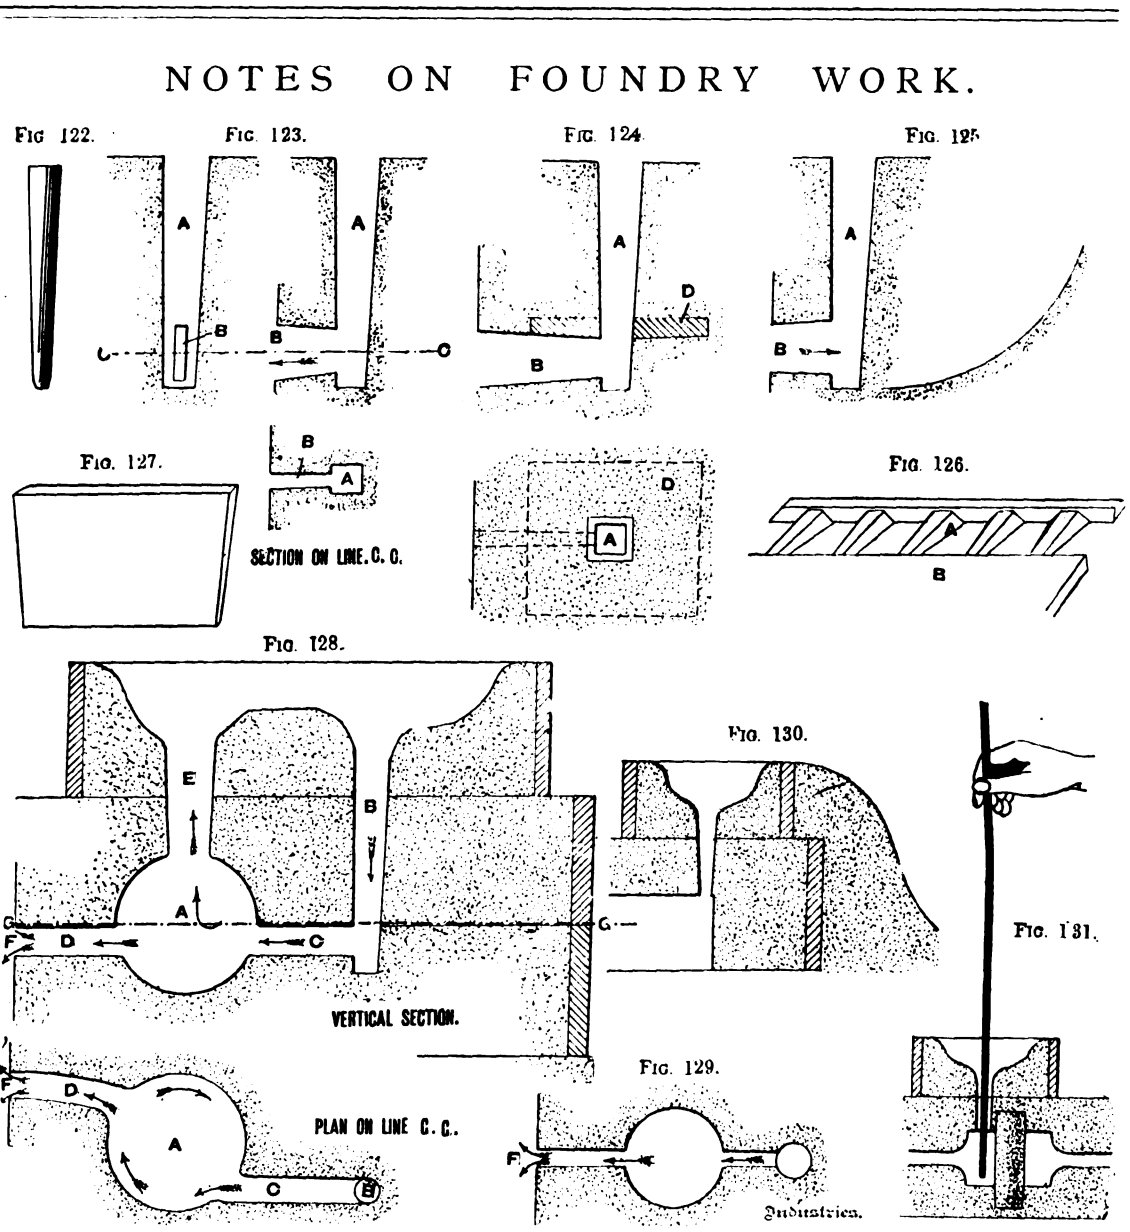
In founding the seventy-three pairs of cylinders from the platforms, the following quantities of material were handled, viz.: 2300 tons of wrought iron cylinders, 680 tons of temporary caissons, 26,000 cubic yards of excavations, 65,000 cubic yards of brick work, 27,000 cubic yards of concrete, and 22,000 tons of cast iron blocks to weight the cylinders. The superstructure of the piers consisted of two hollow octagonal pillars connected by a semi-circular arch. Each pillar was temporarily erected at the works in Glasgow, partially riveted there, and the various parts marked for re-erection. The pillars were placed in position by using one of the movable platforms already described, from which all the apparatus had been removed, and a 5-ton steam derrick substituted. This was only necessary at the south side of the river, where the viaduct was highest, the gradient of the bridge at the north end permitting the use of boats with special derrick cranes instead of the platforms. The shallowness of the water on the sand banks necessitated rapid working at the latter point, and the majority of this work at the north end was erected during portions of three tides, or a total of twelve working hours. The riveting was effected afterwards from a platform of light lattice girders, suspended on each side of the pier, which also served for use in painting the structure.

The lattice girder work of the old bridge formed part of the roadway of the new viaduct. The girders were removed from their old position by floating them upon two large iron pontoons, 80ft. by 27ft. 6in. by 8ft. deep, stiffened internally by lattice girders and water tight bulkheads. These were bound together by girders, upon which lattice columns were erected, fitted with telescopic portions that could be adjusted to any required height. The pontoons were floated at low water underneath the girders to be removed, and as the tide rose the telescopic girders were pushed up, and securely pinned to the main column. At full tide the girders were free from the old bed plates and clearly afloat, and by manipulating mooring ropes, the pontoon was drifted to the site of the new bridge, a distance of 60ft. On reaching its intended position the hydraulic rams, which had raised the girder from the old piers, were opened, and the span was allowed to drop into its place on the new structure. The curve of the bridge at the north side of the river prevented this method from being adopted there, and the girders were transferred from the old to the new piers by means of travelling steam cranes.

The new girders were built in the yards adjacent to the railway sidings on each side of the river, the riveting being done by hydraulic machinery. To bring the girders into position, two travellers were constructed by which each completed girder was transferred to the line of rails, and carried to its position. A locomotive engine attached behind pushed the travellers with their burden forward over the completed work, and the girders were thus carried to their destined positions. The large spans were intended at first to have been erected from staging suspended between the piers; but it was ultimately decided to erect them on shore at the south side of the river, and to float them out to their positions. A timber jetty, 400ft. long by about 100ft. wide, was erected, and provided with two docks capable of admitting

Digitized by Google

pontoons, by which the girders might be floated. Temporary rails were laid, so that cranes might travel along the whole length of the girder while in process of erection. The bottom booms were first laid down and riveted, the struts, ties, and parapets were next dealt with, then the top booms were placed and riveted, and afterwards the top cross bracings and wind ties. When the girder was completed, the temporary flooring of the docks at each end of the jetty was lifted, and the pontoons were introduced. During the rising of the tide the pontoons were adjusted, and after the weight of the span, 514 tons, had been transferred to them, the girders were lashed round the pontoon stools. When free and afloat the pontoons were taken in tow by four steam tugs, and towed down the river for some distance, so as to catch the flood tide, which floated them to their positions between the piers. When placed at the spots which they were to occupy, the pontoons were partially sunk, so as to be free of the girder, and were towed back to the dock to repeat the operation. The large spans being now ready at the base of the pillars, had to be raised to the level of the viaduct. As the end posts of the girders passed through the side of the pillars several plates were necessarily left unfixed, whilst the others above them were only temporarily bolted. Eight steel angles, in pairs, were attached to a sole plate bedded on the top of the pier, and placed at right angles and exactly vertical. These were held together by bracing bars, forming a frame work carried to the top of the pier. These formed a channel in which the end of the girder was raised by means of hydraulic jacks, cotter pins being inserted in successive holes in the frame work, as the end of the girder was elevated. Underneath each end post, inverted hydraulic rams were bolted to the flanges of the bottom booms, and cross girders were placed across the frame work, which were secured to the columns so that the rams might thrust from them. The hydraulic power was so regulated that it could be applied to the ends of the girder alternately. In this manner the span was lifted at one end 15in. in two lifts, and the operation was repeated till the top of the pier was reached. The plates which had been removed from the superstructure of the piers to allow of the passage of the girder were fixed and riveted immediately after the span had been raised. The girders rested temporarily on the permanent cross girders of the pier, thus enabling the lifting columns and bracings to be removed to another pier, and again erected for use. The bed plates and rockers were inserted whilst the girders were thus temporarily raised about 6in. above the finished level of the bridge. The flooring, which had been left incomplete until the spans were in position, was then finished and left ready for asphalting and laying for the permanent way. Most of the machinery used in the erection of the bridge was specially designed by Mr. William Arrol, the principal member of the firm of contractors, and the success which attended the work was the best testimony to its efficiency.



NOTES ON FOUNDRY WORK.

By the Author of "Pattern Making."

(Continued from page 417.)

XV.

Gates, Risers, and Feeding.—The question of the manner in which the metal is to be run is a matter of great importance, and at the same time that the moulder examines his pattern to see how it must be rammed, he decides on the method of pouring. The metal may be run into the mould from the top, bottom, or sides, from a single runner, or from several, with a single ingate, or with a spray, directly, or through a skimming gate, with or without risers, depending on the individual character of each piece of work. The general principles may be enunciated as follows: Moulds are generally run from the top. Those of considerable depth are often run at the sides, and thin ones are run with a spray from the top, or at the edges. Single ingates are used for heavy castings, and sprays for light castings. In common work the metal is poured directly through the ingate; but a skimming chamber is employed when the casting is required to be very free from dirt. When the surface of the mould is of considerable area, "risers" are used to relieve the strain on the cope, and to afford openings for feeding. The risers must always be of larger area than the runners, so as to obtain the full effect of the pressure. When the character of the mould is such that the metal takes a long time to pass through the ingate, a piece of loam cake should be bedded in to receive the concussion of the iron. To prevent the sand from being cut up and washed into the mould, all sharp corners in the runners and basins must be avoided. We will now take up these points in detail. The common forms of runners are shown in the accompanying figures. For all ordinary kinds of work the round runner stick (Fig. 122) is generally used. The figure shows the average amount of taper given to it. The diameter at the small end regulates the admission of metal into the mould, and the taper is only given to it to facilitate its withdrawal from the sand. The diameters of such runners may vary from ½in. to 4in. or 5in. It is impossible to lay down any hard and fast rules for the sizes of runners; in this matter the moulder has to rely on his judgment. When pouring heavy moulds, it is desirable to pour through several runners, and not from a single large one. Large runners tend to produce local shrinkages in the vicinity, because the metal chills at the top and sides of the runners, and "draws" the casting underneath; and the shrinkage taking place at the hottest portions, the metal becomes porous near the junction of the runner and

casting. When a runner is placed directly over a mould, it can also be used as a feeding head, and then there is no objection to the employment of a large runner. A large runner head is, however, more difficult to cut off cleanly than a small one, and much care has to be exercised in order that a depression shall not be produced on the knocking off of the runner. When the metal is made to enter at the side of a casting, there will be one or more ingates which are connected with a single pouring basin. The forms of the ingates are shown in Figs. 123 and 124. The vertical portion A is the "gate," or "ingate" proper, and the horizontal entry B the "runner." The employment of runners of long narrow section like B entails no risk of the drawing of the casting owing to the mass of metal; they are also more easily and safely cut off than those of large area. The metal falls first into the gate A, and afterwards passes through the runner B; its fall is thus broken, and it enters the mould in a quiet stream. The runner should be placed in such a position that the stream shall pass directly into a rib, and not against a wall of sand, or against a core, which would be apt to become dislodged. Also it is not desirable to introduce a runner into the mould at a level with its bottom, as the metal would be apt to cut up the sand; the gate is only carried down a portion of the depth, and the metal is allowed to fall through a short distance into the mould. This method is illustrated in Vol. III., page 162 (Fig. 16), and page 269 (Fig. 35). If the action of the metal happens to be long continued, then the loam cake shown at D, in Fig. 124, should be inserted. It is occasionally the practice to make the ingate and runner in a core, and to put a corresponding print upon the pattern. This plan is generally costly, and will only pay when there are a great number of castings required. Sometimes a number of flat headed chaplet nails are driven into the sand around the runner just where the metal drops; the metal falls upon these, and the cutting up of the sand is prevented. The same plan is also adopted within the mould, when the metal is poured from the top, and falls to a considerable depth. The horizontal runners shown in these figures can be withdrawn in two ways. In Fig. 123, B is drawn inwards into the mould, in the direction of the arrow. In Fig. 125 it is drawn outwards; a narrow mass of sand is dug away from behind A, as shown by the curved, shaded line to the right, and the runner B drawn in the direction of the arrow; A is then replaced, and the sand behind made good. Very often a mould is filled from both the top and bottom simultaneously. Where iron is poured from the bottom, it rises quietly in the mould, and leaves the surface skin clean and unbroken. But the impurities are apt to lodge under projecting portions, such as cores and lugs. Also in a casting of thin metal there is a risk of cold shots, and the corners are not always sharp enough. When poured from the top, the metal which comes in last is as hot as that which was first poured. In casting cylinders of moderate thickness, which require a clean surface, it is usual to cast from the bottom, in order to obtain a clean bore of equal texture throughout. In deep green sand moulds, it is preferable to run from the bottom, because of the cutting action of the metal on the sand. Also, where there are numerous parts projecting into the mould, it would be frequently unsafe to run from the top. And it should always be remembered that when a mould is run from the bottom, the area of the runners should be greater than when it is poured from the top, because of the greater freedom of entry required in order to overcome the inert mass of metal accumulating above. Moreover, when the metal is run at the bottom, there is considerable liquid pressure against the sand which intervenes between the ingate and the mould; the sand should, therefore, be of ample thickness and well rodded. The runners which are used for thin castings take the form shown in Fig. 126, and the arrangement is then termed a "spray," or sometimes a "sprue." The figure shows a pattern spray A laid against the pattern of the plate B, in readiness for ramming up. This method of ramming up is employed in repetition work, instead of cutting out the runners every time of moulding. The abutting ends of the spray should be thinner than the plate, in order to allow of their being easily knocked off. All thin, light work is properly run in this manner. A casting of large area may have three or four ingates, from each of which will proceed three or four thin runners. Their section is not necessarily identical with that shown in the figure, as they may be

COMPOSITE ELECTRIC BALANCE.

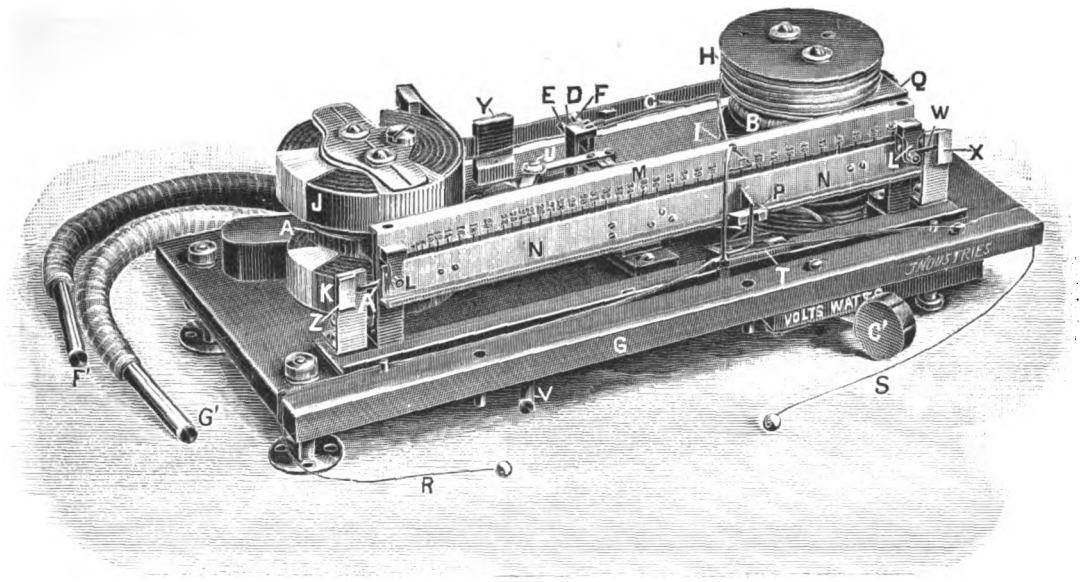

FIG. 1.

semi-circular or semi-elliptical in shape—usually the latter when cut by the moulder himself. For very thin castings, say from $\frac{1}{8}$in. to $\frac{1}{4}$in. thick, the runner stick is of the form shown in Fig. 127, and say $\frac{1}{2}$in., $\frac{3}{16}$in., or $\frac{1}{4}$in. in width, and from 3in. to 6in. in length. The great length is necessary to allow a sufficient influx of metal to prevent chilling. Runners should in all cases be kept as far as possible from those portions of a casting which have to be bored, turned, or faced bright, because the metal in the neighbourhood of a runner is always dirtier, and more open than it is elsewhere. It often happens, however, that a casting has to be machined all over, and in that case there are two courses which may be pursued; one is to allow an extra thickness of metal on the top into which the dirt can collect; and the other is to use a skimming gate. In the first instance the work, if cylindrical, is cast on end, and the ring of head metal so formed is turned off subsequently. In other classes of work, a large number of risers may be placed over the top face, in order to receive the bulk of the impurities. If the surface is quite level, an extra $\frac{1}{4}$in. or $\frac{1}{2}$in. of metal can be allowed over the whole area, and the dirt being spread over this, is afterwards planed or turned away in one or two rough cuts. Each of these methods is commonly practised, but there are numerous cases where a skimming gate is preferable. Fig. 128 shows the arrangement usually employed. A is the skimming chamber, made by ramming up a ball in the mould; B is the ingate, C the runner leading to the chamber A, D the runner passing from the chamber to the mould F. By this arrangement a rotary motion is imparted to the metal immediately it enters the chamber. The metal, impelled by the pressure from behind, passes through D; but the lighter particles remain in the centre of chamber A. If the mould is of small size, the chamber will contain all the dirt; but if of moderate, or of large dimensions, a riser of large capacity must be placed over the centre of the chamber, as shown at E, to carry off the scurf. A ball forms the best chamber, but a flat disc is sometimes employed. The diameters of the ball or disc vary from 4in. to 8in. according to the size of the mould; and if there are two or three different runners, two or three corresponding skimming chambers will be provided. Fig. 129 shows a faulty method in which no rotary action takes place. Risers or "flow-off gates" may, like runners and feeding gates proper, be used for the purpose of feeding castings; but it is always best to consider the function peculiar to them. They are used partly to show when the mould is full, but primarily to relieve the cope of the mould from the strain due to the enclosed air, which is compressed and heated by the rapid entrance of the metal. In filling the mould the metal meets with the resistance of a large body of air, which has no adequate means of exit from the vent, and consequently exerts a considerable pressure on the cope of the mould. But the flow-off gates relieve this pressure, the air passing through the gates as the mould is filled. The metal, though still liquid, exerts no pressure, for the pressure due to the height of the runner is kept in equilibrium by the pressure in the riser, or risers, which are nearly of the same height. When large flat copes are in use the flow of metal will often drive out the air so rapidly as to cut the sand, which, with the rapid heating and drying of the surface, causes damage and scabbing of the sand and drawing down of the cope. In such cases it is therefore the custom to keep the risers closed with plugs of clay, or of dried core sand, until the mould is nearly full, and then to remove them, thereby preventing the scabbing and drawing down. In a large mould there are sometimes as many as four or six risers, each of which is provided with a bank of sand sloping away from the flask, as shown in Fig. 130, and down this bank the metal flows away. In small moulds the riser cups are allowed to simply fill up. Risers are also used as feeding heads. "Feeding" is the supplying of molten metal to a mould to compensate for the loss from shrinkage. Feeding should always be done in the heaviest portions of a casting, such as bosses, lugs, thick flanges, &c. Some founders prefer to cast good heads for obviating the risks of bad feeding, these risks being the knocking down of sand, the shifting of cores, and the blowing of metal near the rods. In feeding several important points have to be observed. One is to make the feeding head large enough in diameter. A head which is so small that the metal will become solidified therein, while that in the mould is still liquid, or in a semi-fluid condition, is useless. It is preferable to have the heads larger than strictly required. The process of feeding is as follows: Just before the metal is poured into the mould, the feeding rods are dipped into the metal in the ladle, and held there for about half a minute, in order to make them white hot and clean, *i.e.*, free from rust, which would cause blowing. Immediately the metal is poured, each rod is lowered gently and carefully into a runner or riser, until its bottom end is felt to touch the mould. It is then raised just clear of this, care being taken not to touch the mould again, and the feeding or "pumping" begins, which consists of a vertical up and down movement, as in Fig. 131, the amount of which is regulated by the depth of the mould. As the metal becomes partially solidified the vertical movement of the rod is lessened, metal accumulates around it, and at every few strokes it becomes necessary to raise the rod nearly out of the feeder head and to detach the metal clinging to its sides.

The subject of pouring basins may fitly conclude this article. Illustrations of these will be found in Vol. III., page 56, Fig. 4; page 162, Fig. 16; page 269, Fig. 35; page 368, Figs. 43 and 48. It will be seen from these illustrations that there is a depression at the spot where the iron is poured out of the ladle, and that the bed rises upwards from this depression, and gently slopes down to the ingates. The depression is made in order to retain the droppings of metal which fall from the ladle during the time its position and angle are being adjusted, and which, if allowed to run at once into the mould, would produce cold shots. When pouring a deep mould from the top, cold shots are often floated up, and accumulate in the upper part of the casting, and are turned off with the head metal. The iron being continually poured into the depression of the basin, falls into a pool of metal instead of upon sand, which would be cut up and portions of it carried down into the mould. The slope of the bed of the basin is towards the ingates, in order to keep the runners well supplied with metal. The space around the ingates is widened, in order to give an area over which the dirt in the metal may be distributed. If this space is too small, the floating dirt is in such close proximity to the openings that it is liable to be sucked or carried down into the mould. For the same reason, the basin is filled during pouring as quickly as possible, and kept full; and the dirt floating on the surface is thus kept as far as possible away from the ingates. The function of the pouring basin is therefore to keep the metal clean, and run a continuous stream into the mould. Any dirt which passes the skimmer will float upon the top, giving the heavier metal time to pass on into the mould. To make a pouring basin after the top flask is in place, the runner pins are put back into position to prevent sand from falling into the mould, and loose sand strewn round them. The iron frame or flask which is to enclose the basin is put on, the frame filled with sand around the runners, and lightly rammed with the pegging rammer. The sand is then loosened in the centre with a trowel, scooped out with the hands, the runners are drawn, and the basin is finished. Should vents from the mould come up underneath the basin, a thin layer of loose hay must be strewn between the top of the cope and the under side of the basin, through which the vents will be brought out.

(To be continued.)

SIR WILLIAM THOMSON'S COMPOSITE ELECTRIC BALANCE.

BY THOMAS GRAY, B.Sc.

A NEW form of electric balance has recently been introduced by Sir William Thomson, which can be adapted either for the measurement of volts, of ampères, or of watts. In the forms hitherto made the range for current is from $\frac{1}{50}$th of an ampère to 500 ampères for continuous currents, and from $\frac{1}{30}$th of an ampère to 250 ampères for alternating currents. The range for volts is, as in all such instruments, only limited upwards by the resistance available; but, as the resistance of the potential coils is about 40 ohms, the lowest potential which can be accurately measured is about 1 volt. These coils are of copper wire, and, in consequence of the high temperature variation of that metal, very high accuracy is not attainable for such low potentials as necessitates the use of the balance without any resistance in its circuit external to its coils. Potentials of from 10 volts upwards may, however, be measured with almost perfect accuracy with this instrument by introducing sufficient non-inductive resistance of platinoid or German silver wire into the circuit. For the measurement of potentials on alternate current systems there should be at least 500 ohms of non-inductive resistance in the circuit.

The general form and construction of the balance will be better understood by reference to Fig. 1. Two coils of silk covered copper wire A B, made in the shape of anchor rings, are fixed to the two ends of a light aluminium frame C, which forms the beam of the balance. This beam is suspended in such a way that the planes of the coils are approximately horizontal, by two flat ligaments, one of which is shown at D, consisting of twenty copper wires, each about $\frac{1}{10}$mm. diam. The suspension ligaments are about 1·5cm. long, and are attached at their lower ends to two insulated brass tubes, carried on a trunnion E, which passes across the middle of the aluminium frame. Their upper ends are attached to round pins F, fixed horizontally, and with their length parallel to the trunnion, in two brass uprights, which are screwed to the sole plate G of the instrument. The suspension ligaments serve the double purpose of forming a flexible elastic joint about which the beam can freely turn, and of conveying the current into and out from the coils fixed to the beam. These movable coils are about 8cm. mean diameter, and the cross section of the ring is about 1 sq. cm. Symmetrically placed with reference to each other and the suspended coil, one above and the other below the coil on the right hand end of the beam, are fixed two coils H I of silk covered wire similar to that used for the movable coils. These coils have about the same mean diameter; but the cross section is rectangular, nearly square, and about 4 sq. cm. in area. Similarly placed with reference to the coil on the left hand end of the beam, are fixed another two coils J K, which are capable of carrying strong currents. When the instrument is specially designed for continuous currents, these coils are made of copper ribbon of sufficient thickness to carry 500 ampères safely. When the instrument is intended for alternating currents, the conductor consists of a rope of thin copper wires, each of which is silk covered to insulate it throughout its length from the others. The ends of all the wires are soldered together; and in order to avoid, as far as possible, error due to irregular distribution of the current across the section, the rope is given one turn of twist for each turn which it makes round the coil. Two turns of this rope is sufficient for each coil, and the maximum current is 250 ampères. The bobbins on which the fixed coils are wound, and the sole plate of the instrument, are made of good insulating slate, and the beam of the balance is cut at each end, so as to avoid Foucault currents in the frame work and sole plate.

To prevent excessive shake during the use of the instrument, and for convenience of portability, capstan headed stop screws L are attached to the supports at the ends of the fixed scale M, and to an upright at the middle of the

Digitized by Google

suspension trunnion. In the ordinary use of the balance these stop screws are turned until they are just clear enough of the movable scale N (which forms the front bar of the beam) and of the trunnion, to allow the beam to swing freely. For packing, the trunnion screws are turned back, the beam lifted up against two stops above the trunnion, and two packing pieces containing V's for the trunnion slipped between them and fixed by the screws, while the screws at the end of the scale M are screwed so as to grip the movable scale. The instrument may then be carried about, or sent anywhere, with perfect safety under ordinary usage.

The method of using this balance is similar to that of the other balance, already fully described in these columns. The instrument having been levelled, and the stop screws adjusted so as to limit the shake, as above indicated, the proper weight is put on the carriage P, and the corresponding counterpoise weight in the trough Q, and the zero adjusted. Before making this adjustment the carriage and weight are moved to the zero of the movable scale by pulling the cords R S, which move the slider T. Having set the index of the carriage exactly to the zero line, using the lens which is supplied with the instrument, if necessary, the flag U should be turned by moving the handle V until the index W on the end of the scale points to the middle one of the five black lines on the vertical scale, when the beam is allowed to swing freely and come to rest. Should by any accident the flag not have sufficient power the mass y on the back bar of the beam may be slipped a little to one side, until the flag is able to make the adjustment. A second vertical scale Z is fixed at the left hand end of the beam, and the index A should point to the middle line of it when the index W points to the middle line of X. The two scales are placed in the instrument to allow the observer to see whether by any accident the ligament has been elongated since it left the maker's hands. Such an elongation of the ligament may take place with rough usage, and a slight change of constant would be the result; but it very rarely occurs. The mode of using the balance for the different classes of measurements will be more readily understood from the diagram Fig. 2. In this diagram B_1 represents a set of non-inductive resistances of suitable magnitude for the potential of the circuit to which the suspended coils are to be connected. Suppose, in the first place, that the balance is to be used as a voltmeter. The handle C_1 of the switch is turned to volt, and the electrodes D_1 E_1 connected to the points whose difference of potential is to be measured. The current then flows through the electrode E_1 and the suspended coils A B to the switch, then from the "volt" terminal through the fixed coils H I to the "watt" terminal, and from that terminal through the resistance B_1 to D_1. As the result of this current, the right hand end of the beam is deflected upwards, and the weight has to be pulled towards the right in order to restore the balance. The distance through which the weight has to be moved gives the couple produced by the ampèrian forces between the coils, and from the constant supplied with the instrument the potential between D_1 and E_1 is deduced. It will be seen that by this method of using the balance, small currents may be measured. It is, in fact, a modified "centiampère" balance. The maximum current these coils are expected to carry is 1 ampère, and currents from $\frac{1}{10}$ to 1 ampère may be measured in this way.

Next suppose the instrument is to be used as a wattmeter. The switch handle is turned to "watt," the electrodes D_1 E_1 connected to the supply mains, and the electrodes F_1 G_1 of the current coils J K connected to the two sides of a break in one of these mains. The whole current passing that break flows through the coils J K, and a current proportional to the difference of potential between the mains flows through the movable coils, but not through the fixed fine wire coils. The left hand coil of the movable system is thus acted upon by a force proportional to the product of the difference of potential between the mains and the current passing through them—that is, proportional to the rate of working in the circuit.

For the measurement of current the strength of which exceeds 1 ampère, the instrument is used heterostatically—that is to say, a constant measured current is passed through the suspended coils, and the current to be measured is passed through the fixed current coils. The connections for this use of the instrument are the same as for the measurement of watts. When a constant e.m.f. is available, the current passed through the suspended coils may be measured by the instrument itself, by first turning the switch to "volt," and adjusting an external resistance so as to obtain the required current, and then turning the switch to "watt," and at the same time increasing the external resistance by an amount equal to the resistance of the fixed coils H I. Generally, however, a separate indicator or galvanoscope requires to be used in circuit with the suspended coils of the balance when it is used for the measurement of ampères. This indicator can, of course, be standardised by the balance itself, arranged for the measurement of small currents, and it need not be capable of measuring change of current, but it should be sensitive to such change.

COMPOSITE ELECTRIC BALANCE.

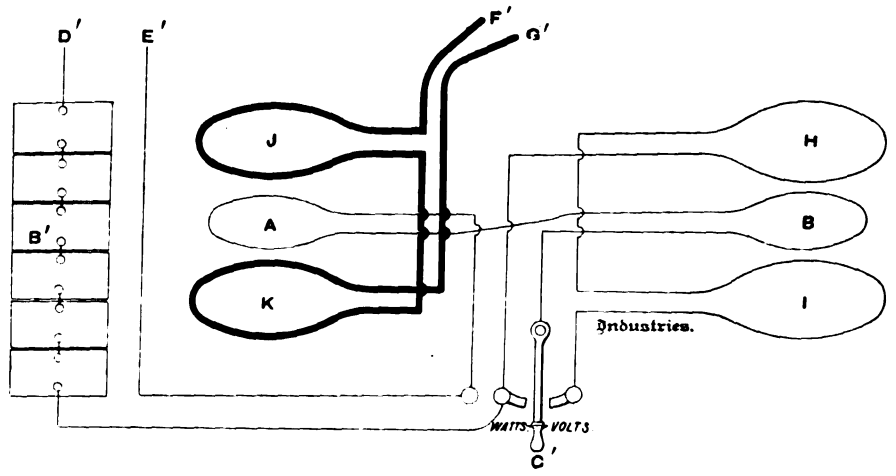

Fig. 2.

In standardising this balance two sets of weights are determined, one of which, generally marked $v\,w_1$, $v\,w_2$, $v\,w_3$, is used when the instrument is connected as a voltmeter or a centiampère metre. The current corresponding to any displacement of the weight is, in this case, half a centiampère, one centiampère, and two centiampères per division of the fixed scale for the three weights respectively. The other set is adjusted to measure the current flowing through the fixed coils J K when a quarter of an ampère is flowing through the suspended coils. There are two weights in this set, marked $w\,w_1$ and $w\,w_2$. The smallest weight has to be displaced one division of the movable, or equal division, scale for each tenth of an ampère flowing through the fixed coils J K, and the larger weight has to be displaced one division of the movable scale for each half of an ampère flowing through these coils.

This second set of weights also serve for the watt measurements, as all that requires to be known in order to allow the constant to be deduced is the resistance in the circuit of the suspended coils. Suppose this resistance to be equal to R, and the number of volts between the terminals to be V. Then the current through the suspended coil circuit $=V/R$, and the constant of the instrument requires to be divided by this quantity and multiplied by the number of ampères used when the constants were determined—that is, $\frac{1}{4}$ in this case. Hence the constant supplied with the instrument divided by $4\,V/R$ will serve in any particular case for the measurement of the current through the fixed coils or the circuit of the installation. Let for any particular measurement the reading on the scale of the beam be N divisions, and the constant supplied for the weight used be C, and we get for the current in the circuit:—

$$A = \frac{CRN}{4V}.$$

Now the number of watts being used in this circuit is equal to $A \times V$, that is to $CRN/4$, or the constant to be used for the calculation of watts is equal to the constant supplied for the measurement of ampères multiplied by $R/4$ where R is the total resistance in the circuit of the suspended coil.

In connection with the use of instruments of this class for the measurement of potentials, or of energy in alternating current circuits, the question of the effect of the self induction and the mutual induction of the coils of the instrument on its indications has always to be considered. Consider first the measurement of volts by the instrument just described. The suspended coils are about 4cm. mean radius; the diameter of the cross section is about 1·1cm., and they each contain on the average a little under 400 turns. The co-efficient of self induction of such a coil is approximately 18×10^6cm. The fixed coils have about the same mean diameter, and the section is square, 2cm. to the side, and they contain each about 670 turns. The co-efficient of self induction of this coil is about 36×10^6cm. The mutual induction between the movable and fixed coils is zero, as the fixed coils are at equal distances on opposite sides of the movable coil, and the one attracts while the other repels. There remains the mutual induction between the fixed coils, the mean distance between which is 5cm. This is of opposite sign to that of the self induction; but as it is small compared with it, and is favourable to the instrument, we may neglect it. Taking, then, the sum of the self inductions of the two movable and two fixed coils, we get for the induction co-efficient of the instrument 108×10^6. Let R be the total resistance of the circuit supposed, with the exception of the instrument, to be non-inductive; E the electromotive force at time t, and C the current flowing at that time; and L the co-efficient of induction. Then

$$RC = E - L\frac{dC}{dt}.$$

Assuming that $E = E_0 \sin \frac{\pi}{\tau} t$ where E_0 is the amplitude of the alternating e.m.f., and 2τ its period, we get

$$L\frac{dC}{dt} + RC - E_0 \sin \frac{\pi}{\tau} t = o \quad \ldots\ldots\ldots\ldots (1)$$

From this we deduce that

$$C^2 = \frac{1}{2} \frac{E_0^2}{R^2 + \pi^2 \frac{L^2}{\tau^2}}.$$

Now, since the force between the movable and the fixed coils is proportional to the square of the current, the readings for volts deduced from it will be proportional to $E_0/\sqrt{R^2 + \pi^2 L^2/\tau^2}$, and thus the indications of the instrument will be diminished, by induction, in the ratio of R to $\sqrt{R^2 + \pi^2 L^2/\tau^2}$. The resistance of the coils of the instrument is a little over 40 ohms, and the additional resistance is usually made equal to six times the number of ohms that there are volts to be measured. On a 100 volt circuit, alternating at the rate of two hundred reversals of the potential per second, we should have the ratio of the indicated potential to the true potential equal to $640 \times 10^9 / \sqrt{640^2 \times 10^{18} + 3{\cdot}1416^2 \times 108^2 \times 10^{12} \times 200^2}$ equal to 0·9945; that is to say, the indicated potential would be fully a half per cent. too low. The rate of alternation is here taken rather higher than the usual practice, and the induction co-efficient somewhat overestimated, so that we may conclude that for ordinary purposes such an instrument forms a reliable voltmeter. For measuring the number of volts in the supply mains of transformer circuits, the resistance R becomes so great that the indications for alternating and continuous e.m.f.'s are absolutely the same, so far as they can be measured.

For the measurement of watts, the induction co-efficient is the sum of the self induction of the two suspended coils, or, approximately, 36×10^6. The effect of mutual induction between the fixed or current coils and the suspended coils is zero, since they are symmetrically placed one above and the other below the suspended coil, and the current made to flow in opposite directions in the two. From equation (1) above we have by integration

$$C = Ae^{-\frac{R}{L}t} + \frac{E_0 \tau}{\sqrt{R^2\tau^2 + \pi^2 L^2}} \sin\left(\frac{\pi}{\tau} t - \varepsilon\right)$$

where $\sin \varepsilon = \frac{\pi L}{\sqrt{R^2\tau^2 + \pi^2 L^2}}$, and $\cos \varepsilon = \frac{R\tau}{\sqrt{R^2\tau^2 + \pi L^2}}$

This quantity ε gives the difference of phase between the current flowing through the coils and the e.m.f. on their terminals. Taking the same values for R and τ as before, we find

$$\sin \varepsilon = \frac{3{\cdot}1416 \times 36 \times 10^6}{\sqrt{620^2 \times 10^{18} \times {\cdot}005^2 + 3{\cdot}1416^2 \times 36^2 \times 10^{12}}} = {\cdot}000011$$

which gives ε equal to a little over two seconds of angle. It is therefore clear that if the e.m.f. is as much as 100 volts, the instruments will give to a very high degree of approximation the true watts, so long as the difference of phase between the current in the fixed coils and the e.m.f. on the supply mains does not approach 90° nearer than a few minutes of angle—that is, so long as there is any sensible amount of work being done in the circuit.

FOREIGN INDUSTRIES.

(From our own Correspondents.)

PARIS, 29TH MAY, 1888.

THE IRON MARKET.—Prices have again given way, and business is now being transacted at the rates which prevailed before the last circulars were issued by the merchants announcing a rise. This lamentable state of affairs is not due to a lack of orders, as business is brisk and increasing; but competition among the merchants has exceeded all reasonable limits. As if matters were not bad enough already, the merchants are selling to petty dealers, who in their turn sell to the consumer at a price below that asked by the manufacturers. We shall now see whether or not the latter are prepared to carry into effect their threat to establish a common sales office and to ignore the merchants altogether. From the reports received from the provinces it would appear that trade is somewhat less active this week, in consequence, probably, of the Whitsuntide holidays. Prices are firm, and manufacturers have plenty of work in hand. All the details of the combination between the manufacturers of the Nord and those of the Centre are now agreed to; the syndicate of axle makers, too, is definitively formed, and is to last two years. The foreign trade is not active. The temporary admissions of pig iron have greatly increased in anticipation of the restrictions which will shortly come into force, and amount to 41,383 tons in the first four months of the year, against 27,918 tons in 1887; but the duty-paid imports are only 8450 tons, against 13,027 tons. The total imports of finished iron amount to 8082 tons, against 11,863 tons, those of steel being 3245 tons, against 5502 tons. The exports of finished iron show a considerable increase, except in the case of rails, which have decreased considerably, leaving the total exports 11,582 tons, against 11,399 tons in the corresponding period of last year. The exports of steel amount to 5654 tons, against 15,792 tons in 1887. The shrinkage here is chiefly in rails. Steel plates have increased from 35 tons to 421 tons.

THE METAL MARKET.—The copper market preserves the same features which have distinguished it for several weeks past. The demand is light, stocks steadily increase, and prices, supported by the syndicate, remain firm. The drop in tin has brought consumers into the market. Business is brisk, and the downward course of prices is checked. Lead continues to decline. Prices have now fallen to the level at which they stood before the recent rise, and they will probably go lower yet. The demand is reviving for spelter.

SOPHISTICATED WINE.—The death of eleven persons in the South of France, traceable to arsenic in the wine sold by a local merchant, has directed attention to a new process of sophisticating wine. *Mouillage* has long been a custom in the trade. It consists in multiplying the quantity of a good wine in the following manner: A quantity of good wine is purchased, and to it is added an equal quantity of a much cheaper sort. Sometimes water is also added. This is the *mouillage*. The process does not, however, end here, for the eye and the palate of a fairly good judge, to say nothing of the analyst, would easily detect the fraud. The doctored wine is flat to the taste, and spoiled in colour. The palate of the taster and the skill of the analyst have now to be cheated. This is effected by adding alcohol. Sometimes the alcohol is added pure; sometimes it is introduced in the form of glucose from which alcohol is derived by fermentation. There remains the colour. Those who have travelled much in France may have noticed acres of tall flowers called hollyhocks, and wondered for what purpose they were grown. The petals of these flowers afford a decoction which is capable of restoring the colour to the wine without revealing its presence to the chemical analyst. This was the old and harmless method; but it appears that we have grown less scrupulous and less careful, for in the case of the wine which occasioned the deaths alluded to, it was found that coal tar colours had been substituted for the hollyhock petals. The matter is yet under investigation; but it is said that some arsenic was contained in the colouring agent.

BERLIN, 28TH MAY, 1888.

THE COAL MARKET.—The condition of the coal market in Upper Silesia at the present moment is not very satisfactory. At the commencement of the month the demand for domestic and gas coal considerably decreased, but this was partly compensated for by the increased requirements of brick and lime kilns. The cold weather, which returned, accompanied by frost, about a fortnight ago, had only a local and temporary effect, but did not influence the market. The collieries in the Eastern districts only have during the month done a fair export trade, whilst those in other districts have had to restrict their output in order to avoid the accumulation of stocks. The sales of coke have been satisfactory.

THE IRON MARKET.—The event of the week has been the proposal for an agreement between the German rolled iron syndicate and the Austro-Hungarian bar iron syndicate. The initiative has been taken by the latter, who offer to abstain from exporting any iron to Germany, provided the German syndicate undertakes not to send any more iron to Austria-Hungary, with the exception of building iron for further working up. Two large iron works, which have hitherto kept aloof from syndicates, have now agreed to adopt the prices of the rolled iron syndicate for Mid Germany, but without allowing their output to be regulated by the syndicate. The general condition of the market remains satisfactory. There is a fair demand for crude iron in the Upper Silesian districts at the same prices as in the previous week. Bars are now quoted at 140s. to 142s., angles and profile iron at 155s., and sheets at from 160s. to 165s. The difficulty between the Bromberg railway administration and the rolled iron syndicate, which I mentioned in my previous letter, has been overcome by the syndicate agreeing to a reduction in price of 3s. per ton, and the order for rails has consequently been placed with German steel works. The Hanoverian State railway invited tenders a short time ago for the supply of 1450 tons of steel rails, and the Georg-Marienhütte, in Osnabrück, obtained the contract at 116s. per ton at their works, their offer being the lowest which was made. Tenders received from English works were somewhat higher. The Königin-Marienhütte, in Cainsdorf, obtained a contract for 1216 tons of ingot iron sleepers, at 124s. per ton delivered at their works; whilst the Witten works were successful in obtaining an order for the supply of 250 tons of fish plates and 160 tons of switch tongues, at 118s. delivered at their works. At a recent meeting of the Union of West German Sheet Manufacturers it was stated that the works belonging to the union were well employed with orders at remunerative prices, and that a further advance in the price of boiler plates was justified on account of the high rates at present quoted for coal, coke, and pig iron. The condition of the small iron and hardware industry in the district of Hagen is very satisfactory, and the works have plenty of orders on hand for builders' fittings, agricultural implements, and tools.

LINEN.—The orders which have recently been received in Bielefeld for linen goods have not been very considerable; but notwithstanding this the manufactories have been well employed with old orders for bed and table linen. Business in linen underclothing is well developed, and factories are working full time. The demand for yarn by the Rhenish Westphalian spinning mills has not been particularly active; but the export trade has been satisfactory, in consequence of previous orders on hand, and the production has been disposed of.

SUGAR.—At the beginning of last week the sugar market was quiet, but towards the end of the week considerable orders were received from home refiners. In the Magdeburg market the sales during the week amounted to 3750 tons, whilst in that at Halle 11,000 bags of refined sugar changed hands. Offers are only being made in moderation, since refiners are well employed in the working up of raw sugar contracted for some time ago, and which has already been delivered. The process most in favour in Germany for the separation of molasses from sugar by the use of lime is that of Herr C. Steffen. The strontian process, on the other hand, is, in consequence of the high price of carbonate of strontium, now only used by those firms which have the necessary plant installed, and is not being adopted by other works.

VIENNA, 28TH MAY, 1888.

THE IRON MARKET.—With the exception of a reduction in the base price for black sheets, which Bohemian makers have found necessary, no change of importance has taken place in the iron trade, and even the reduction just mentioned has only local importance, and it is satisfactory to note that, to make up for it, the Alpine Mining Company have found it possible to increase their price for heavy sheets 16s. per ton, a step which is justified in their case by the great number of orders they have now in hand, and which will engage their capacity of production for several months. Consequently, the works are not able to accept orders even at the increased price for immediate delivery. In bar iron, the market is fairly satisfactory, and has, moreover, received a considerable impetus by the agreement of the Austrian bar iron syndicate with their German rivals, under which Austrian makers will regain the profitable Galician market which during the last year or so they have seen slipping through their hands owing to the competition of Upper Silesian manufacturers. Under the new agreement, Roumania, which at present has no commercial treaty with Austria, would be left entirely to the German manufacturers, whilst Servia and Galicia are to be supplied jointly by German and Austrian makers. The agreement has yet to be ratified by the local syndicates, but Austrian iron masters are somewhat sceptical regarding the question whether their German rivals will carry out these stipulations when they find that by doing so they will lose a large portion of their Galician trade. In Hungary, business in all branches of the iron trade is fairly satisfactory, although prices are not advancing, except in the case of heavy sheets, for which there is momentarily a strong demand for shipbuilding purposes. Castings, and especially cast iron stoves and ranges, are in good request, dealers already beginning to place their orders for the autumn trade. The demand for rails is brisk, and prices are firm.

TEXTILES.—Owing to the favourable season, business in most branches of the textile industry is very brisk. There is a strong demand for satins, cretonnes, and Warnsdorfer cottons, and unbleached cotton piece goods are also in good request. In cloth and woollen goods the market is somewhat languid, and only those makers do a fair trade who succeed in imitating English patterns. Business in silk goods, velvets, and ribbons is satisfactory.

SUGAR.—The season is now practically ended. The total quantity of beetroot declared by the sugar factories to the Excise amounted to 3,310,000 tons, as compared with 4,290,000 tons in the previous year, and 2,650,000 tons in the season 1885-86. The total exports during the past season amounted to 20,000 tons raw sugar and 99,000 tons refined sugar, together equivalent to 130,000 tons of raw sugar, as compared with 200,000 tons during the previous season. The total payments for Excise duty exceeded 26 millions of florins, whilst nearly 14 millions have been returned to the makers in the shape of export bounties.

A NEW CIGARETTE MACHINE.—Messrs. Jadowsky and Schmitt of this town have, after a long series of trials, perfected a machine for the manufacture of cigarettes, which is remarkable for its ingenuity and workmanship. The frame of the machine consists of a cast iron table supported on angle iron legs, and the various organs of the mechanism are geared to a main spindle, which receives motion either from a hand crank or by power from a belt. At each revolution of the spindle a complete cigarette with cardboard mouthpiece is turned out. The tobacco, slightly moistened, is placed in an open trough, the bottom of which is in part formed by an endless cotton band travelling forward under a knife, which automatically cuts off the quantity of tobacco required for one cigarette. This quantity is then pressed into a cylindrical form between a pair of semi-circular metal sleeves, and retained in this mould until a little piston pushes it into the paper envelope, which has meantime been prepared by another part of the machine. The tissue paper and the tape of cardboard for the mouthpiece are on separate rollers under the table, and the former is drawn between guide rollers under a printing roller, which prints the brand on to the paper. The paper band is then seized by a gripper, whilst a knife cuts off the length required to go round the cigarette, leaving sufficient length for the lap, which is gummed by being pressed against a roller. The piece of paper is next coiled over a mandrel, and then released from the gripper, which moves back to seize again the end of the paper tape, whilst the paper cylinder is pushed into a metal tube. Meanwhile, the cardboard tape has undergone a similar operation, and a little cylinder of cardboard is pushed into the tube from the other end, where, through its own elastic expansion, it jambs itself tight in the tube of tissue paper. This receives now its charge of tobacco from the mould already mentioned, and the finished cigarette is thrown on to a travelling band, which deposits it in a box at the side of the table. An almost similar machine, by the same inventor, was shown at the Manchester Exhibition last year, and illustrated in *Industries*, Vol. III., page 463.

BRUSSELS, 29TH MAY, 1888.

THE COAL MARKET.—The coal market continues firm, and there is especially a good demand for nuts. The rates for coke and coke dust are also maintained. The Longwy works have bought 90,000 tons of coke in Westphalia, their offer of 11s. 3d. per ton not having been accepted by Belgian producers. The balance sheet of the united collieries of Bonne Espérance, at Montigny-sur-Sambre, and at Du Bois Communal, shows a net profit of £3,006, on a capital of £72,000. A contract has been made for 2000 tons of coal for the State railways, and further contracts will be made to-morrow on the Brussels exchange for the supply of coal and briquettes required during the second half of the year for the Ostende mail steamers. These contracts will be for two lots each of from 9000 to 10,000 tons. A number of coal contracts will terminate in a few weeks, and it is expected that the new contracts will be made at current rates without any further rise.

THE METAL MARKET.—The constant production of the four blast furnaces which have lately been blown in, as mentioned in previous letters, is beginning to tell on the market, and stocks are now commencing to accumulate. The rates for pig iron, which had risen to 56s., have dropped to 52s., on account of the large imports from Holland, and the small exports to America. There is consequently greater ease, and those rolling mills which have no blast furnaces of their own find themselves in a better position. Efforts are at present being made to obtain an American order for 20,000 tons of girders. The merchant iron syndicate is maintaining the rise of 4s. per ton, and the following are the present rates, with a discount of about 8s. per ton for home consumption, and of 6s. for export:—

Merchant Iron.

No.	Delivered at a Belgian Railway Station.	For Export.
1	96s.	92s.
2	104s.	98s.
3	112s.	104s.
4	128s.	116s.
5	144s.	132s.

Angle Iron.

2	104s.	100s.
3	112s.	106s.
4	128s.	118s.

No. 2 sheets are quoted at 120s.; steel sheets, at 140s.; large plates, at 112s.; and girders, at 100s. For the contracts for the Goliath rails, to which I referred last week, the Government will accept the offer of the Acieries de France to supply 2000 tons at 87s. 7d. per ton, the rest of the order being divided between the Cockerill Company, the Ougrée Company, and the Angleur works.

THE EXHIBITION.—The English section of the Exhibition is proving very attractive to visitors. Among the exhibits

Digitized by Google

are cutlery, pottery, textiles, weaving machinery, life saving apparatus, and a type setting and distributing machine. In connection with the English section there is a Japanese village. Next to the English portion of the Exhibition the German section is making most progress under the direction of M. Cornéli, the German commissioner-general. The Austrian and Italian sections are next best advanced, whilst the Belgian and French portions are in the most backward condition. In the machinery department, however, rapid progress is now being made. Two of the large engines for driving the machinery are nearly ready, and a third is now being erected. The shafting for the electrical machinery is now in its place. The foundations for the dynamos are also finished, and the circuits are now being laid, and lamps are being fixed. The electric light installation for the Paris hippodrome, which began performances last week, consists of thirty-five Brush lamps.

Electric Lighting.—The Thomson-Houston Company are actively pushing the electric light in Belgium. They now propose to light the Galerie du Roy in the Passage St. Hubert. They have also been commissioned to light one of the largest spinning mills in Ghent. Messrs. Mourlon & Co. are paying special attention to private house lighting, for which purpose they are introducing a new American petroleum engine, which is of simple design and very steady in its running. Experiments made with it at the works of the firm proved very satisfactory, and it is now used in several installations of fifteen to fifty lamps. The Comte de Flandre, the brother of the King, is having the electric light installed in his palace in the Place Royale, Julien accumulators being used; and Messrs. Mourlon are supplying plans for a large installation at Laeken for the King's palace.

DÜSSELDORF, 28th May, 1888.

The Iron Market.—The iron market has wholly recovered from the slight relapse which took place in April. The renewed life visible in the trade in crude iron is doubtless due, in part at least, to the constantly advancing prices for coke. Coke makers seem disposed to push their advantage to the utmost limit, but the wisdom of this policy is questionable. Consumers seem to have satisfied their most pressing needs for basic steel pig, for the demand has slackened a little. For other classes of pig the market remains unchanged since my last report. Production steadily increases, and larger quantities are being imported from England. The production of pig iron in the German Empire reached in the month of April 349,880 tons, against 314,621 tons in the corresponding month of last year. This quantity consisted of 180,615 tons of forge and spiegel pig, 98,293 tons of basic steel pig, 28,094 tons of Bessemer pig, and 42,878 tons of foundry pig. The total output of pig iron in the first four months of the current year amounts to 1,395,455 tons, against 1,200,439 tons in the corresponding period of 1887—an increase of 16·25 per cent. The finished iron market is not satisfactory in all its features. Business is very animated in common plates, and there is considerable activity in joists; but bars are dull, and there is no improvement in wire. It must be admitted that the prospect in these directions is not encouraging. Business is restricted by high prices, and the tendency of the raw materials is to advance still further. Sheets are a little more sought after. The international rail market is in a bad state. For the Copenhagen contract for 2000 tons gained by an English firm, one German firm tendered a price which would not exceed £3. 14s. at works, a quotation which is much below the cost of manufacture.

Higher Prices for Paper.—A meeting of paper makers has been held at Hamm, at which it was agreed to raise the prices of straw paper and coloured and grey packing paper throughout Westphalia, Rhineland, Saxony, and the South German States. Another meeting is to be held on the 4th of June, to fix the prices for the second half of the current year. The exports of these classes of paper in the first two months of the year amounted to 49,210cwt., against 40,728cwt. in the corresponding period of 1887.

LILLE, 29th May, 1888.

Textile Manufactures.—Though the general situation has not materially changed since my last report, symptoms of improvement have appeared in some branches of the trade in textile goods. In linen fabrics, the tendency of the market is towards languor, as is usual at this season of the year, and the volume of business compares unfavourably with that of the corresponding period of last year; but more encouraging accounts have come to hand from the Roubaix-Tourcoing district. The business in woollen goods has become a little more active. Important orders have been booked within the last ten days, and manufacturers seem disposed to regard the revival as indicative of approaching activity. Such hopes, however, have been disappointed so often, that it would be rash to predict anything concerning this matter. South American wool constitutes a fairly active market, and prices have an upward tendency. Australian is for the moment neglected, but there is a prospect of greater animation and higher prices in this market. There is nothing new to record of the cotton or silk trade. The declared values of the textile fabrics imported and exported in the first four months of the current year are as follow, the figures within parentheses being the values for the corresponding period of 1887. Imports: Linen goods, £74,640 (£75,280); jute goods, £20,720 (£22,920); cotton goods, £697,600 (£830,640); woollen goods, £711,120 (£740,440); and silk goods, £806,720 (£696,560). Exports: Linen goods, £122,440 (£108,160); jute goods, £31,080 (£31,600); cotton goods, £1,486,160 (£1,632,800); woollen goods, £5,069,120 (£4,582,040); and silk goods, £3,172,120 (£3,248,920).

Flax and Yarn Market.—The market for home grown flax is wholly lifeless, the quantity remaining in the hands of sellers being now very small. The few transactions which have taken place show prices to be in favour of sellers, a circumstance largely due to the cold weather, which threatens to injure the growing crop seriously. The market is a little more active for yarns, both linen and jute yarns being more sought after.

The Iron Market.—The amount of business in iron is undiminished. Fresh orders come to hand freely, and as manufacturers are already provided with sufficient work for at least several weeks to come, the tone of affairs is cheerful. Manufacturers have confidence in the situation, and contemplate the near future in a hopeful frame of mind. It is scarcely necessary to add that prices remain very firm. The steel works at Isbergues have won a success in Belgium. The State Railways Administration asked for tenders for 8000 tons of steel "Goliath" rails, that is the 52 kilogram (114·4 lb.) per mètre rails. The Isbergues Company tendered for 2000 tons, £4. 7s. 7d. delivered at Schaerbeck, the lowest price offered.

The Sugar Industry.—It is now officially stated that the quantity of beet operated upon in the season now practically ended was 3,614,632 tons, against 4,876,850 tons last year. Expressed in raw sugar, the production amounts, in round numbers, to 389,000 tons, against 480,000 tons in the previous season, a difference of 91,000 tons.

AMSTERDAM, 29th May, 1888.

Shipbuilding.—The new mail steamer "Bromo," built for the Rotterdam Lloyd Company, and intended for their fortnightly service between Holland and Java, has left the stocks at the yard of the Royal Shipbuilding Company Schelde, at Flushing. She is the largest vessel of this class yet constructed in Holland. The trial trip to the mouth of the Maas showed great steadiness and a speed of eighteen knots an hour.

Holland and the Transvaal.—Some more engineers for the Dutch Transvaal Railway have left for the Cape. After their arrival in the Transvaal, the total number of Dutch engineers engaged upon the railway there will exceed twenty. As the capital for building the line is guaranteed by the Pretoria Government, it is satisfactory to learn that the resources of the republic continue to expand in a remarkable manner, the receipts showing an increase of nearly £80,000 for the first quarter of 1888.

Coffee.—Recent advices from Batavia show that the production of coffee in Menado, a well known coffee district, is again increasing rapidly. It rose to 22,000 piculs in 1885, and to 28,000 piculs in 1886, but suddenly fell to 4000 piculs last year, owing to the failure of crops. This year's production is estimated at 15,000 piculs. This coffee is of the very highest quality, and commands a corresponding price.

MADRID, 28th May, 1888.

Basic Steel.—At the iron works of Messrs. Duro & Co., of Telguera, Martin-Siemens steel is made by the acid process; but it is found expensive to import Bilbao ore into Asturias, when phosphoric ore can be obtained more cheaply in the district. The firm is consequently preparing to work the basic process, but it will be some time before they can induce the naval authorities to sanction this kind of steel for shipbuilding purposes, as it has hitherto been totally excluded fron the national arsenals and yards.

The Alkali Industry.—The recently disclosed invention of Mr. Chance, of Birmingham, relating to the recovery of sulphur from alkali waste in the manufacture of soda, is likely to give rise to the manufacture of soda in Spain by utilising the sodium sulphate mines in the province of Madrid. So far, these have only been worked on a small scale, and merely for sulphate of soda for glass works, but none has been converted into carbonate of soda. There is no likelihood, however, of any soda being manufactured for export, and the most that can be expected is a supply sufficient for a part of the home demand.

Cotton Mills.—The cotton mills belonging to the old established company, La España Industrial, which are probably the largest in Spain, are to be fitted throughout with new machinery. At the meeting of shareholders at which this decision was come to there was some opposition to this proposal of the directors, but the resolution was ultimately carried by 529 votes against 177.

NEW YORK, 19th May, 1888.

The Coal Market.—The improvement in the anthracite coal trade which I reported in my last letter continues, and though it is not possible to prevent cutting of prices by individual operators anxious to move their stocks and keep up production, prices are generally well maintained. The opening of navigation on the lakes is bringing a fair demand from the West, stocks at lake ports being thereby reduced.

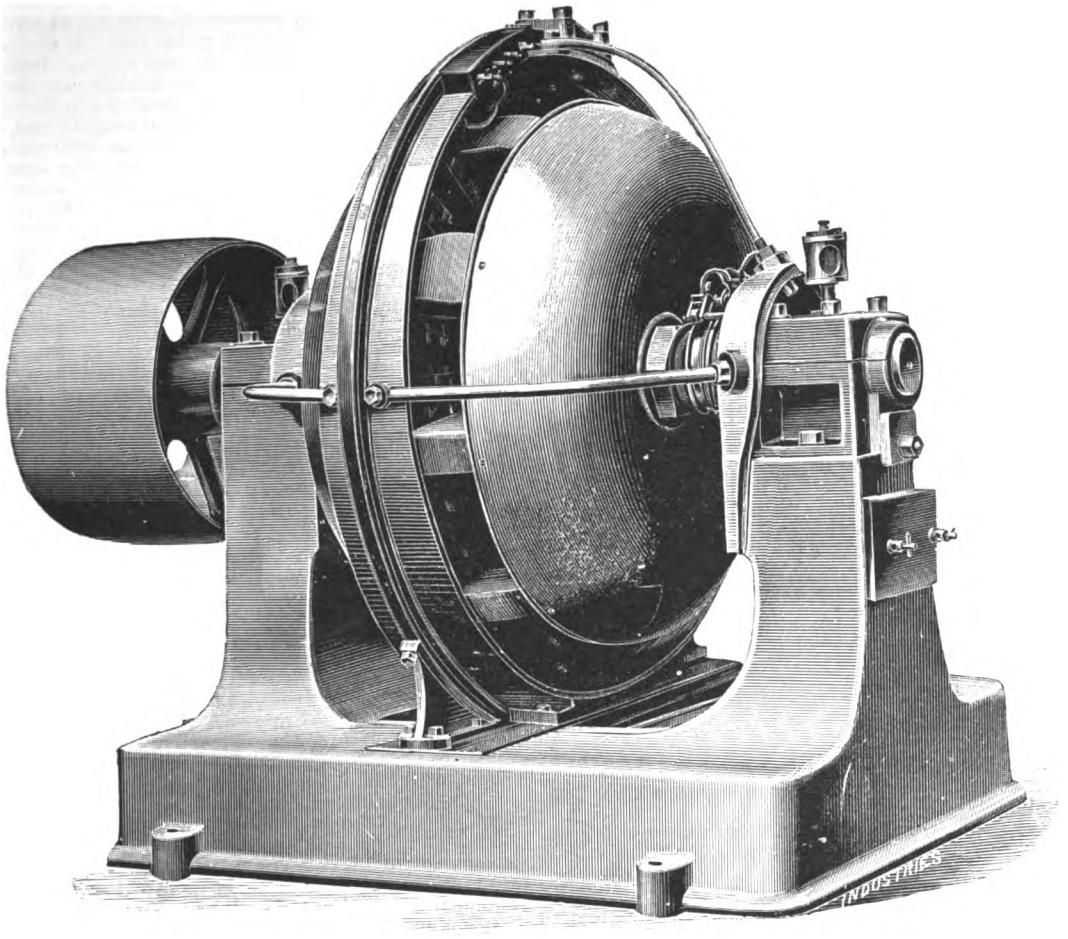
The Iron Market.—Prices here have been gradually dropping, but without leading to much business; and although there is nothing on which to base predictions of early improvement, the chances are that the decrease in consumption has almost reached its limit. The shrinkage has been at the rate of 1,250,000 tons per annum, as compared with 1887, and while business is still large, as against that in the periods before 1884, the loss of so much business, compared with the large production of the last two years, is a serious matter. The shrinkage in prices is the most serious point, as it represents a decided cutting down of both wages and profit; buyers in the meantime are acting with great caution, and buy only small quantities at a time. The pig iron market has been an irregular one, but on the whole decidedly easier. Prices are not entirely settled; makers of some brands have fixed their ideas on certain figures as a minimum, while others are undecided as to what to do. It is safe to say that prices will go very low, perhaps as low as they have ever been, before any reaction takes place. Reductions are being fought step by step, but there are the same reasons why prices should become as low as at previous periods of depression, and the additional one of Southern competition. Business in manufactured iron has not improved. In some departments there has been a little more inquiry, but offers were at such low figures that only moderate amounts were bought. Mills which are running close to the end of their orders are taking a few hundred tons at about cost price, but only very small lots can be sold with a fair margin of profit. In plates and shaped iron there is no improvement whatever, and while manufacturers think they see business in the near future, very little has been placed during the last month. Prices are weak and irregular, but the general quotations are: 1·8c. to 1·85c. per lb. for bars; 1·9c. to 2c. for plates; and 2·10c. to 2·15c. for angles.

The Metal Market.—The copper market has shown greater activity than for some time past, and prices have slightly risen in consequence. Lake navigation has opened, and the first cargo of copper has been shipped. The belief among consumers has been freely expressed that the break in tin was the first sign of weakening in the copper syndicate, but transactions on the metal exchange give no hope for better prices at present. The tin market is still very much unsettled. A week ago a 10-ton lot sold on the exchange at 20·30c. per lb., but all sales since that time have been at 18c. Plates are a little more active. Lead is very quiet, with but little business doing even at 4¼c. per lb. Spelter is quiet, with the market at 4·62½c. to 4·65c. per lb. for domestic.

Heating Railway Carriages.—The New York Railroad Club recently sent out circulars to obtain expressions of opinion from railroad officials on various points relating to steam heating, such as the use of flexible or metallic connections, the use of traps, the desirability of further delay before adopting a uniform coupler, and the coupler preferred. The lessons taught in the adoption of car couplers have impressed railroad men with the necessity of the early adoption of some uniform system of coupling the tubes. The answers received were not numerous, and were about evenly divided upon most of the points dealt with. The majority of the companies answering recommended one coupler.

PHILADELPHIA, 19th May, 1888.

The Iron and Steel Market.—Prices for Pennsylvania iron range from $19 to $20 per ton for No. 1 foundry, $18 to $18·50 for No. 2, and $16 to $16·50 for grey forge. Southern irons now seem to be out of the race, as there is no inducement to take them at present prices, which are but 50c. per ton less than local irons of the same grade. The steel rail market is very dull, and although $31·50 to $32 at mill is quoted in Eastern Pennsylvania, it is impossible to secure any but small orders. One of the Southern roads is said to have bought 12,000 tons from an Eastern mill, and an order for 20,000 tons was taken by the Chicago mills for Kentucky delivery. Apart from these sales only small sales are reported at the figures quoted.



The Oil Trade.—The investigation of the House Committee on Manufactures has brought out some interesting facts in connection with the monopoly of the Standard Oil Company. From the testimony of the late President of the Pennsylvania Railroad, that company in 1878 allowed the Standard Oil Company a rebate of 50 cents per barrel on all crude oil shipped by them, and in addition paid them 22½ cents on all oil shipped by other parties. The laying of pipe lines rendered them independent of the railroads, and since that time they have dictated their own terms. The total amount of rebates is estimated at over £20,000,000.

Tube Works.—The last of the eight large welding furnaces of the lap welding department of the National Tube Works, at McKeesport, Pennsylvania, has been put into operation. There is another furnace at the works, which is being fitted for electric welding. The capacity of the works has more than doubled in the last year, having increased from 40 tons per twenty-four hours to 85 tons. The Pittsburgh Tube Company's works, which were closed because of the refusal of the workmen to accept a 10 per cent. reduction in wages, has been again started, as the men have agreed to submit to a 5 per cent. decrease.

The Brotherhood Engine.—The Chester Foundry and Machine Company, of Chester, Pennsylvania, have secured the exclusive right to manufacture the well known three-cylinder Brotherhood engine, and have just finished fitting up a department with special tools for the work. The department will be under the charge of a superintendent from the English works, and the engines will be fully up to the English standard.

THE MORDEY ALTERNATOR.

THE MORDEY ALTERNATOR.

Some few years ago the manufacturers of continuous current dynamos vied with each other to produce new types, the motive being not so much a desire for improvement as for some distinctive design which would have the same commercial value as a trade mark. The number of different types which were thus brought on the market was considerable; but eventually the trade settled down to a few leading designs, which are now used with little variation by the best makers. The same process of evolution, which resulted in the survival of the fittest dynamo types for the production of continuous currents, seems now to be going on in regard to alternate current dynamos, and new designs are continually being brought forward. The latest example of this process of development is an alternator, designed by Mr. W. M. Mordey, and built by the Anglo-American Brush Corporation, in which a principle has been adopted which is decidedly novel in the construction of alternating current machinery, viz., the principle of an iron clad field. In continuous current dynamos the principle of an iron clad field, that is of such a configuration of the magnetic circuit as to produce no stray lines outside the machine, dates back to 1882, when it was first adopted by Wenström for a two-pole machine. In 1885 the same inventor employed it for a six-pole machine. In this case the system of field magnets surrounded the armature, and was arranged in the shape of a double shell, the inner web forming one pole and the two outer flanges the other pole, to which were alternately attached the north and south pole shoes. The magnetism was produced by two exciting coils laid into the shell between the central web and the external flanges. This type of iron clad field differs, however, from that adopted by Mr. Mordey in two essential points. In the first place, Wenström's exciting coils had a larger diameter than the armature, being arranged outside of it; and in the second place, the magnetisation of neighbouring pole shoes was of opposite character. In the machine shown above and on page 546, the exciting coils have a smaller diameter than the armature, and are wholly within it; and all the poles on one side of the armature are north, whilst all the poles on the other side are south. Thus the lines of magnetic induction flow through the armature in a direction parallel to the spindle on which the field magnets are mounted, and there is never a reversal of flow, as in other types of alternators. With a given strength of field and given speed, the e.m.f. created in the armature is, therefore, only half of what it would be were north and south poles of the same strength to succeed each other alternately. On the other hand, Mr. Mordey's arrangement has the great advantage of almost entirely avoiding magnetic leakage and economising exciting wire.

The construction of the machine will be readily seen from the illustrations given above and on page 546. The field system is built up of a central cylinder of wrought iron, forming the core, through the axis of which passes the spindle. This cylinder is surrounded by a single coil of exciting wire, the ends of which are brought out to two gun metal collectors which are insulated from the spindle. The exciting current is supplied by means of two brushes rubbing against these collecting rings. It is, however, not necessary to employ brush contacts at all. The exciting coil can be held stationary whilst the core revolves within, and the polar extensions revolve outside of it. In this case the exciting wire is brought down to the coil through a clearance left between two adjacent armature coils, and the armature would serve to support the exciting coil by means of the angle ring which is shown in our illustration, although in the machines as actually constructed, this ring is omitted, and the exciting coil revolves with the field magnets. As already mentioned, the core of this system of magnets is formed by a stout wrought iron cylinder. To the ends of this cylinder are pressed cast iron flanges, with radial extensions curving over the exciting coil. There are nine such arms to each flange, and they are so set as to bring the end faces of one set of arms exactly opposite those of the other set, with a clearance of $\frac{11}{16}$in. between them. The lines of force created by the exciting coil flow through the arms and leap across this narrow air gap, whilst the space between succeeding pairs of arms remains absolutely free from lines. The armature consists of eighteen coils of insulated copper strip, $\frac{7}{16}$in. wide. Each coil is supported on a porcelain core, $\frac{7}{16}$in. thick, and attached to a gun metal ring which, for convenience of manufacture and repair, is made in halves, the two portions being held together at the bottom by the attachment to the bed plate, and at the top by a special casting, clearly shown in our illustration. The two ends of each armature coil are brought out through porcelain insulators, and adjacent coils are joined in series by connecting wires, which are easily accessible. A separate armature coil is shown in our illustration by the side of the armature as it appears when built up. The edges of the porcelain cores are provided with notches through which the taping of the coils passes. This armature is placed within the narrow slot left between the polar extensions of the magnets, and as the latter revolve, the bundle of lines of magnetic induction flowing across each pair of pole faces is swept past the radial parts of the copper strip forming the armature coils, and thereby is created within these strips an e.m.f. which is proportional to the intensity of the field, the length of conductor acted upon, the linear speed, and the number of convolutions in each coil. It will be evident that there must be twice as many armature coils as there are pairs of magnet poles in order to avoid a differential action, and the circumferential dimension of the poles is equal to the corresponding dimension of the porcelain cores. As this machine is intended to produce a high e.m.f., all the coils in the armature have, as has already

been stated, been coupled in series; but it is obvious that any other combination can be adopted if a lower e.m.f. and more current be required. The machine is designed for an output of $17\frac{1}{2}$ ampères at 2000 volts pressure when running at 650 revolutions per minute. The accompanying diagram shows the characteristic when the speed and exciting power are kept constant whilst the current through the armature is varied. It will be seen that the difference in the terminal pressure between open circuit and full current is only 100 volts, and to produce constant terminal pressure a slight variation in the strength of the exciting current is all that is required. The total weight of the machine is 41cwt., of which 22cwt. is made up of the armature and field magnets. The external diameter of the field magnet castings is 2ft. 11in. To prevent loss of power from air resistance and to avoid noise, the field magnets are partly covered in by copper dishes. Two of these alternators are now being erected at the Oxford-street Electric Lighting Station (Messrs. Pritchett & Co.), to be used in conjunction with Mordey transformers also supplied by the Brush Corporation.

THE NEW AMERICAN FIELD GUN.

Captain C. W. Whipple, in the first number of a new publication—*The Journal of the United States Cavalry Association*—gives an interesting description of the new field piece which will shortly be issued to the United States artillery. In comparing it with the field guns of other nations, he draws some pardonable but rather incorrect conclusions, and claims for it that, with a less weight of metal, it has a higher muzzle velocity than any other gun of the kind, and that the Russian 15-pounder alone throws a heavier shell. Without going into the errors of such comparisons, we may say that the English gun he selects to compare it with is the 9-pounder R.M.L.

	English 12-pounder R.L. Gun.	American 3·2in. Rifle.
Calibre ...	3in.	3·2in.
Weight of gun ...	784lb.	791lb.
Length ...	92·35in.	83·2in.
Chamber ...	Cylindrical, 11·2in. long by 3·625in. in diameter	Ellipsoidal, 10in. long.
Rifling ...	Increasing twist from 1 turn in 120 calibres at breech to 1 in 28 at 35·8 inches from breech; thence uniform 1 in 28 to muzzle	Uniform 1 turn in 30 calibres.
Weight of projectile	12·5lb.	13lb.
Weight of charge ...	4lb. selected pebble	3½ to 3¾lb.
Muzzle velocity.	1686–1740f.s.	1710–1730f.s.

When this gun was introduced, about eighteen years ago, it was as good a gun as Europe could show; but very

Digitized by Google

soon after, all the Great Powers re-armed their field artillery, and for some time we were in the unenviable position of having a heavier equipment and a weaker gun than any of our neighbours; but it will be seen from the accompanying table that our present gun, the 12-pounder B.L., can well bear comparison with this its latest rival. The American gun consists of a steel tube containing the bore and the seat for the gas check; over the rear of the tube a jacket is shrunk, which projects 5ft. 6in. to the rear; there is a trunnion ring, sleeve, key ring, and base ring, which screws into the rear part of the jacket, and forms the seat for the breech block. The breech block is fastened to the body of the gun by an interrupted screw, which can be locked and unlocked into corresponding threads in the base ring by a lever handle, and the general arrangements for opening and closing the breech are similar to those in use in England.

In America, as elsewhere, great difficulty was found in obtaining a suitable carriage. A design has at last been obtained with cheeks of double steel plate, riveted together with curved flanges, above and below. The axle is of steel, braced by rods to the cheeks, and reinforced by two steel plates, $\frac{7}{8}$in. thick, projecting front and rear, and riveted together, thus giving the structure of a beam, with its depth in the direction of the greatest strain. The English axle tree, it will be remembered, is a steel forging, connected to the brackets by strong tensile stays, fitted at the centre with a spiral spring in a box, to give additional elasticity. The American brake, which is attached at each side, consists of two rods, one connected by an eye to the axle tree shoulder at one end, and at the other screwed into a hausing, which encloses a stout spiral spring. Through the latter passes one extremity of the second rod, which terminates in a nut that bears against the spring, its other end being fitted with a shoe that can be placed against the tyre of the wheel. This brake is found to act well; it can be attached or not at pleasure, and on the march acts as a mud scraper. In England we employ self acting friction brakes, applied to the naves, and also a hand brake that can be thrown in or out of gear. The weight of the American carriage is 1300lb., that of the English 1260lb.

SHIPBUILDING NOTES.

On the 19th ult., the steam tug "Hereward" went on her trial trip at Hull. The vessel was built by Messrs. Cook, Welten, & Gemmell, for Mr. C. D. Holmes, who was entrusted with the contract from the owners, Messrs. T. Gray & Co. She is the most powerful tug on the Humber, having triple expansion engines of 50 n.h.p., which are capable of making twelve miles an hour at 120 revolutions a minute. Steam is supplied from a steel boiler at a pressure of 150lb.

On Thursday, the 24th ult., Messrs. Robert Thompson and Sons, Sunderland, successfully launched from their yard a large steel screw steamer, named the "Drumburlie," built to the order of Messrs. Gillison & Chadwick, of Liverpool. Her dimensions are: Length, 305ft.; breadth, 39ft. 6in.; depth of hold, 25ft.; and has a deadweight capacity of 1830 tons. The vessel is classed 100 A1 at Lloyd's. The engines, which will be supplied by the North-Eastern Marine Engineering Company, Limited, of Sunderland, are of large size, having cylinders 23½in., 38in., and 62in. diam., with a stroke of 42in. There are two boilers of the cylindrical multitubular type, 11ft. 9in. diam. by 15ft. 6in. long. The vessel and her machinery have been built from the plans and specifications of Messrs. Flannery and Blakiston, consulting engineers, of Liverpool, who have also superintended their construction.

On the 26th ult., the Blyth Shipbuilding Company, Limited, launched a screw steamer, named the "Sultana," from their yard on the Tyne. The vessel has been built to the order of Messrs. Bailey & Leetham, of the Humber Iron Works, Hull, under the superintendence of Mr. Thomas Thompson, the owners' managing engineer. The principal dimensions are: Length, 265ft.; beam, 36ft.; and depth, 23ft. She is built on the three-deck principle, and the main and upper decks are of iron. There are six compartments formed by iron bulkheads extending from the keel to the upper deck. Four steam winches will be fitted for working the cargo; Amos & Smith's steam steering gear is on the bridge, and Emmerson & Walker's patent windlass on the forecastle deck. Triple expansion engines, with cylinders 23in., 36in., and 60in. in diameter, are being made by the owners.

A saloon paddle steamer, the "Princess of Wales," has been launched by Messrs. Barclay, Curle, & Co., from their yard at Whiteinch. The "Princess of Wales" has been built to the order of the Southampton, Isle of Wight, and South of England Steam Packet Company, and is intended for passenger service on the Southampton, Portsmouth, and Isle of Wight route. The dimensions of the vessel are: Length, 215ft.; breadth, 21ft.; and depth, 8½ft. The engines will also be built by Messrs. Barclay, Curle, and Co.

On the 26th ult., Messrs. Thomas Turnbull & Son launched from their shipbuilding premises, Whitehall, Whitby, a well modelled screw steamer. The new vessel is constructed of steel, and as she left the ways she was christened the "Northgate." Her dimensions are as follow: Length over all, 298ft. 9in.; length between perpendiculars, 288ft.; breadth, 38ft. 2in.; depth to top of floor plate, 20ft. 11in. She is classed A1 at Lloyd's, and her deadweight carrying capacity is estimated at 3440 tons. Her engines are of 175 n.h.p., and are constructed by Messrs. Blair & Co., Stockton-on-Tees. The new steamer has been built to the order of Messrs. Turnbull, Scott, & Co., London.

Messrs. Osbourne, Graham, & Co. launched from their yard at Hylton, on the 26th ult., a steel screw steamer called "Kathleen," which they have sold to Messrs. Pyman, Bell, & Co., of Newcastle. The vessel will take the highest class at Lloyd's, and has been built to carry a large cargo on a light draught of water. Her dimensions are 258ft. between perpendiculars, by 37ft. beam, and 16·95ft. to top of water ballast tanks, which are constructed on the cellular system fore and aft. She is built with short, full poop aft, raised quarter deck to bridge and long bridge, and topgallant forecastle, and is provided with four steam winches, a donkey boiler by Messrs. Welford Brothers, steam steering gear by Amos & Smith, of Hull, Harfield's patent windlass, and usual appliances for rapid loading and discharging. The engines will be fitted by Mr. George Clark, of Southwick, the cylinders being 20in., 33in., and 54in., by 36in. stroke, being of 160 n.h.p. The steamer will carry nearly 2500 tons on 17ft. 6in. draught, and steam nine to ten knots loaded.

Notices of Meetings.

NEXT WEEK.

SOCIETY OF ENGINEERS.—Monday, 4th June, 7·30 p.m. Paper to be read on "The Acton Main Drainage Works," by Mr. C. Nicholson Lailey.

ROYAL INSTITUTION OF GREAT BRITAIN.—Monday, 4th June, 5 p.m. General monthly meeting.—Tuesday, 5th June. Lecture on "Conventions and Conventionality in Art," by Mr. Sidney Colvin.—Thursday, 7th June. Lecture on "The Growth and Sculpture of the Alps," by Professor T. G. Bonney.

SOCIETY OF CHEMICAL INDUSTRY.—Monday, 4th June, 8 p.m. Papers to be read on "The Mode of Using Char in Sugar Refining," by Messrs. B. E. R. and J. A. R. Newlands, and on "The Adulteration of Olive Oil and Methods of Detection," by Mr. T. Bruce-Warren.

ROYAL SOCIETY.—Wednesday, 6th June. Annual (Ladies') Conversazione.

ROYAL UNITED SERVICE INSTITUTION.—Friday, 8th June, 8 p.m. Paper to be read on "Military Cycling," by Lieutenant-Colonel A. R. Savile.

PHYSICAL SOCIETY.—Saturday, 9th June, 3 p.m. Paper to be read on "The Analogy between Gases and Substances in Dilute Solutions," by Professor J. H. van't Hoff, communicated by Professor W. Ramsay. Exhibition of a Lantern by Mr. W. Lant Carpenter.

PRICES CURRENT, 31ST MAY.

Quotations at per ton, unless otherwise specified.

Do. at Hull (on quay)	5/–

Messrs. Carrick & Brockbank, Manchester, report as follows:—

COPPER.—Quotations for Chili spot parcels are irregular, and down to £80. 15s. per ton; three months, £77. 5s. to £76. 5s. Manufactured is unaltered, with little or no demand. There is still much uncertainty as to the future of copper. Chili bars are freely offered for delivery in three months below the price maintained by the French syndicate for spot copper. It is felt that this price is too high, and manufacturers are greatly hampered by it. Stocks continue to increase, and the copper trade is altogether in a most unsatisfactory position.

TIN.—Quotations for Straits are also lower; spot parcels, £85. 15s.; forward, £86. 10s. to £87. per ton, according to date.

LEAD slightly firmer. Spanish, £12. 5s. to £12. 7s. 6d. per ton.

SPELTER quiet, and without alteration.

WE understand that Professor Forbes having adjudicated upon the tenders received by the House to House Electric Light Supply Company, Limited, London, for three sets of alternating current dynamo electric machinery, the directors of the above company have decided to entrust the order to Messrs. Elwell-Parker, Limited, Wolverhampton.

JUNIOR ENGINEERING SOCIETY.—At the concluding meeting of the present session of this Society, held recently, a paper was read by Mr. F. W. Quick, C.E., on "The Elements of Stresses in Structures." Reference to diagrams and models assisted the author in his investigation of the character of stress to which constructional material, under various conditions and circumstances, was subject. An animated discussion ensued. Arrangements are now in progress for visiting several places of engineering interest in the vicinity of London during the summer months.

HOME INDUSTRIES.

MANCHESTER, 31st May, 1888.

The Iron Trade.—The iron trade continues to be very lifeless; no great quantity of material is being bought, and offers are only made at very low rates. The continued decline in the price of warrants both in Glasgow and Middlesbrough has its natural effect in this country, and there is a difficulty in maintaining even the present rates for local pig iron. As we pointed out a fortnight ago, the continued increase in stocks prevents a rise in prices, and unless the opening of the shipping season checks the further accumulation, it is probable that some curtailment of production will become necessary. The bar iron trade does not improve, and prices continue to be very low. Common bars may be obtained at £4. 17s. 6d. per ton, and marked bars are nominally quoted at £5. 5s., although less is being taken. The loom and spinning machine makers, however, are using a considerable amount of wrought iron. Steel is in good request, and both bars and boiler plates are being well sold, although at rather lower rates than were prevalent a few weeks ago. Steel hoops are quoted at £6 per ton for ordinary thicknesses such as are used for baling purposes. Steel castings are now more generally used than formerly, but the increasing competition in this business is reducing the prices; a general quotation for machine moulded wheels with plain teeth is now at 23s. to 24s. per cwt. The Steel Nut and Tube Company, who make a specialty of hollow steel bars of various sections, nuts, rigging screws, and similar goods, are very busily employed, and their business is rapidly developing. The goods are manufactured by patented machinery.

The Engineering Trades.—Almost every engineer in the district has been very busy during the past week with repairs, having taken advantage of the long Whitsuntide holidays. Otherwise not much business has been done, and very little new or prospective work has come to hand. Boiler makers and general millwrights continue to be well employed. Brass founders and copper smiths are suffering very severely, owing to the artificially enhanced price of copper, which checks the sales in all classes of goods. Locomotive builders are only moderately employed, and the amount of new work coming forward is very small. The condition of tool makers is gradually improving, and there is, generally speaking, a brighter prospect for this department. Machine makers are still as busy as ever, and a great many additional orders are coming to hand; prices, however, are difficult to raise.—Mr. R. Matthews is retiring from the well known firm of Messrs Goodfellow & Matthews, general engineers, Hyde, with which he has been connected for several years. The business, which is a large one, especially in connection will mill engines, hydraulic plant, and refrigerating machinery, will be carried on as usual by the remaining partner, Mr. Goodfellow, under the style of Benjamin Goodfellow.

Wages Disputes.—Consequent upon the success of the Oldham operative spinners, the Bolton workpeople are agitating for a similar advance of 5 per cent. Notices to leave are to be handed in on the 12th June, unless in the meantime the advance is conceded. While it is probably true that the coarser counts are now being spun at a profit it by no means follows that the finer counts which are spun in Bolton can be equally profitably produced, and there is ample reason to believe that the margin in these counts is not anything like so good as the operatives imagine.—The dispute at Blackburn has ended in a partial strike, though hopes were entertained that it would be settled by the adoption of a uniform list.—In the engineering trades the dispute between the moulders and their employers has been practically settled by plenty of substitutes being found for those who went out on strike.

The Ribble Scheme.—Following upon the opposition which was partially successful in the House of Lords, a petition has been prepared for presentation to the House of Commons, praying that until the report of Mr. Abernethy has been presented no sanction shall be given to the proposals to raise new capital. If the opposition is successful it will place the Corporation of Preston in a very awkward position, as they have already incurred a large liability in excess of that for which they have powers. At the present time the dredging of the river channel is only being ineffectively performed, and until the additional dredger ordered is put to work, cannot be thoroughly carried out. In the meantime the effect of the dredging has been to deepen the river channel behind the actual point of operations in addition to the deepening at that point, and if the works are stopped, Preston will be in the position of having an almost completed dock, access to which will be impossible for ships of large burthen.

LONDON, 31st May, 1888.

The Money Market.—Money is still plentiful, and it is expected to remain so for some considerable time to come. This week there was a good demand for accommodation in connection with the Stock Exchange settlement, although as a rule the rates of continuation were by no means heavy. This demand was met by an abundant supply of money, so that the rates for accommodation were not materially hardened. The new account on the Stock Exchange opened rather badly, at least in the more speculative departments. Government stocks and home railways were inclined to improve. American railways should recover again very soon, but there is little encouragement in that direction from Wall-street. The feature of this week was the sudden break in copper shares, which was probably due to the fact that the quotation for Chili bars for three months delivery is considerably below that for spot cash. The collapse in diamond shares was no doubt simply the inevitable reaction from the high pressure of the past few months.

Companies.—The following new companies have been registered since our last report: The South Durham Alkali Company, Ld., with a capital of £85,000, to manufacture alkali, caustic soda, soda crystals, muriate of ammonia, and other chemical products; T. & J. Leigh, Ld., with a capital of £250,000, to carry on business as cotton spinners; The Mather European Patent Bleaching Company, Ld., with a capital of £40,000; The New Belgrano (Buenos Ayres) Gas Company, Ld., with a capital of £200,000; Aërial Passenger Car Company, Ld., with a capital of £25,000, to acquire an invention for improvements in relation to wire rope suspension ways and carriages for the same; George Angus & Co., Ld., with a capital of £330,000, to carry on business as tanners and dealers in gutta-percha, &c.; The Alliance Aluminium Company, Ld., with a capital of £500,000, to manufacture sodium, potassium, aluminium, &c.; Wilson Mining Company, Ld. (United States), with a capital of £350,000; The British Columbia Smelting Company, Ld., with a capital of £65,000; The South African Gold Quartz Crushing Mills and Mining Exploration Company, Ld., with a capital of £60,000; and The London and Orange Free State Exploration and Mining Company, Ld., with a capital of £250,000.

Metals. — The symptoms which showed themselves previous to the recent fall in tin are now manifesting themselves in copper, the rates for Chili bars at three months being considerably lower than for cash. On the other hand, Straits tin is recovering, the rate for three months being higher than for cash.

Textiles.—The wool market shows greater activity, and the prices obtained for Australian and South African wool compare favourably with the rates at the last series of Colonial wool sales. The accounts from the manufacturing districts also promise well. The arrivals for next month's series are slow. There is but little business being done in Baltic hemp. A fair amount of Manilla hemp for arrival has been sold at somewhat harder prices.

Aluminium.—We had last week an opportunity of inspecting the exhibit of the Aluminium Company intended for the Melbourne Exhibition. The collection comprises a bust of Lieutenant-General Sir Andrew Clarke, R.E., and other works of art, besides a large number of articles for domestic and industrial purposes. The alloy used for all these articles contains aluminium, copper, bismuth, and nickel, the proportions being varied to suit the special requirements of each case. The alloy is known under the name of Webster's Crown Metal, and in preparing it the makers use commercially pure aluminium, produced under Webster's process, which requires the use of sodium. The latter is made by Castner's process, to which we have already several times referred. Among the industrial exhibits we noticed some highly finished fittings for railway carriage doors, and also some samples of wire rope, which is now being introduced for trawling, the metal having the great advantage of not being affected by sea water. We were informed by the manager of the company that the tensile strength of the drawn wire, as made for this purpose, is as high as 70 tons.

Railways.—The gross receipts of the twenty-three principal railways in the United Kingdom for the week ending 20th May amounted to £1,311,337 on 15,852¾ miles, as compared with £1,175,530 in the corresponding period of 1887, when the mileage was 15,737½ miles. An increase is thus shown in the mileage of 115¼ miles, or 0·7 per cent., and in the receipts of £135,807, or 11·5 per cent. The cause of the great increase in receipts is that the figures for the week include the Whitsuntide holidays, which always cause an advance over an ordinary week.

The Sugar Bounties.—The draft convention drawn up by the International Sugar Bounties Conference has been under the consideration of the different Governments concerned, and it is stated that the communications received have without exception been favourable to the adoption of the convention, which, with certain reservations, provides for the abolition of the bounty system.

Exhibitions.—Among the English exhibits at the Anglo-Danish Exhibition there is a model of an unsinkable man-of-war, invented by Sir Henry de Burgh Lawson, Bart., which is designed with a triple keel, with propellers working between these. It is claimed that such vessels can turn in their own length. On the ornamental water where the fountains formerly were, there is a boat worked by means of a "rudder motor," the invention of Captain T. B. Heathorn, of the Royal Artillery, which is an ingenious arrangement, and is intended mainly to be applied to yachts, for enabling them to beat against the wind. —A National Co-operative Exhibition will be held at the Crystal Palace in August, and the Council of the Society of Arts offer a bronze medal in each of the classes, which include engineering, cutlery, weaving, and metal work.

Finsbury Technical College.—The students' conversazione was held at this college on Friday last, when popular lectures were delivered by Professor J. Perry on "Magnifying Springs," and by Professor S. P. Thompson on "Polarisation of Light." A number of electrical firms sent specimens of their manufactures, and one room was lighted by the batteries of the Electrical Power Storage Company, and the staircase by a Gülcher dynamo. Mr. John Orchard exhibited appliances used in connection with military ballooning, including steel tubes made from one plate without welding for the carriage of compressed hydrogen.

GLASGOW, 31st May, 1888.

Metals.—The pig iron market has again taken a turn downwards. The quantity in store is advancing steadily, and foreign orders appear to be falling off. While the prices of German pig iron are, in that country, almost prohibitively high, in consequence of the action of the German syndicates, prices here seem to be altogether in favour of the "bears." In the early part of the week there was a good deal of unloading of copper shares. A decline was the natural result, Mason & Barry shares falling 12s. 6d.; Rio Tinto, 11s. 3d.; and Tharsis, 4s. 9d. The collapse or cessation of operations of the tin syndicate seems to have suggested the possibility of the copper combination following suit.

The Exhibition.—The attendance at the Exhibition bids fair to beat the record of provincial exhibitions. The average daily attendance during the first eighteen days has amounted to 37,111; as compared with the Colonial, 25,816; Manchester, 21,512; and Edinburgh, 19,418. It is understood that some English firms have succeeded in booking considerable orders, which they attribute to the fact of their having exhibited. On the afternoon of Friday last, the Bishop's Palace, which contains an archæological museum, and which constitutes one of the attractions of the Exhibition, was opened by the Duke of Montrose. The building, which is constructed after the manner of Old Manchester and Salford, Old London, and Old Edinburgh, is a reproduction of a Scotch baronial building, which was the castle or palace of the Bishop of Glasgow, and which occupied the site upon which the present Royal Infirmary was erected in the end of last century.

The Boundary Commission.—The Town Council of Glasgow has resolved to memorialise the Government, urging them to take the necessary steps to give effect by legislation to the recommendations of the commission as expressed in the recent report. The Council has also resolved to make a representation to the joint committee of both Houses of Parliament now sitting upon private bill legislation, in favour of a great diminution in the expenses of such legislation to the promoters and opponents of private bills. One of the magistrates has been appointed to give evidence before the committee.

Shipbuilding.—It is announced that Messrs. G. & J. Burns intend to supplement their fleet of Channel steamers by the construction of a couple of steamers to make a daylight passage between Ardrossan and Belfast.

(From our own Correspondents.)

LIVERPOOL, 30th May, 1888.

Engineering and Shipbuilding.—Advantage has been taken of the holidays to make any necessary renewals or repairs to the plant and buildings. There is an undoubted improvement in the different branches of the trade, although competition has reduced the prices to an unprofitable basis, and most of the shops and yards present a far livelier aspect than they did this time last year. Orders have been received for several large steamers, and a large number of engines of the old compound type are being converted into triple expansion engines, the iron boilers being replaced by steel ones, to reduce the extra weight in the plates required to work under the necessary increased steam pressures. Forced draught has proved so satisfactory that it is now being applied to the majority of the steamers when practicable.

Hydraulic Passenger Lifts.—The public has so appreciated the comfort and convenience of the high pressure passenger lifts at present fitted in offices and public buildings, that many of the old low pressure lifts are now being replaced by the high pressure balance lifts, and most of the new buildings in course of erection are being fitted with such lifts, the pressure being obtained either from a gas engine pump and accumulator or from the Power Company's mains; and as the latter are now rapidly extending their system it is always adopted when possible, on account of the greatly increased economy and other advantages. Two balance lifts are now being erected on the premises of the Liverpool, London, and Globe Insurance Company, and a second one for the Queen's Insurance Company, by Messrs. R. Waygood & Co., who are also erecting a number of lifts for the new Tithebarn-street Station, the Household Stores Association, &c.

SHEFFIELD, 30th May, 1888.

The Heavy Branches.—Last week there was comparatively little work being done, except in repairs and putting down new plant. Work has re-commenced again after the holidays, and in nearly all the shops there is considerable activity. The demand for Bessemer steel continues extensive, and within the past few days very large orders have been booked. The crucible steel makers are also doing a steady trade, and noted marks maintain their prices. At the blast furnaces there is little diminution of the output; but orders are not quite so plentiful, and the tendency of pig is to decline. In the armour plate mills employment is not so plentiful. Heavy machinery is, on the whole, in good request, and a great portion of it is for export. Stationary engines, pumping machinery, and

Digitized by Google

boilers are all on better order; and shipbuilding material and chains for bridge construction are yielding a great deal of employment. Perhaps the busiest branches of Sheffield trade, however, are the railway branches. Rails are being sent out in large quantities to distant markets, and tyres and axles are in greater demand for both home and foreign customers. One or two of the large English companies have just placed large orders for tyres, axles, and railway springs. There is great activity in the carriage and waggon building shops. The Midland Railway Company, a few days ago, sent extensive orders to Sheffield houses for railway material, and probably some of this is intended for plant on the Dore and Chinley Railway. A start has been made with this new line through the Peak, and a shaft has already been driven near Totley, for the tunnel that will go under the moors.

New Limited Company.—A company has recently been formed for the purpose of acquiring the business of Messrs. Oldham & Booth, engineers and millwrights, Hull, which was established more than a hundred years ago. A leading feature of the business is the manufacture of bone crushing mills and manure plant, and a trade in paint, cement, and flour mills has lately been developed.

LEEDS, 30th May, 1888.

Iron and Steel.—The manufactured iron trade is rather quiet; but there is an increasing call for Bessemer billets, and the steel trade, so far as Leeds and district is concerned, may be described as satisfactory. Orders are numerous for most kinds of heavy material. Machinery, girders, and agricultural implements are more freely inquired for, and the railway branches have not been so brisk for some time past. Messrs. Kitson have several very good orders on hand for locomotives, one being from the Great Indian Peninsular Railway; and they are also doing moderately well with tram engines. One or two firms are engaged on war and other heavy material, and at the foundries and rolling mills there is more work. Operations are to be resumed at the Aireside Hematite Iron Works, or rather steel works. A commencement was made some time ago, after plant valued at £200,000 had been put down, and very excellent steel was turned out; but the vast works were suddenly put in the market. They have been bought by a wealthy syndicate, and steel making on a very large scale will soon be carried on there. Engineers' tools and cut nails are both finding a ready market. For colliery plant there has been a more active demand, as the owners have taken the opportunity of making renewals during the idle days.

NORTH STAFFORDSHIRE, 30th May, 1888.

The Iron Trade.—Works have now generally resumed operations after the Whitsuntide holidays; but orders and specifications are scarce, and prices remain at a low and unremunerative level. For pig iron there is a somewhat improved demand, and stocks in some instances are being reduced; but prices do not alter from a basis of 34s. to 36s. per ton for forge iron at the works. Foundry pigs are being stocked in consequence of a falling off in the consumption of local foundries.

Canal Communication.—Much interest is just now being taken by local traders in the subject of canal carriage. Owing to its land-locked position, North Staffordshire is heavily handicapped in competition with other industrial centres. One example may suffice. The rate for pig iron to London is 12s. 6d. per ton, whereas the Scotch brands, with which this district competes, are conveyed by water for about half that sum. The experiments made last week by the London and North-Western Railway Company on a length of their Shropshire Union Canal, with a view to utilise locomotives as a propelling power, were on the whole very successful. Rails had been laid on the towing path, and a small locomotive from the Crewe workshops hauled six to eight boats at a speed of about six miles an hour. It remains to be seen whether the bridges and locks will prove insuperable difficulties to a further development of this scheme, but the officials express themselves as confident of success. The saving in cost if steam power were substituted for horses would be considerable.

SOUTH WALES, 30th May, 1888.

Colliery Fire.—Shortly after eight o'clock on Thursday evening last a large fire broke out at the Maritime Colliery, near Pontypridd, which endangered the lives of sixty-five men in the workings at that time. The fire originated in a large shed at the top of the downcast shaft, and soon spread to the pit framing, the heat and smoke being carried into the pit by the downward air current. The danger of firing the workings was removed by stopping the fan. The hot steam pipes in the downcast soon created an upward draught, and the fireman below arranged the doors to suit the ventilation in its reversed state. The men, who had previously felt discomfort from the smoke and heat, were now, through these judicious exertions, able to await with confidence the preparations for bringing them up by the upcast, an operation which was completed without accident.

Salvage Operation.—The Dundee Salvage Company have just succeeded in righting, by a novel method, the "Salatiga," of Rotterdam, which capsized during a squall in the East Bute Dock in April last. Huge logs of oak were fastened to the broadside of the ship, extending some distance beyond her bottom, and the protruding ends of the beams were loaded with about 40 tons of chain to act as a counterweight. The yards, masts, and similar structures aloft were removed, and the hatches and all other openings were closed by divers, who made them perfectly air tight. The powerful centrifugal pumps of one of the Dock Company's steamers then removed the water from the capsized hull, which righted herself when the contained quantity was insufficient to hold up the counterbalancing weight. The operation has cost £500.

BARROW-IN-FURNESS, 30th May, 1888.

Iron and Steel.—A further decline is noticeable in the hematite pig iron trade. The demand is less extensive from all sources, and makers are not nearly so well off for orders as they have been. The position of Barrow is an exception to the general rule, as both the iron and steel works remain very busy. There is likely to be a reduction in the output of the district, however, within the ensuing few days, as a protest and a check against the downward tendency of prices. To-day mixed numbers of Bessemer pig iron are quoted at 41s. 6d. per ton net f.o.b., and No. 3 forge at 41s. per ton, being a reduction of 1s. per ton on the week. The weaker tone of the market is clearly shown in the fact that the quotations asked by makers are practically those at which hematite warrants have been changing hands in the open market. Stocks of pig iron are still very large, and in this fact lies the reason of the lowering tendency of prices. In the steel trade a fair business is doing, but makers are not in receipt of so many inquiries as of late, and generally speaking the demand is not so pressing. There is a large output of steel rails, which are somewhat lower in price. Heavy sections are quoted at £3. 16s. 6d. per ton, and light sections of 30lb. to 35lb. at from £4 to £4. 7s. 6d. per ton net f.o.b. A fair business is being done at the hoop and wire works, and improved facilities have been provided for the development of what promises to be a large trade in steel forgings. There is not so brisk a demand as of late for ships' plates and angles, but makers are well sold forward. Current quotations show plates to be at £6. 12s. 6d., and angles at £5. 17s. 6d. per ton net f.o.b.

The Jute Trade.—The large jute works at Barrow are briskly employed. Indeed, there has been no scarcity of orders for a few years past, and under the present management it seems probable there will be a continuance of activity in jute spinning and weaving. Wages are not high for workmen and workwomen; but a considerable amount of employment is afforded to girls and young women who would otherwise find no employment at all in Barrow.

MIDDLESBROUGH, 30th May, 1888.

Pig Iron.—At the market held on 'Change yesterday there was a very good attendance, but the market was even flatter than it has been, the nominal price of No. 3 G.M.B. having fallen to 31s. 1½d. Warrants are 30s. 11d. cash, which is a more reliable figure, representing what actual business may be done. Makers, however, will not part with their iron under 31s. 6d.

Shipments of Pig Iron.—The shipments of pig iron continue to increase. Up to the 28th inst. they amount to 99,265 tons, as against 87,511 tons to similar date last month, which was considered uncommonly good, and 71,302 tons to the 28th of May, 1887. Germany and Holland are still the heaviest foreign importers, and Scotland beats them only by a few hundred tons.

Manufactured Iron and Steel.—There is no change in these industries. The rolling mills are going steadily, but there are few new inquiries, and still fewer new orders. Plates are quoted at £4. 15s., angles at £4. 7s. 6d., and bars at £4. 12s. 6d. per ton less 2½ per cent. discount. The steel works are steady on full time, but the demand is very quiet. Rails £3. 12s. 6d. per ton for heavy sections. The men are still locked out from the Darlington Steel Works, and are using the Mayor of Darlington as a means of reconciliation.

Shipbuilding.—The entire North of England shipbuilding trade is threatened with a strike on the part of the men for a rise of 12½ per cent. on wages and piece work alike. This the masters cannot see their way to grant. The men in this quarter have given in their notices, which expire on the 31st. The chairman of the masters being ill, has prevented a conference taking place to see if a compromise could not be arrived at. It is generally considered that the state of the trade does not warrant this movement on the part of the men.

SUNDERLAND, 30th May, 1888.

The "Lancashire Witch."—This screw steamer, which was specially constructed for the Liverpool and Isle of Man traffic, has come into her builders' hands again, and is now lying in the river, awaiting a purchaser. It is probable that she may be acquired for local passenger trading in the Australasian Colonies.

Shipping.—The recently published returns of the River Wear Commissioners show that during the month of April there was a falling off in the coal shipments as compared with April, 1887, probably due to the Tyne ports recovering the trade lost last year by the Northumberland strike. 324,314 tons of coal were shipped last month, as compared with 333,904 tons in the corresponding period of last year, showing a decrease of 6904 tons. The total revenue of the Commission shows a similar falling off, being £9,551. 14s. 7d. as compared with £10,163. 17s. 6d. During last week the quantity of coal shipped, 61,914 tons, was not so large as that exported during the previous week, when 72,968 tons were shipped. Of the total quantity, 29,890 tons were sent to foreign ports, and 32,024 tons coastwise. There were also exported during the week 820 tons of patent fuel, 265 tons of cement, 630 tons of lime, 66 tons of coke, besides glass, wood, &c. The imports included 2330 tons of iron ore, 447 tons of moss litter, 320 tons of silver sand, and large quantities of pit timber, deals, battens, spars, &c. The freight market is generally steady, and the homeward trade from the Black Sea continues to be animated.

NEWCASTLE, 30th May, 1888.

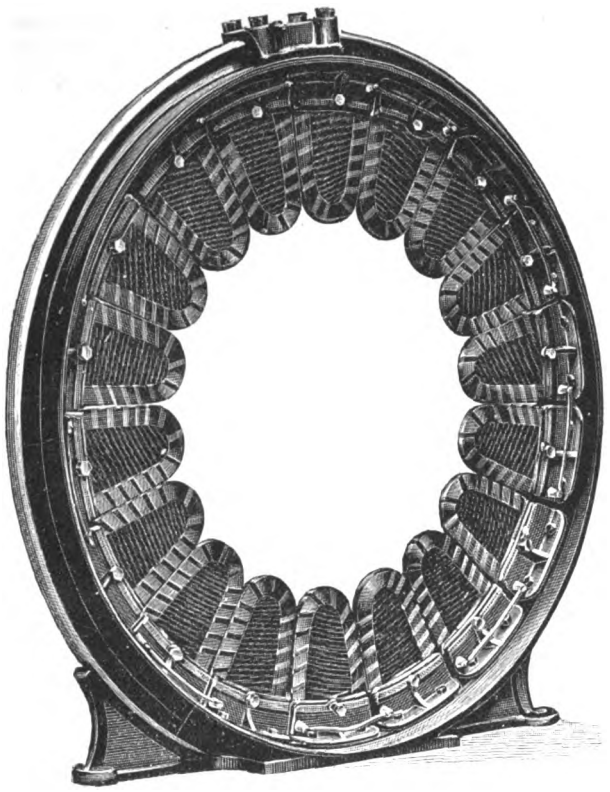
Shipbuilding.—Owing to the unsettled state of the relations between employers and employed in the shipbuilding industry, few new contracts have been entered into lately, and for the moment little disposition appears to exist among the leading shipbuilders to undertake additional responsibilities. Messrs. Palmer & Co. have at present nine vessels on the stocks, all of them being of large tonnage, and all but two in early stages of construction. The firm have succeeded in partially filling the places of the platers' helpers who went out on strike for an advance of wages some weeks ago, and fair progress is now being made with the work of the vessels in hand. Messrs. Readhead are keeping their five building berths almost constantly occupied, for no sooner is a vessel launched than the vacated place is being put in readiness for the reception of another keel. Two of the five vessels that are now on the stocks are in advanced stages. A large vessel, which has been built to the order of Greek owners, and which also has been engined by the firm, is now being fitted out beside the yard. Four vessels, that are to form an addition to the fleet of the "Gulf" Company, of Greenock, are now on the stocks, and one of them will shortly be ready for launching. At the Low Walker yard of Messrs. Armstrong, Mitchell, and Co. the pressure of work is still exceptionally great, the whole of the berths being occupied with vessels of large dimensions. Messrs. W. Richardson and Co. are among the extremely busy firms, and will no doubt be able to fully utilise their building accommodation for some months to come. There are some half dozen shipbuilding establishments on the river, however, that have still very little to do, from which circumstance it may be deduced that the development of activity in the industry has not yet reached its highest point.

Engineering.—The state of uniform briskness recently noted continues to exist in the marine engineering establishments, and the boiler shops connected therewith are also kept very actively going. In the locomotive shops only a limited business is being done; but at several establishments, where ships' pumps and other engineering specialties are manufactured, orders are very plentiful. Messrs. Noble & Lund, machine tool makers, are now exceedingly busy, having orders in hand for several planing and angle bending machines. The firm have also an order for a band sawing machine to cut iron or steel plates, &c., up to a width of 2ft. 6in. This machine, it may be stated, is intended for use in one of the largest engineering works in the country.

The Coal Trade.—The shipments of coal and coke at Tyne Dock for the week ending May 26th, amounted to 89,215 tons, being an increase of nearly 7000 tons over the shipments for the corresponding week of last year.

The Wages Dispute.—The platers' helpers did not return to work to-day at any of the yards; the lock-out has therefore become a strike. The ship joiners have also come out on strike for an advance of 3s. per week. There are in all about two thousand men on strike from the Tyne ship yards, and fully as many more are laid idle as a consequence.

BELFAST, 30th May, 1888.



Shipbuilding.—The yards still continue to be well supplied with work, and some new orders have been booked. The riveters in Messrs. Workman, Clark, and Co.'s yard have been out on strike for the past fortnight, in consequence of the employers not acceding to their request for higher rates of piece work wages. Owing to the state of the vessels on the stocks, the strike is causing considerable inconvenience to the other outside trades, and the men are gradually dropping out of employment. The strike is rather ill timed, as, of course, the work in hand was contracted for before there was any improvement in prices, thus leaving the margin for profit very small. This firm have now completed the four large dock caissons which they had in hand, and await the completion of the docks at Haulbowline and Belfast for their delivery. The splendid steamer "Arcadia," built by Messrs. Harland and Wolff for the Peninsular and Oriental Company, is now on her station, and gave most satisfactory results during the trial trips.

Engineers and Boiler Makers.—These branches are very fully employed at present, and some firms hold large orders. Marine engineers are exceedingly busy both on new work and on repairs. Messrs. James Reynolds & Co., of Belfast, are about to exhibit, at the Irish Exhibition in London, a new flax scutching machine constructed by them, and invented and patented by Mr. John Orr Wallace. It is very similar in action to an ordinary threshing machine, and its principal features are speed and effectiveness at a small cost, and the thorough removal of the woody portion without any waste or damage to the fibre.

FIELD MAGNETS.

THE BOARD OF TRADE AND SHIPOWNERS.

ONE of the most remarkable parts of the report of the Royal Commission on Loss of Life at Sea was a paper by Mr. John Warrack, in which he criticised with great vigour the proposed legislation of the Board of Trade. In the last paragraph of that paper, he said "The whole policy of the Board of Trade's scheme tends to the suppression of British shipowning enterprise. By its interference with the ordinary rights of shipowners in their contracts as to insurance and the carriage of goods, it would prevent them from managing their ships by the common rules of commercial prudence. By its proposed 'arrangement' of the law, it would let loose upon them every possible claimant, and tie up their hands for their own defence. All this means the inflicting on British shipowners an enormous dopreciation of their property, by rendering their ships of little use for commercial purposes. It would give foreign flags not under such disabilities (and some of them aided by bounties and subsidies from their Governments) an incalculable advantage as against British ships." If these were the opinions of a single individual, we might put them aside as being exaggerated and one sided; but when we find them indorsed by the great body of shipowners of such an important port as the Clyde, we are compelled to believe that there must be good reasons for them being held and expressed.

About three years ago, when the Clyde shipowners were called upon to nominate a gentleman to represent them on the Royal Commission on Loss of Life at Sea, they unanimously agreed to appoint Mr. John Warrack, of Leith, and a few days ago that gentleman was presented by the Clyde shipowners with a handsome testimonial in recognition of his services to that Commission, and especially of what was called his admirable exposition of the questions under consideration, as contained in the above mentioned paper, which was said to express a truly excellent defence of the shipowners' position. Mr. Edward Martin, the President of the Clyde Steamship Owners' Association, in supporting Mr. Alexander Allan in presenting Mr. Warrack with the testimonial, gave an account of what had been done by that gentleman, and he spoke as the representative of an association having the highest membership, embracing the largest number of vessels, and, with one exception, having the largest tonnage in the world, and he wished to tell Mr. Warrack, not only how they appreciated and were satisfied with his services, but that they considered the honour he had done to himself had reflected, not only on the shipowners of the Clyde, but upon the shipowners of Scotland. Mr. Warrack worked under difficulties from the very first. The shipowners only got what they considered their proper representation on the Commission, after a threat by Mr. Joseph Cowen that he would move an amendment to the Queen's Speech, unless the reasonable demand of the shipowners was conceded. This was only screwed out of Mr. Chamberlain after it was clear that a refusal would involve the defeat of the Government. Mr. Martin was of opinion that never had a Royal Commissioner such an uphill battle to maintain the honour and honesty of his calling as Mr. Warrack; for in the first place he had to face, in a packed Commission, an able and powerful Cabinet Minister, who had created a strong public feeling by sensational speeches, misleading figures, and unreal facts. This Minister was, again, backed up by all the information and influence which a great Government Department could bring to bear, and which was responsible for proving the truth of the misleading and inaccurate statements which had called the Commission into existence. The charges which that Government Department tried to establish before the Royal Commission were: (1) That the loss of life at sea was excessive and increasing, and was to a great extent preventable; (2) that the present state of the law of insurance rendered it possible for owners to make a profit by losing a vessel, and that this is an incentive to carelessness; (3) that over-insurance and under-manning are common practices, and that the power of over-insurance and freedom from responsibility may contribute to the loss of life at sea. The Board of Trade proposed to remedy these alleged abuses by suggesting to alter, in what shipowners considered an impracticable manner, the law of insurance, which they said was the outcome of generations of experience, which had worked well, and upon which the British mercantile marine had been built up. Further, to increase, in the event of a loss, the responsibility of an owner, and to attach an invariably criminal responsibility, and assume him to be guilty until he proved his innocence. Shipowners joined issue with the Board of Trade on all the points raised; and they produced evidence before the Commission to show that the statistics of that Department were misleading, untrustworthy, and useless as a basis for legislation; that loss of life at sea was not only not increasing, but decreasing; that over-insurance and under-manning were not common; that owners had a direct and substantial pecuniary interest in bringing their adventures to a safe termination; and that the power of over-insurance did not contribute to the loss of life at sea; while, on the other hand, they believed that the proposed remedies of the Board of Trade for decreasing loss of life were not only unsuitable, but in many cases absurd, and that certain regulations enforced by the Board of Trade directly contributed to, and were immediately followed by, an increase of loss of life at sea. Mr. Martin concluded by saying that what shipowners now demanded was the suppression, or rather the elevation, of a certain high official to some more ornamental, if less powerful, sphere, and an entire re-organisation of the Marine Department of that antique and quaint anomaly called the Board of Trade.

These are very strong opinions, and in replying Mr. Warrack said that he was glad to find that his sentiments were thoroughly in accord with the sentiments of those who had called him to that position. He pointed out that the origin of the whole dispute was the publication by the Board of Trade, in 1883, of a manifesto, in which they set forth in the very strongest terms that they were incompetent to cope any longer with the increasing number of shipwrecks, and they went on to say that the only remedy for that was either to extend their powers indefinitely, which would never have done, or else to go on with legislation the effects of which would have been to expose shipowners to liabilities in every possible quarter without it being possible for them to vindicate themselves. A very significant fact, however, was this, that although the Board of Trade had no greater powers than it had before, and although the legislation it had proposed had not been carried out, the loss of life and property at sea had for years gone on steadily diminishing. The increase of some years ago, which frightened the Board of Trade officials, seems to have been caused by the transition from wood to iron, and from sails to steam, and the consequent difficulty of finding men who were able to take charge of the ships under the new conditions. When we remember that the gross annual receipts from our carrying trade amount to an immense sum, in fact more than our total net receipts from railway working, considerably more than the gross annual value of our coal products, and about as much as the present agricultural rent of the country as a whole, we see that it is one of the most important industries of the country, and therefore care must be taken that no legislation is allowed which unduly hampers its development. We have in this article given the views of a large body of shipowners, and on another occasion we may consider how far these are consistent with the interests of the general public, which are supposed to be entrusted to the care of the Board of Trade.

AN ELECTRIC ORGAN.

A NEW electric organ has been erected at the back of the stage of the Burg Theatre, in Vienna, and is connected by a cable with the orchestra, where the key board is situated. The cable is long enough to admit of altering the position of the key board within a radius of 30ft. The organ has been built by Messrs. Rieger Brothers, of Jägendorf, and the signals are transmitted from the key board to the relay lever by five Callaud cells.

To Correspondents.

All communications intended for insertion in this Journal, or relating to Editorial matters, should be addressed to "THE EDITORIAL DEPARTMENT," either at the Manchester or the London Offices, and must, in all cases, be accompanied by the name and address of the writer. No notice will be taken of anonymous letters.

We cannot undertake to return manuscripts or drawings, and must request correspondents to keep copies.

Industries, VOLS. I., II., & III.

From July, 1886, to December, 1887.

A few Copies, handsomely bound in half calf, gilt lettered, may now be had at the Head Office, 70, Market-street, Manchester, Price 20s. each.

Industries:

FRIDAY, 1ST JUNE, 1888.

GERMAN GUNPOWDER IN ENGLAND.

AN article in the *Standard* newspaper, the inspiration of which it is not difficult to trace, directs public attention to a serious scarcity of gunpowder in the Government stores. The question is of industrial as well as political interest, and in the former relation no less than in the latter, it calls for instant remedy. The deficiency in special qualities of gunpowder is due to the rapid progress in the science of gunnery made within the last few years, though its present existence cannot be justified, or even defended, upon that ground. The gunpowder of to-day is not that of even ten years ago. The requirements of modern artillery have created a necessity for an explosive different in its behaviour under combustion and more under control than the powder of former times. The end to be attained is to impart to the shot the highest possible velocity without dangerously straining the gun. The qualities requisite to fulfil this condition are combined in a satisfactory manner in "cocoa" powder, so named from its resemblance in colour to cocoa. This, which is nothing more than a slightly modified form of the old black gunpowder, is a German invention, though, if we may believe the writer of the article in the *Standard*, the suggestion came originally from Captain Noble, of Elswick. Great care has been taken to surround the manufacture of cocoa powder with mystery, while its merits, on the contrary, have been loudly proclaimed from the housetops. Whether or not these merits have, as some eminent authorities contend, been exaggerated, is a question into which we will not now enter. Cocoa powder, such as it is, has been adopted by the British Government for heavy guns, and to this fact, combined with certain contracts which we are about to comment upon, is due the scarcity of which complaint is rightly made. This state of things is a danger and a disgrace; a danger, because in case of war it would seriously weaken our means of defence; a disgrace, because it is an admission of inability on our part to keep pace with our rivals in a matter that is of a purely industrial character. How it came about that only the Government mills at Waltham Abbey, and the German Manufacturing Company, established since 1884 at Chilworth, in Surrey, are now producing this powder, is the question we now purpose to answer.

It is a fact within our own knowledge, and therefore presumably within the knowledge of the Government officials, whose duty it is to keep themselves informed on such matters, that British manufacturers, or at least some of them, are capable of making a powder possessing all the qualities of "cocoa" powder or even "cocoa" powder itself, without going to the Germans for instruction. Their ability to do this has been demonstrated in one instance by the actual manufacture of such powder as verified by the Government tests. Why then have our military authorities made themselves and the nation dependent upon one newly formed manufacturing company which, with the most liberal intentions, we cannot describe as English. We have derived some amusement, and perhaps a little instruction; from the clumsy efforts of the *Standard* writer to show that the Chilworth Company is not essentially German, a mere affiliated offshoot of the Westphalian Gunpowder Company. Better evidence is needed in support of this view than the fact of two Englishmen being on the Board of Direction. Moreover, the statement that "certainly no money grant has been made" by the British Government to the Germans for the possession of their secret, is not likely to gain belief in any sense beyond the strictly literal one. The Germans are an astute people, and are not yet to be credited with that sublime disinterestedness which cheerfully foregoes the *quid pro quo*. When the invention began to be noised abroad the British Government sent over to Germany a sort of committee of inquiry. This committee was permitted, on a certain day after due preparation had been made, to walk over the factory in which the "cocoa" powder was being manufactured, on condition that a large order should be given. But having failed to make themselves master of the trade secret they were sent to discover by such means as this, they were fain to approach Herr Heidermann and his associates in a more business-like way. These second negotiations resulted in a bargain which the Germans probably have not had cause to regret. It scarcely falls within the scope of this article to set out these terms in detail. We will merely remark thereon that the same terms failed to tempt the more astute Americans. Besides, it is not against the payment, whether directly or indirectly, of large sums of money that we protest. Our objection lies principally against the terms of the contract, which practically keep the whole of this manufacture in German hands, to the express exclusion and immense injury of our home industry. Waltham may, indeed, manufacture as much as it can; but all purchases of powder are to be made of the German Company at Chilworth. Under no circumstances may our Government officials, to whom the trade secret has been confided, reveal it to a British manufacturer. Hence the scarcity of powder, with its danger to the nation; and hence, also, the disgrace and injury to British industry.

But without infringing the terms of the contract, so hastily entered into, there was a remedy. All that was necessary was to encourage British manufacturers to produce a powder possessing the same qualities as that for which the nation has paid so high a price. Some of our leading gunpowder makers at once set to work; but every advance on their part was met by the Government officials with a rebuff. In spite of such discouragement, one great firm at least persisted in its efforts and achieved success. Others have given up the struggle. Experiments of the character in question involve heavy expense. Is it to be expected that manufacturers will incur so great an outlay, if the early and perhaps only partially successful endeavours meet with cold neglect, or worse, with a hostile reception at the hands of the Government, who alone can be their customers for goods of this nature? Why do the authorities, who submitted so readily to the oppressive condition of the Germans, manifest such stubborn unwillingness to afford the smallest aid or encouragement to our own manufacturers? Native industry is not so treated abroad. Imagine the German Government making itself dependent upon an English firm for what can easily be produced at home! The Americans, instead of rushing into a contract with Messrs. Heidermann & Co., first appealed to their own powder makers, who were not long in producing what was asked for. The

Digitized by Google

Standard writer admits that "there are excellent makers of gunpowder in this country who only require encouragement in order to develop their resources. That no doubt other factories besides that at Chilworth will be stimulated to improve the make of powder, &c." This is true enough. But where is the stimulant to come from? This is a question which just now presses for an answer both in the interests of the British powder makers, and in those of the nation at large. We are informed that further improvements are being made at the Chilworth works. This is not surprising, since the German company knows that its produce is sure to find a ready customer in the British Government. British manufacturers, on the other hand, know with equal certainty that no such market is open to them. This is the state of things to which we have been brought, and we protest earnestly that it is humiliating to us as a great industrial people, and intolerable to one of our important national industries.

OUR RAILWAYS AND THE STATE.

The motion which was recently brought forward in the House of Commons, by Mr. Hugh Watt, "That in the opinion of this House the time has arrived when the Government should appoint a committee or royal commission to take into consideration the question of acquiring the railways of the United Kingdom in accordance with the provisions contained in the General Railway Act of 1844," received so little support that it was negatived without a division. The question of State purchase is, therefore, not likely to be revived in the House for some time, and the attention of our legislators will probably be confined to the consideration of the regulation of railways by such measures as the Railway and Canal Traffic Bill now before Parliament. Mr. Watt, in his speech introducing the motion, enumerated some facts which ought to be known and remembered. After giving a brief history of the question, he directed attention to the present position of railway enterprise in this country. According to the latest published returns the total capital employed in the railways amounted to 828½ millions, the total receipts from all sources exceeded 66½ millions, and the net receipts 30 millions. Of the total stock, the ordinary stock exceeded 305 millions, preferential and guaranteed stock 314½ millions, and debenture stock and loans 208½ millions. The amount which had been paid by way of dividend upon the ordinary capital exceeded 12 millions, upon preferential and guaranteed stock 13 millions, upon debenture stock and loans, nearly 9 millions. The average rate per cent. upon ordinary stock had amounted to 3·94; upon preferential stock to 4·14; and upon debenture stock and loans, 4·18. The average rate of interest had, therefore, slightly exceeded 4 per cent. The current rates in the chief railway countries were as follow: In Sweden, 30s. 4d. per ton per mile; France, 12s. 10d.; Great Britain, 11s. 3d.; Holland, 9s. 10d.; Austria, 9s. 3d.; Italy, 9s.; Germany, 7s.; Belgium, 6s. 10d.; United States, 5s. 3d. The English rates were, therefore, nearly 20 per cent. above the average Continental rates, and more than double those current in America; but if we take the two Continental countries which had control of the railways, we found that our rates were 85 per cent. above those of Belgium, and 60 per cent. above those of Germany, showing the enormous extent to which our traders and manufacturers were handicapped by the present system, as compared with our two chief rivals. The terminal charges were also much higher in England than in other countries. He then went on to argue the advisability of the State purchasing the railways in this country, and in addition to pointing out the difference in favour of foreign manufacturers in their own countries, he complained that it was notorious that railway companies in this country had offered inducements in rates to Continental competitors for the importation of their products, to the great disadvantage of home manufacturers.

Mr. Bolton, the chairman of the Caledonian Railway Company, admitted that undoubtedly cases could be found in which the rates charged on the Continent compared favourably with those in this country; but they had to consider not only the rates charged, but also what work was performed for those rates. Speaking as a railway shareholder, and as one with many years' experience in the management of railways, he would say for himself, and many of those associated with him would agree with him, that they would welcome very heartily a scheme for the purchase of railways by the Government if they considered only their own pecuniary interests; but he was of opinion, if he could for a moment transpose himself from the position of a railway shareholder into that of a member of the general public, that the public by the purchase would not enjoy the advantages in the matter of railway travelling which they now had. He argued that if the railways had been acquired by the State twenty-two or twenty-three years ago, as Mr. Watt urged they should have been, that the country would not now have been covered with such a network of railways as now existed. After Sir M. Hicks-Beach and others had spoken against the proposal, Mr. Gladstone said that Mr. Watt had not misstated the general intentions of the Act of 1844, which was to preserve the freedom of the State in regard to railway companies; but he pointed out that the railway system had extended much more rapidly and widely than the promoters of that Act ever anticipated. He had always thought that if the purchase of railways could have been dealt with as a merely financial operation, that is to say, if it had been practicable that the Government could have been owners of the freehold and permanent way, and that active and vigorous commercial companies could have taken the working of the railways under Government, there would have been a great deal to say in favour of that operation. But then came the question whether leasing was a practical system, and he was afraid that the commercial mind of this country had arrived at the conclusion that it was not, and that if the Government owned the railways the Government must also be managers of them. He, however, entirely agreed with those who had objected to the proposal that the difficulties incidental to that system were conclusive against it. The Government of this country was the heaviest laden government in the world. No other government had such an extent, diversity, and complexity of functions, and for them, unless in the case of the strongest necessity, to load themselves with an operation involving the taking of what might be called roughly a tenth part of the property of the country invested in railways, and then become responsible for their management, was a proposal which could not seriously be entertained by Parliament. He hoped, however, that Parliament would exercise its best abilities in the reasonable control of the railway system, and that some attention would be given to canals.

Mr. Gladstone's arguments tend in the direction of the proposals of those who simply wish all our legislation to have a no-government-interference tendency, except so far as the interests of the whole community are involved, and who would enlarge the field of private initiative. The railway system of Europe—which includes a confederation of a score or so of separate societies—involves the direct transport of passengers and merchandise, over a great many lines. That these were built independently and federated together without the interference of any Government, or even a Central Board of European Railways, is a striking example of what can be done by mere agreement. Fifty years ago such an arrangement would have been pronounced impossible. Who shall say that fifty years hence sufficient progress will not have been made to enable the whole people—that is, the State—to manage the railway system for the benefit of the community?

In the meantime every effort should be made to remove inequalities, especially those which tell in favour of our foreign competitors. The recent Conference between the London Chamber of Commerce and the representatives of several of the railway companies in regard to the Railway and Canal Bill, showed most distinctly that the latter have recently shown themselves more amenable to reason than they formerly were; and this in itself is a sign of the time, and an admission of the growing power of the commercial element. The points under discussion referred to preference rates, terminal charges, and canals. The first of these admittedly gives an advantage to foreign manufacturers, the second item is in many cases too high. With regard to canals, as we pointed out in a recent article, we have too much neglected a cheap method of transport for heavy and bulky goods; and we have made a further mistake in allowing so many of our canals to fall under the control of the railways. The pressure of competition, however, is forcing these and other subjects to our notice, and in the future they will doubtless receive more attention than they have for some time past.

THE NAVAL DEFENCES OF THE UNITED KINGDOM.

An interesting and most opportune lecture was delivered on the 18th ult., at the United Service Institution, by Rear-Admiral P. H. Colomb, on the Naval Defences of the United Kingdom. The gist of the lecture was that in all our present deliberations the assumption was made that the navy would fail in its old historic *rôle* of safeguarding the kingdom, and that instead of increasing its efficiency we, as it were, gave it up as a bad job and spent our money in other directions. In support of this, the report of the Royal Commission of 1860 and the later official utterances of Mr. Stanhope's Committee were both quoted, with a view to show that in each case the temporary absence or disablement of the fleet was regarded as a possible contingency, while the possibility of an organised system of naval defence was completely ignored. The lecturer pointed out that in even more critical times than the present, such a system not only existed, but very effectually fulfilled its purpose. The lecturer showed that while both Lord Howe and Lord St. Vincent effectually protected the coast, the latter also protected the commerce, and he demanded that those who so loudly called for the expenditure of public money on fortification, should at least show some *primâ facie* cases for the always assumed possibility of naval failure. Lord St. Vincent's system started with the broad principle that these islands were merely the capital of a vast water territory, whose frontiers were the enemy's coasts; that the exits from his ports were to be held by us as the gates of the empire, and consequently our first line of defence was our blockading squadrons; behind them was a reserve fleet, which would attempt to sweep the sea of any vessels that might evade the first line, and behind this second line was a reserve of coast defenders. As long as this triple line held command of the sea, we need not fear territorial attacks, as all naval history shows territorial attacks to be impossible without the undisputed mastery of the waterways, and our commerce and ships bringing food supplies would be comparatively safe from attack. This system of Lord St. Vincent's depends merely on the efficiency of the navy; that being granted, all else will follow, just as much in 1888 as in 1803, for the fleet that is stronger under sail will also be stronger under steam, and all the later applications of electricity are on the side of the coast defenders. Nor is there now any fear of a blockading fleet being blown off the coast by stress of weather. The American Civil War gave an undisputable proof of the perfect efficiency of a blockade under steam. The Federal navy, for nearly four years, observed a coast line of 3500 miles, including 189 ports, with complete success, and the number of steamers captured or destroyed by them amounted to three-fifths of the whole number of steamers of 100 tons and upwards now possessed by France.

As practically carried out in 1803, Lord St. Vincent's measures were a triumphant success in all the main points; but at the same time the second line of defence somewhat failed in its purpose, as it was not sufficiently complete, and once a raider escaped the blockading squadron, she was able to do a good deal of damage before her capture or destruction. On this head the Admiral remarked: "If the 'despicable' privateer eighty years ago could make such havoc when shipping was thin and winds uncertain, what grounds have we for supposing that the equally 'despicable' raider will not in a future war do far more mischief in the much larger and richer field now open to him. Plainly none. That sort of attack on our commerce is as certain as any operation of war that can reasonably be predicted. The defence must be naval; but to be at all effective the defending ships must be so numerous that I do not see how the regular navy can possibly undertake it. Our noble chairman (Lord Cowper) has looked to a system of local volunteer effort as alone competent to deal with such a difficulty, and I have fully agreed with him. We believe that given local effort turned in that direction, a complete guard of our territorial waters can be established by the volunteer system, using chiefly the selfsame class of vessel that might be brought against us. My conviction is that the mere existence of such a system will prohibit the attempt to test its powers, and that even with an incomplete blockade, the commerce near our shores would be tolerably secure." In conclusion he pointed out that though Lord St. Vincent's plan was a possible and effective one, we were not, at the present time, sufficiently strong to carry it out, even in a war with France alone, but would have to fall back on that of Lord Howe, and concentrate the naval force at home in a defensive, expectant attitude, which would practically mean the abandonment of our commerce, though our shores would be perfectly secure.

A lengthy discussion followed the paper. Colonel Sir Charles Nugent pointed out the necessity of land defences, and reiterated the argument that we must provide for a possible naval disaster. He frankly admitted that money was badly wanted both for military and naval defences, and both departments should get as much as they could; but he was prepared to uphold the conclusions of the Defence Commission of 1860. General Brackenbury followed in the same strain. Several distinguished naval officers supported the statements of the lecturer, who in his reply advocated that money should only be spent on fortification after the rule of the sea had been secured.

We have just received an illustrated catalogue which has been issued by Messrs. Lucas & Davies, 21, Charles-street, Hatton Garden, London. This catalogue will be found useful by amateurs and inventors, as it contains a description and price list of various engine models, and also of the special castings and forgings used in the construction of the models.

THE PHYSICAL SOCIETY.

At the last meeting of this Society, Professor Ayrton read a note by himself and Professor Perry

On the Governing of Electromotors.

In 1882, the authors worked out and published a method for obtaining a constancy in the speed of an electromotor with a varying load, based on a combination of a motor with a brake dynamo which re-converted the surplus mechanical into electrical energy. After passing through various stages of developments, the arrangement finally adopted consisted of an electromotor having the field magnet wound with a shunt, and a series coil traversed by the current in opposite directions, so that the magnetisation of the field magnet was that due to the difference in the number of ampère turns in the two coils. This method had been re-invented in France by M. Deprez, and in America by Mr. Sprague, and had been submitted to exhaustive tests by Dr. Frölich; but the authors had not attempted to develop it further, owing to the waste of power which was necessarily involved in the use of a demagnetising coil. The original method was applicable either to the supply of constant current or of current at constant potential difference; but the authors noticed recently that in the former case the original equations were capable of giving a solution in which the demagnetising coil was dispensed with, and yet a constant speed obtained, together with the high efficiency of a well made dynamo. As it was only required to determine whether or not a certain combination would give a certain required result, the equations are simplified by neglecting saturation, and therefore the results obtained cannot be applied without correction to actual practice. Let E be the back e.m.f. in the armature of a motor running at a speed of n revolutions, p a term depending on the permanent magnetism of the iron of the field magnet, S the current through the series coil, q the number of turns in it, Z the current through the shunt coil, and t the number of turns in it.

Then $$E=n(p\pm qS\pm tZ) \quad \ldots\ldots\ldots\ldots (1)$$

the upper or lower sign being used according as the current in the corresponding coil assists or opposes the permanent magnetism.

Let s and z be the resistances of the series and shunt coils respectively, a the resistance of the armature, and A the current in it, then for a short shunt machine

$$E=Zz-Aa \quad \ldots\ldots\ldots\ldots\ldots\ldots (2)$$

and for a long shunt machine

$$E=Zz-A(a+s) \quad \ldots\ldots\ldots\ldots\ldots\ldots (3)$$

and in both cases, if C is the constant current supplied to the motor,

$$C=A+Z \quad \ldots\ldots\ldots\ldots\ldots\ldots (4)$$

In the former case C=S, so that equations (1), (2), and (4) give $$n\{p\pm qC\pm t(C-A)\}=(C-A)z-Aa \quad \ldots\ldots (5)$$

In the latter case S=A, so that equations (1), (3), and (4) give

$$n\{p\pm qA\pm t(C-A)\}=(C-A)z-A(a+s) \quad \ldots (6)$$

When n and C are given, equations (5) and (6) have to be satisfied for all values of A. Thus, for a short shunt,

$$\pm n(-tA)=-A(z+a) \quad \ldots\ldots\ldots\ldots (7)$$

and for a long shunt

$$\pm n(q-t)A=-A(z+a+s) \quad \ldots\ldots\ldots\ldots (8)$$

Now n, t, q, z, a, and s are all necessarily positive, and t is always larger than q, so that the positive value of tZ in equation (1) is the one which must be taken, *i.e.*, whatever the arrangement of the series coils, the shunt coil must be a magnetising and not a demagnetising one. In the paper on "Electromotors and their Government," by the same authors, in Vol. XII. of the Journal of the Society of Telegraph Engineers, they had already pointed out that the solution for constant current was a shunt motor with a series demagnetising coil; but in a standard English treatise the only solution for constant current with which the authors have been credited, was the impossible one of a series motor with a shunt demagnetising coil, which would require the speed to be negative, or the armature rotation to be reversed, which would simply turn the combination into a shunt motor and series demagnetising coil.

In another important English work the method is given correctly, but it is stated that it would not work, because if a greater load were put on, the motor would slow down, the back e.m.f. would decrease, and less current would flow through the shunt coil, thus weakening the field magnet, and, therefore, further diminishing the speed of the motor, which would thus be brought to rest or possibly reversed. The explanation of the apparent anomaly that to maintain the speed of a motor constant the field must be weakened when the load is increased, is, of course, that the power depends on the current through the armature as well as on the strength of the field, and when the latter is diminished, the former is much increased.

For a simple shunt motor supplied at constant potential difference V, $V=Z/z$, $E=Zz-Aa$, and also

$$E=n(p+tZ) \quad \ldots\ldots\ldots\ldots\ldots (9)$$

So that $$n\left(p+t\frac{V}{z}\right)=V-Aa \quad \ldots\ldots\ldots (10)$$

The left side of this equation is constant when n and V are given; while the right side is variable, as A depends on the power given out by the motor. The solution which makes the equation true independently of the value of A, is clearly the well known one of making a very small; but the authors have elsewhere given reasons against making the resistance of the armature of a motor as small as that of a dynamo armature. If then this solution be rejected, a negative term proportional to A must be added on the left hand side, and this is most simply done by adding a series demagnetising coil, when equations (9) and (10) in their more general form become respectively

$$E=n(p-qA+tz)$$

and $$N\left(p-qA+t\frac{V}{z}\right)=V-A(a+s).$$

The latter will always be satisfied for any value of A if

$$n=\frac{a+s}{q}.$$

When the supply is a constant current, the equations for a simple shunt motor are

$$E=n(p+tz)$$
$$E=Zz-Aa$$
$$C=A+Z$$

which give

$$n\{p+t(C-A)\}=(C-A)z-Aa \quad \ldots\ldots\ldots (11)$$

and which will always be satisfied if

$$n=\frac{z+a}{t} \quad \ldots\ldots\ldots\ldots\ldots (12)$$

So that a series demagnetising coil is unnecessary.

Substituting this value of n in equation (11), gives us the current for which the motor governs

$$C=\frac{np}{z-nt}=-\frac{np}{a}.$$

The terminals of the motor must therefore be reversed. This will reverse the current round the field magnet; but it must not reverse the residual magnetism, or p would also become negative. The core of the electromagnet must therefore be of steel so strongly magnetised that the shunt current does not reverse the polarity, and the permanent magnet and rotating armature will form a brake dynamo, while the shunt coil and the armature will form the motor. This is simply one of the solutions (theoretical, of course, not practical) given in the paper referred to. To obtain a practical solution alter this equation so that when the speed equation (12) is satisfied, equation (11) gives a positive value of the current, which may be done by adding to the right side of the equation (11) a positive constant term e numerically greater than np, for then

$$n=\frac{z+a}{t}$$

and $$C=\frac{e-np}{a}$$

for all values of A. This may be effected by introducing accumulators of an electromotive force e into the armature circuit, and joining them up in such a manner as to assist the main current C. The resistance of the armature circuit will then be increased by a value a^1 (being that of the accumulators), so that the final equations to determine the speed and the constant current at which the motor governs, will be

$$n=\frac{z+a+a^1}{t} \quad \ldots\ldots\ldots\ldots\ldots (13)$$

$$C=\frac{e-np}{a+a^1} \quad \ldots\ldots\ldots\ldots\ldots (14)$$

This solution is a practicable one, and, moreover, it does not require many accumulators, for np, the back e.m.f. of the motor due to the residual magnetism alone, will be small if the core of the field magnet is of soft iron, and a and a^1 need not be large, so that C can be made as large as required without giving a very large value to e.

The essence of this method consists in combining a shunt motor with a store of electric energy in the armature circuit; this energy being, as shown by the equations, automatically dealt out to assist the motor, exactly in proportion to the power required to keep the speed constant as the load is varied. The store is easily maintained by reversing the connections of the accumulators when they are disconnected from the motor, and the motor is at rest, and leaving the accumulators to be charged without supervision by the constant current which is continuously supplied.

At the same meeting, the Secretary read a note by Professor S. P. Thompson,

On the Formulæ of Bernoulli and of Haecker for the Lifting Power of Magnets.

Bernoulli's empirical rule is given by the formula

$$P=a\sqrt[3]{W^2}$$

where P is the lifting power or pull exerted by the magnet in contact with its keeper, and W the weight of the magnet. Haecker wrote the formula

$$P=a\sqrt[3]{W^2}$$

and taking the German pound as the unit of mass, found that a varied according to the quality of the steel, and the intensity of magnetisation from 8 to 10 for bar, and double these values for horseshoe magnets; so that a steel horseshoe magnet weighing 1lb. would lift from 16lb. to 20lb.

Van der Willigen repeated the investigations with Haecker's own and other magnets, and arrived at the formula

$$P=bK\sqrt{A}\sqrt{\frac{L}{A}}\frac{L}{l}$$

where b is a constant depending on the quality of the steel and the intensity of magnetisation, K the perimeter of the polar surface, A its area, L the distance between the poles, and l the mean of the interior and exterior lengths of the bar. For similar magnets $K\sqrt{A}$ is proportional to the surface A, so that according to this formula the lifting power of similar magnets is proportional to the polar surface multiplied by a correcting factor depending on the proximity of the poles. Van der Willigen found that b, which is virtually identical with Haecker's a, varied from 19·5 to 22·5.

Now, in similar magnets the linear dimensions are proportional to the cube root of the weight, and the polar surface is proportional to the square of the linear dimensions. Therefore for similar magnets both formulæ mean simply that the lifting power is proportional to the polar surface, which we know from Joule's and subsequent researches to be approximately true for equal intensities of magnetisation.

In the light of more recent researches on the magnetic induction in closed circuits the same conclusion is arrived at, for if the magnetic induction B has been carried to an equal degree in the metal, the tension in degrees per square centimetre at any point of the circuit is

$$T=\frac{B^2}{8\pi}$$

and the element of pull over the area dA is

$$dP=TdA=\frac{1}{8\pi}B^2dA$$

so that

$$P=\frac{1}{8\pi}\int B^2dA$$

which can be determined if the law of distribution of magnetic induction through the cross section is known. Assuming this to be uniform, we have

$$P=\frac{1}{8\pi}B^2A.$$

This formula gives a convenient method of determining B from measurements made of the pull on a given polar surface, the formulæ becoming

$$B=5000\sqrt{\frac{P\text{ kilos.}}{A\text{ sq. cm.}}}$$

$$B=1317\sqrt{\frac{P\text{ lbs.}}{A\text{ sq. in.}}}$$

The a of Haecker's formula may therefore be considered to be simply proportional to the square of the magnetic induction through the surface of contact, or

$$a=\frac{1}{8\pi}B^2d^3c$$

where d is the density of the steel, and c the ratio of the polar surface to that of the face of a cube of volume equal to that of the magnet. According to Haecker, a is twice as great for a horseshoe magnet as for a bar magnet; according to Van der Willigen, three or four times as great, showing that in the former case, owing to the great resistance offered by the long return path through air of the tubes of magnetic induction, the steel magnet was only able to produce a much smaller induction (in the ratio 1 to $\sqrt{2}$, according to Haecker's results) than when the circuit was closed. The lifting power being proportional to surface, with a given intensity of magnetic induction, explains the greater lifting power of small magnets in proportion to their weight, without assuming, as is often done, that small pieces of steel can be more highly magnetised than large ones.

In electromagnets a simplification is introduced by the principle of the magnetic circuit. Assuming the material of the core and armature to be similar in permeability and cross section, B is independent of the value of the latter, and is given by the formula

$$B=\frac{4\pi S i \mu}{10 l}$$

where μ is the permeability, l the total length of the magnetic circuit, i the current in ampères, and S the number of convolutions in the coil. For values of B between 6000 and 16,000 μ is approximately given by the formula

$$\mu=\frac{16{,}000-B}{3{\cdot}2}$$

which gives for the approximate lifting power of such an electromagnet

$$P \text{ kilos.}=A \text{ sq. cm.}\times\left(\frac{3{\cdot}2Si}{Si+2{\cdot}56l \text{ cm.}}\right)^2$$

or

$$P \text{ lbs.}=A \text{ sq. in.}\times\left(\frac{12{\cdot}2Si}{Si+6{\cdot}5l \text{ in.}}\right)^2$$

THE SOCIETY OF TELEGRAPH ENGINEERS AND ELECTRICIANS.

At the meeting of this Society, held on the 24th ult., Sir William Thomson exhibited and described his standard balance and some other electrical measuring instruments, of which an illustrated account has already been given in the present volume of *Industries*, page 93. We shall, therefore, limit ourselves to the description of improvements in the details of construction which have since then been introduced. The marine voltmeter, consisting of a small oblate of soft iron in the centre of a solenoid of fine copper wire and supported on a platinoid wire stretched by a spring of the same material, and of a form resembling a coach spring, but without the friction joints of the latter, was originally constructed with a latent zero. The reason for this was that in the case of all the materials which had been tried for the supporting wire previously to the use of platinoid, the elastic retentiveness of the wire had caused "creeping" to take place for some time after the current had been sent through the instrument. Sir William, however, found that with platinoid wire there is no appreciable elastic retentiveness, and the needle can be allowed to return to zero, because, after a year's experience with the instrument, he found that the variation does not exceed one-fifth per cent. The instrument is now being constructed with a visible zero. He pointed out, moreover, that if any "creeping" should be found to take place, the instrument might easily be converted into one with a latent zero by the use of a movable stop which could be removed when it was desired to verify the zero. The original form of instrument was not available for use over a large range, as there was found to be a difference in the readings when the current was reversed, due partly to earth induction and partly to a small amount of retained magnetism. With the instrument as now constructed the difference in reading on reversal is found to be less than one-tenth per cent. with a range of 90 to 120 volts. The instrument is now supplied with a commutator by which its accuracy on reversal can be tested, and if there is any trace of retained magnetism it can be easily eliminated by rapidly turning the handle of the commutator for a short time, and so producing a series of rapid reversals in the current. It was stated that the instrument had been practically tested by being used on four or five voyages across the Atlantic, and had been found perfectly satisfactory. In the standard balance instruments intended for use with alternate currents, the base and the core of the coils were made of slate instead of copper, and a number of these instruments had been supplied for use at the Grosvenor Gallery installation. With reference to their adaptability for rough usage, it was stated that an instrument which had been damaged at a Belgian Custom House, and in which the lever had actually been bent, had been returned to the maker to have the lever straightened. After repair, this instrument was tested in Sir William's laboratory, and its variation was found to be only about one-twentieth per cent., a result due to the fact that according to the design of the instruments the working range is always in the neighbourhood of the minimum value of the force, and a small variation in the length of the ligament or centre of suspension has no appreciable effect on the calibration. Owing to the difficulty experienced in getting thick copper rings forged with accuracy, the fixed rings of the large current instruments, termed the hecto- and kilo-ampère balances, were made of a number of turns of tinned copper ribbon, wound in the proper shape, and then soldered together by heating the ring.

The indications of the original form of the direct reading vertical scale voltmeter, usually known as the "engine room voltmeter," in which one fixed and one movable coil were used, were found to vary slightly with the hygroscopic condition of the air owing to absorption of moisture in the movable coil, and it was necessary to test the instrument each time it was used, especially if it had been out of use for a few days, by stopping the current and removing the weight, and then observing whether the movable coil came to rest in the zero position. This was very inconvenient, and has been remedied by the use of two fixed pairs of coils. The variation of weight due to moisture in the two movable coils has no effect, as the coils are on opposite ends of the balance beam. The temperature correction is now made with great accuracy by simply setting a small flag on the balance to the number indicated by a thermometer attached to the instrument.

After the close of the description of these instruments, samples of which were exhibited, Mr. Preece alluded in complimentary terms to the great value of the different electrical measuring instruments designed by Sir William Thomson, and pointed out that electricians were entirely indebted to him and to Dr. Werner von Siemens, who was present at the meeting, for the introduction of instruments of precision for the purposes of electrical measurement. He stated that a considerable experience with the instruments described, and also of Sir William Thomson's older forms of instruments, had convinced him that they were, without exception, absolutely reliable.

Professor Ayrton, after alluding to the great importance of electrical measuring instruments which would give accurate results, and expressing admiration for the great skill shown by Sir William Thomson in devising instruments for exact measurement in all branches of physics, stated that he and Professor Perry had experienced difficulty in the use of platinoid springs, owing to their becoming oxidised and so undergoing changes in elasticity.

Professor Forbes, referring to an instrument among those exhibited, but which had not been alluded to in the present communication, mentioned that he had pointed out that a water tube used to prevent short circuiting when connecting the instrument with high potential mains would not work with alternate currents, and inquired whether Sir William Thomson had succeeded in getting over the difficulty.

Professor Fleming stated that he had used a standard balance almost daily for the last two years, and had found it absolutely reliable. A small standard balance instrument for currents ranging from a small fraction of an ampère to 3 ampères, he had found most useful for calibrating graded galvanometers in the lamp factory. The galvanometers were connected up in a single series every morning at 10 o'clock, and a current of 1 ampère, measured by Sir William's instrument, was sent through them, when each workman adjusted his instrument for the day. He stated that though the instruments looked somewhat complex, observations could be made with them in even less time than with a tangent galvanometer.

Mr. Swinburne pointed out that the Deprès d'Arsonval galvanometer, now so extensively used in France, and which was extremely dead beat, was simply one of Sir William's syphon recorders inverted.

Mr. Granville inquired whether the instruments, working with feebly saturated iron, would not be liable to error from vibration, as with feeble currents the magnetisation of iron was greatly facilitated by vibration.

Sir William Thomson, in replying to these questions, stated that in his experience platinoid was not liable to oxidation, and he had used a platinoid spring on a deep sea sounding apparatus, and though sea water was allowed to dry on it daily, no oxidation or change of elasticity was observed. Different specimens, however, varied greatly, and even specimens of the same wire showed great variation both in resistance and in the value of the temperature co-efficient. As platinoid was a substance which had only been recently manufactured, he thought this was due to defects in the process of manufacture, and suggested that the subject was well worthy the attention of physicists and chemists, owing to the great value of platinoid for electrical purposes. He was much indebted to Professor Forbes for his observation with regard to the water tube, and thought the explanation he had suggested the right one—viz., that the water was not electrified with sufficient rapidity to change the plates in time, and therefore the value of the potential obtained was not the true mean value. He had on this account abandoned the use of the water tube for alternate currents, and substituted a wire. With regard to the effect of vibration on the magnetisation of iron, he pointed out that more than thirty years ago Flinders had suggested for the correction of the compass the use of a soft iron bar, the magnetism of which would be reversed when that of the ship was reversed, as would be the case on crossing into the southern hemisphere. It was, however, found unsatisfactory, on account of its liability to sudden changes of magnetism from accidental jars. In experimenting on the subject, he had found that while this was the case with long thin bars, it was not so when the length of the bar did not exceed eight or ten times its diameter, and such a bar might be mounted near the compass needle, and then receive a blow from a mallet without any effect being produced on the needle. He had applied the same principle to the instruments in which feebly magnetised soft iron was used, employing an oblate with the equatorial diameter about double of the polar diameter, and he had then found no difficulty from vibration.

Books Received.

Journal of the American Chemical Society. Vol. IX., Nos. 6 to 10.

A Treatise on Mathematical Instruments. By J. F. Heather, M.A. Revised, with additions by Arthur T. Walmisley, M.Inst.C.E. 14th Edition. London: Crosby Lockwood & Son.

The Watch Makers' Hand Book. Translated from the French of Claudius Saumei, and considerably enlarged, by Julien Tripplin, F.R.A.S., and Edward Rigg, M.A. London: Crosby Lockwood & Son.

Cassell's Technical Educator. New and Revised Edition. Part I. London: Cassell & Co., Limited.

Wealth and Progress. By George Gunton. London: Macmillan & Co.

The Testing of Materials of Construction. By William Cawthorne Unwin, F.R.S., M.Inst.C.E. London: Longmans, Green, & Co.

Allan Glen's School and Technical Education. An address by George G. Ramsay, M.A., LL.D. Delivered at the distribution of Science and Art Department prizes and certificates to the pupils of Allan Glen's School, 22nd December, 1887.

A Pocket Book of Electrical Rules and Tables for Electricians and Engineers. By John Munro, C.E., and Andrew Jamieson, M.Inst.C.E. Fifth Edition, Revised. London: Chas. Griffin & Co.

Reports from the Consuls of the United States: Bimetallism in Europe. No. 87. December, 1887. Washington: Government Printing Office.

Counsel's Retainers. By E. B. G. London: William Clowes & Sons, Limited.

The Cornell University Register, 1887-88. Ithaca, N.Y.

Transactions of the Institution of Engineers and Shipbuilders in Scotland. Meeting, 21st February, 1888.

Hand Book of Brewing Calculations. By O. W. Villiers. London: Sheppard & St. John.

The Vosburg Tunnel: Description of its Construction. By Leo von Rosenberg, 35, Broadway, New York.

Transactions of the North-East Coast Institution of Engineers and Shipbuilders. Meetings, 11th January, 1888, and 8th February, 1888.

A National Canal between the Four Rivers a National Necessity. By Samuel Lloyd. London: James Hogg and Sons.

Factory Accounts: Their Principles and Practice. Second Edition. By Emile Garcke and J. M. Fells. London: Crosby Lockwood & Son.

The Increase in the Produce of the Soil through the Rational Use of Nitrogenous Manure. By Professor Paul Wagner, Ph.D. Translated by George G. Henderson, M.A., B.Sc. London: Whittaker & Co.

The Proceedings of the Bimetallic Conference held at Manchester, 4th and 5th April, 1888. Published by the Bimetallic League, 5, Cross-street, Manchester.

The Rothamsted Experiments on the Growth of Wheat, Barley, and the Mixed Herbage of Grass Land. By William Fream, B.Sc. Lond., F.L.S., F.G.S., F.S.S. London: Horace Cox, *The Field* Office.

Reviews.

On a Surf Bound Coast, or Cable Laying in the African Tropics. By A. P. Crouch. London: Sampson Low, Marston, Searle, & Rivington.

"This book," as the preface states, "forms a portion of a diary kept during a cable laying expedition down the West Coast of Africa, commencing at the English settlement of Bathurst, on the River Gambia, 13° north of the equator, and terminating at the Portuguese town of St. Paul de Loanda, 8° south of it." The whole expedition occupied six months; but in this volume the author only treats of the first half of his travels, reserving, as he informs us, the publication of the remainder until he can estimate public encouragement of this class of literature. The reception of books of travel in this country is fortunately not uncertain, and we doubt not that Mr. Crouch's volume will find not a few appreciative readers. Many of his sketches of shipboard scenes and of places visited during the cruises are well drawn and true to life; but his sea experience has evidently been rather limited, and the range of his observation narrow, or so many very trivial entries in his diary would not have found their

Digitized by Google

way into print. Again, his style is somewhat juvenile, for almost the only trace of that "go" which is usually associated with travel, is to be found in the title of the book. The author on the title page is Mr. Crouch; in his diary, however, he assumes the name of Bertram, and also bestows fictitious names on his ships and shipmates. We cannot see the necessity of so doing, as the author is not, or is not supposed to be, romancing. Perhaps there is no class of travellers who possess more ample facilities for observation than telegraph cable engineers; splendidly equipped, as they are, with scientific apparatus, and enjoying ample leisure, we are justified in expecting from them new light on some of the many branches of science which may be so enriched by extended observational research. Travel is common now, and probably the readers are growing fewer who are inclined to absorb pages of mess room gossip; but there is an ever increasing class to whom the traveller by sea or land may confidently appeal with fresh and vigorous descriptions and thoughts of distant men and countries, or new glimpses into the wonders of the ocean.

Labour Statistics: Returns of Wages published between 1830 and 1886. Parliamentary Blue Book C.—5172. 4s. 8d.

Statistics of wages are of so vast importance to the industrial community, that few will grudge the modest sum which is now voted for the office of Labour Correspondent and for the preparation and publication of blue books of labour statistics; but the public interest demands that such sums should be usefully spent, and those who wish to have the new Labour Bureau efficiently conducted ought to be most anxious in their insistence that none of the moderate sums devoted for its service should be fruitlessly expended. The bulky Blue Book which has recently been published is a compilation of figures about wages made from the periodical publications of the Board of Trade during the past fifty years. Even had these figures originally possessed any statistical value, their re-publication might have been objected to on the ground of its involving unnecessary expense; but since from first to last these figures are utterly void of significance as labour statistics, their re-publication is an unmitigated absurdity. The note by Mr. Giffen, which prefaces the tables, states that they have been based mainly upon returns obtained by circular from chambers of commerce throughout the country. They are, therefore, not official but distinctly amateur returns, made up without uniformity of method and with inevitably varying degrees of inaccuracy. The figures as they stand afford absolutely no basis for inductions as to wages movements during the past fifty years. The possibility of irregularity of employment affecting the result is scarcely hinted at, and in many cases the approximations are so wide (35s. to 50s. *e.g.*) that there is no possibility of drawing any conclusions from them. The volume before us consists of two parts; the first containing returns of wages in some dozen industries between 1832 and 1853, though in a few cases they date back to 1810, and the second containing returns of wages from 1855 till 1886. A third part is promised, the work upon which is described as "most laborious," and as involving considerable time to complete. This part will contain reprints of miscellaneous statements, which have appeared in Parliamentary papers and in the reports of Royal Commissions. It will also contain an attempted comparison of the figures as given in the two earlier parts. Part III. will, therefore, probably be of more importance than Parts I. and II., although its value may be largely discounted, so far as any of the conclusions it may contain are based on the figures published. Statistical science has on the Continent and in America, at all events, reached a much higher level than the mere huddling together, without rational arrangement, of sets of figures destitute of authority and destitute of value, even if they were authoritative. The Labour Bureau might do good work both of a practical and of a scientific order; but the three volumes which so far have been published during nearly two years of its existence, are simply a frittering away of public money. It is worth while for those who interested themselves in Parliament in the establishment of the Labour Bureau, to consider the advisability of its re-organisation with a staff of competent statisticians, or its abolition. As it is at present it is utterly useless for any purpose, whether practical or scientific.

The American Journal of Mathematics. Vol. IX. Nos. 3 and 4, 1887. Baltimore: Publication Agency of the Johns Hopkins University.

The eight volumes of the "American Journal of Mathematics" that have already been published are well known to mathematicians as containing original work in the field of pure mathematics of the very highest order, and the two numbers of the ninth volume that lie before us maintain the standard of previous issues. The form of the Journal, apart from its contents, is worthy of notice; its wide pages are admirably adapted for the lengthened formulæ of modern analysis, and compare favourably with the narrow pages of most English journals, in which it is frequently necessary to print the formulæ of a memoir so as to read from top to bottom instead of from side to side. Number 3 opens with a paper by Professor Cayley "On the Transformation of Elliptic Functions." In the earlier articles he makes a comparison of what may be called the $Mk\lambda$- and the $\rho\alpha\beta$-forms, discusses the connection of the $Mk\lambda$- and the $\rho\alpha\beta$-theories, and deals with the modular and multiplier equations. He then takes up the development of y in the form $y=\rho x\,(1+\pi_1 x^2+\pi_2 x^4+\ldots)$ where π_1, π_2, &c., are functions of ρ, α, β, and in connection with this theory considers the solutions of the problem of transformation given by Jacobi's partial differential equation, and by the Jacobi-Brioschi differential equations, and also develops the theory contained in his own memoir (in the Phil. Trans.) on the "Transformation of Elliptic Functions." The present memoir is an interesting one; but like most of Professor Cayley's papers requires a good deal of work to follow it thoroughly. "Forms, Necessary and Sufficient, of the Roots of Pure Uni-Serial Abelian Equations" is the subject of a very able memoir by Mr. G. Panton Young. He applies the term "uni-serial" to an abelian equation when the roots form a single circulating series. An idea as to the contents of the paper will best be given in Mr. Young's own words: "First, a criterion of pure uni-serial abelianism is established. A deduction is then given of the necessary and sufficient forms of the roots of pure uni-serial abelian equations of all prime degrees. Then the necessary and sufficient forms of the roots of the pure uni-serial abelian quartic are obtained by two different methods. Then the necessary and sufficient forms of the roots of the pure uni-serial abelian of a degree which is the continued product of any number of distinct prime numbers are found. Then the problem is solved for the pure uni-serial abelian of a degree which is four times the continued product of any number of distinct odd primes. Finally, from the relation between the solvable irreducible equation of prime degree n and the pure uni-serial abelian equation of degree $n-1$, the necessary and sufficient forms of the roots of the irreducible solvable equation of prime degree n are shown to be determinable for all cases in which $n-1$ is either the continued product of a number of distinct primes, or four times the continued product of a number of distinct odd primes." The memoir forms a substantial contribution to the theory of abelian equations. A table of the "Symmetric Functions of the 14ic," by Mr. W. P. Durfee, concludes the number.

In the second of the two numbers before us, the most important article consists of Lectures XXV.—XXXII. of Professor Sylvester's "Lectures on the Theory of Reciprocants." Mr. Hammond, who reports these lectures for the Journal, is, as might be expected from such a skilled algebraist, not merely a reporter; to him exclusively is due, as stated by Professor Sylvester, an important proof in Lecture XXIX. These lectures, the conclusion of which is promised for a subsequent number, will not be the least valuable of the numerous contributions their eminent author has made to the development of the more difficult branches of analysis. "Sur une Classe de Nombres remarquables" is the title of an article by M. Maurice d'Ocagne. The article is a study of certain numbers which have been met with by previous writers, but not systematically discussed. In addition to systematising known results, M. d'Ocagne gives some that are both new and interesting. His formula, numbered (42), is noteworthy. In a letter addressed to the associate editor of the Journal, M. Hermite, the distinguished French *savant*, communicates *inter alia* a treatment of the "Fourier Formula," which is, we believe, new to English readers; though M. Hermite intimates that the results had been previously obtained in a different way by the German mathematician Lipschitz. This is but one of many instances in which different investigators have independently reached the same results; yet the feelings supposed to be cherished towards those "*qui ante nos nostra dixerunt*" may often be pleasurably modified by the consideration that in mathematics methods are equally important with results. The latter part of the extracts from M. Hermite's letter is remarkable for the reconciliation of two apparently conflicting developments of the cosine in a product of primary factors analogous to that given by Weierstrass for the sine. The concluding paper of the number contains two proofs of Cauchy's theorem, "that $\int_1^2 wdz$ has the same value for any two paths joining the points 1 and 2, if w be a uniform and continuous function of the complex variable z throughout the area included between those paths" by Mr. F. Franklin. Both proofs are simple; the second, in particular, is extremely neat; the wonder is that it has not previously been given.

To mathematicians, the two numbers we have thus briefly noticed are full of interesting reading, and they will take a fitting place alongside their predecessors.

WATER GAS AS USED FOR METALLURGICAL PURPOSES.*

Some years ago a paper was submitted to this Institute on apparatus for making water gas by Messrs. Lowe & Strong. Since then, however, great improvements have been effected, principally by German engineers, so that the plant is now extremely simple and durable. Before entering upon the construction of the improved apparatus which is now used in Europe in the generation of water gas, a pause may be made to consider the reactions which are involved in passing steam through a mass of incandescent carbon. Steam, in passing through red hot carbon, produces a mixture of carbonic acid, carbonic oxide, and hydrogen, in which mixture the proportion of carbonic acid varies according to the temperature of the mass of heated carbon when the steam is passing through it. If this temperature is high enough, there is no carbonic acid produced at all, only carbonic oxide and hydrogen, so that the water gas which is obtained is composed theoretically as under:—

By volume.	By weight.
CO, 50 per cent.	94 per cent.
H, 50 per cent.	6 per cent.

As the temperature decreases, the proportion of carbonic acid increases, whilst the proportion of carbonic oxide in like manner decreases, so that finally the result would be the production of a gas composed as under:—

By volume.	By weight.
CO_2, 33 per cent.	92 per cent.
H, 66 per cent.	8 per cent.

Carbonic acid passed through carbon begins to be decomposed into carbonic oxide at a temperature of 550°C.; and at a temperature of 950°C. the production of oxide rises to 94 per cent., while at 1000°C. the transformation is completely obtained. Similar results are realised on passing steam through incandescent coke; at a temperature of 500°C. its decomposition to hydrogen and carbonic acid is complete. From 1000°C. to 1200°C. the carbonic acid is converted into carbonic oxide. The whole reaction is, therefore, as follows: The decomposition of steam produces hydrogen and carbonic acid, and by continued contact with the incandescent coke, the carbonic acid is transformed into carbonic oxide. It may be stated that a cubic metre of water gas develops in round numbers 3000 cals. Theoretically, the temperature produced is 2839°C. Combustion of the carbonic oxide to carbonic acid causes 3021 cals., that of the hydrogen 2649 cals. The first figure, therefore, constitutes a mean between the others. In regard to this, it may be mentioned that the figures given for the first and the third of these temperatures are evidently exaggerated. This slight inaccuracy must be attributed to the supposition that, whilst at these high temperatures, the specific heat remains constant in the case of steam, as in the case of carbonic oxide; but this cannot be the case, at least as far as steam is concerned, seeing that the experiments of MM. Langen and Mayer have proved that with this vapour dissociation commences at 1200°C., whilst with carbonic oxide no change is perceptible even at a temperature of 1690°C. A word should be said about a reaction which occurs also in the manufacture of water gas, viz., that of carbonic oxide on steam. In heating a mixture of carbonic oxide and steam, a reaction is set up (according to the experiments of Professors Nauman and Pistor) on carbonic oxide, which begins at a temperature of about 600°C., and produces carbonic acid and hydrogen. With an augmented temperature this reaction increases, so that at 900°C. there is produced 10 per cent. of carbonic acid. According to experiments made at Essen in the water gas generator, where ordinary steam was replaced by a mixture of water gas and steam, and the mixture then passed through the generator at a high temperature, the whole of the carbonic oxide contained in the water gas was finally reduced to carbonic acid. As one kilo. of oxygen, in reducing carbonic oxide to carbonic acid, gives more heat than when it is employed with hydrogen to form water, the operation which we have described is accompanied by an evolution of heat. It will now be seen how these facts, derived from experiments, can be practically utilised. In all water gas apparatus the principal part consists of a generator, in which the fuel, by the aid of an air blast, is raised to a high temperature, to be afterwards cooled by a jet of steam for the production of water gas. During the heating up by means of the blower, Siemens or generator gas is produced, whilst the cooling effected by the steam produces water gas. The characteristic, therefore, of the water gas generator consists in producing alternately Siemens gas and water gas. According to the use which it is desired to make of the Siemens gas, the fuel which is used, and the manner of passing the steam or passing the air, or *vice versâ*, there has arisen a combination of apparatus of different construction. A description will be given of one amongst these. At the beginning of the operation the gas is entirely free from carbonic acid and steam. In proportion as the mass of combustible is cooled, the gas acquires a larger quantity of one or the other. The passage of 1100 litres of gas into a condenser yields 24cm. of water, which is equivalent to 4 per cent. by weight. The fuel employed by preference in Germany is the small coke easily obtained from the residue of the fires of puddling or heating furnaces, or coke obtained directly from coke ovens or gas works. In any case, the percentage of sh varies from 10 per cent to 30 per cent.: frequently it is from per cent. to 20 per cent. It is desirable, then, to construct the s erating apparatus in a form from which large quantities of c ers may be easily withdrawn, and to make it durable. Thi problem has been resolved by the adoption, in the lower part of the generator, of a water ring, which obviates the use of a grate, and protects that part most exposed to heat and to destruction by the slag. This water ring is arranged so that beneath it there is an open annular space, round which the air enters during the blowing operation. It is also by this that the water gas escapes which is produced by the next process. The slag is thus deposited on the conical surface of the fuel, in a covering which extends up to the opening of the water ring, and the cinders may be easily withdrawn by means of four cleaning doors. The cleaning out

* A paper read by Mr. A. Wilson, before the Iron and Steel Institute, on May 9th, 1888.

Digitized by Google

is done every six hours, and occupies from fifteen to thirty minutes, according to the quantity of cinder produced. In blowing in the air, the cold blast arrives against the surface of the lower part of the ring and cools it, and so carries away the radiant heat thrown off at the bottom. This radiant heat, further, only exists, or has no importance, except just after cleaning, when the slags which have been deposited have been removed. The almost immediate formation of a new layer of cinder or slag then prevents much loss by radiation. The matter is different during the operation of gas making; the water gas escaping at a temperature of from 1200°C. to 1500°C., imparts its heat to the lower part of the water ring, and this is carried off by the cooling water; but this quantity of heat would in any case be lost, seeing that it must be disposed of before the entrance of the gas into the gas holder. It matters little, therefore, whether this abstraction is commenced by the water ring or whether it is effected entirely in the scrubber. The first water gas plant successfully put to work for practical use in Europe was erected by Messrs. Schulz, Knaudt, & Co., at Essen, and consisted of two generators, each capable of producing 10,000ft. of water gas per hour. These generators are about 6ft. 6in. external diameter by 18ft. high. The gas, on leaving the scrubber, passes by a cast iron pipe to a gas holder of about 40ft. diam., and situated about fifty yards from the generator house. From this holder the gas is led away by mains to the various welding furnaces; and another portion is taken from the holder expressly for lighting purposes, and this portion only is passed through the purifier to remove carbonic acid and sulphur compounds. The generation of the gas is so rapid, that when the steam is passed into the fuel, the holder rises some feet at one operation, and may easily be observed to be rapidly ascending. As to the other details of the apparatus which is at work at Essen, in the works of Messrs. Schulz, Knaudt, & Co., it should be stated that

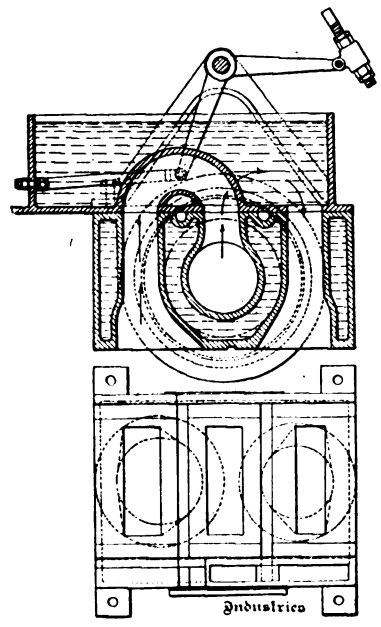

Fig. 1.

it was constructed on the system of Strong's patent, at least so far as concerns the employment of a double regenerator, heated by the hot gas which escapes when the air is blown in, intended to superheat the steam serving for the production of water gas; and this steam did not pass through the incandescent mass of coke except in a superheated state. In working the apparatus it was soon found that the complete combustion of the Siemens gas had a tendency to cause a rapid destruction of the bricks in the regenerator, and this not only on account of the very high temperature, but also on account of the cindery dust—the combustible containing as much as 25 per cent. of ash. When this was ascertained, the top supply of air to the regenerator was stopped, and the regenerator chambers were only heated by the sensible heat in the Siemens gas; that is to say, to a temperature of about 500°C. In consequence of this, the steam was not highly superheated, but the consumption of fuel did not increase in the proportion which had been feared; further, the yield of the apparatus increased to a notable degree, because the quantity of air furnished by the blower, instead of being divided into two parts, for the top supply and the bottom supply, was entirely utilised for the latter, and the heating up did not require more than half the time previously employed. This had the effect of doubling the production of water gas, *i.e.*, a production which at first not being more than 120cm. per hour, rose to from 250cm. to 300cm. per hour, without any sensible increase in the consumption of fuel. After being transformed to gas by the action of the fuel, of which the lowest part is heated to whiteness, whilst the upper part is of a dull red, the steam passes by way of the first named portion through a hydraulic lute communicating with a coke scrubber. Cooled in this manner, the gas enters the gas holder. In order to prevent any danger of the blast passing by leakage along with the gas, an ingenious and highly successful slide valve was introduced by Mr. Blass, of Essen. The construction of this is indicated on diagram Fig. 1, by which it will be observed to consist of a D valve, sliding on three ports, and provided with an open water trough to keep it cool; whilst in the face of the valve between the ports grooves are cut, so that any leakage of air or gas respectively must pass to the atmosphere instead of forming mixtures in the pipes, which might prove dangerous. When once the charge is heated up, the steam is admitted for the production of water gas for about five minutes, when the valves are reversed simultaneously, and the charge is blown up to restore heat during about ten minutes, the various movements of the apparatus being all controlled in a convenient manner by one lever or hand wheel. Owing to this construction the generator is converted into a machine, and for three years its mechanism has worked with perfect regularity, whilst the repairs needed by the brick lining have been of a most trifling description. Employing ten minutes for blowing up, and five minutes for the manufacture of water gas, each generator

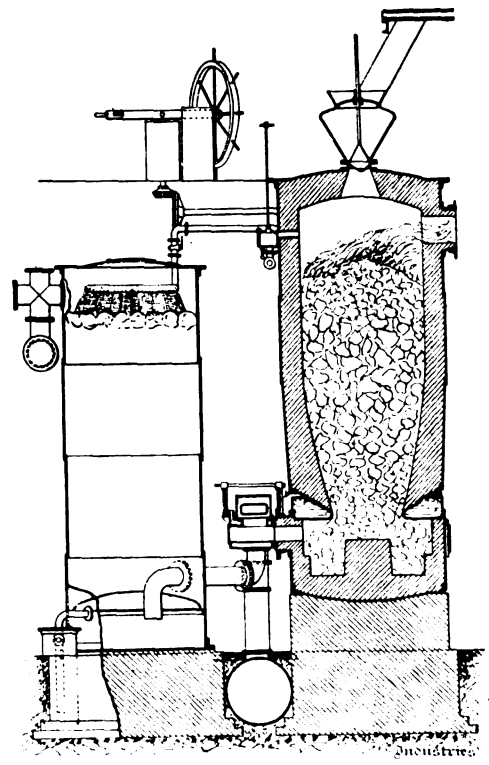

Fig. 2.

produces from 250 to 300 cub. m. per hour. The carbonic acid never exceeds 4 per cent., so that the final result is a gas composed of 5 per cent. nitrogen, 4 per cent. carbonic acid, 41 per cent. carbonic oxide, and 50 per cent. hydrogen. The next plant put to work was erected at the Witkowitz iron and steel works, in Austria, and consisted at first of two generators, each capable of making 20,000ft. of water gas per hour (the construction of these is indicated by Figs. 2 and 3), also the necessary scrubber and gas holder. In this case the water gas is used for driving

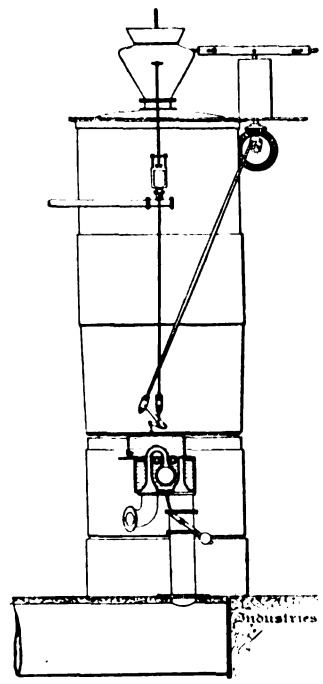

Fig. 3.

open hearth steel melting furnaces, and for lighting the works on the incandescent system, which will be shortly described, whilst the generator gas is used for firing the boilers. As regards the construction of the steel melting furnaces, it may be observed that only two regenerator chambers, instead of four, are employed, and this arrangement tends to simplify the construction of the furnace, and reduce the wear and tear and first cost. With only one pair of regenerators, which are used for heating the air, the temperature is so high that very great rapidity is attained in working, no less than five charges being got out in twenty-four hours, with a proportion of scrap of less than one-third. Five hundred cubic metres (=17,655 cub. ft.) of water gas is used per ton of ingots; and the manager, Mr. J. Langer, expresses himself as convinced that there is a great advantage in using water gas for steel melting, always provided that the generator gas which is produced at the same time is employed for boiler firing or similar purposes. There is no doubt that, if the furnaces were of a larger size, such as are generally used in this country, say, working from ten to twenty ton charges, the consumption would be very much smaller. Water gas is also employed at Witkowitz for heating the billet furnaces, the consumption being 270 cub. m. (= 10,000 cub. ft.) per ton of steel billets rolled. At Witkowitz the fuel used is small coke, and the water gas produced amounts to about 33,000 cub. ft. per ton of fuel, along with about 130,000 cub. ft. of generator gas, which, as before mentioned, is used for firing boilers. At Hoerde, a very extensive water gas plant has been erected by Mr. Massenez, who intends to use the water gas generally for melting and heating, also for lighting the works, and the generator gas for boiler firing. A similar plant has been erected by Mr. Sampson Fox, at the Leeds Forge Company's works, for welding flues and illuminating. A smaller generator, for the production of about 2000ft. of water gas per hour, is shown in Fig. 4. As this is designed particularly for lighting purposes, the greatest simplicity was aimed at in its design. The draught is obtained by a small steam jet exhauster sucking out at the top, and this combination possesses the following advantages: During the blowing up it is impossible for the air to pass the hydraulic seal and escape to the gas holder, this seal being sufficiently heavy to resist the suction without materially augmenting the back pressure during the manufacture of gas; the suction also allows of the extraction of ashes during the heating up without work being stopped. The small opening through which the charging is done serves alternately for the chimney. A plate, provided with three openings radiating from a pivot, is turned by means of a hand wheel into three given positions. In the first there is a chimney provided with the aspirator, in the second there is a charging hopper, and in the third there is a cover plate. To work the apparatus, therefore, the attendant has nothing to do but to turn his wheel to right or to left during intervals which are exactly determined by experience, or, more particularly, by analysis. This apparatus consumes 3lb. of coke, containing 14 per cent. of ash and 5 per cent. of water, in making 35 cub. ft. of gas. There is included in this figure such coke as is uselessly

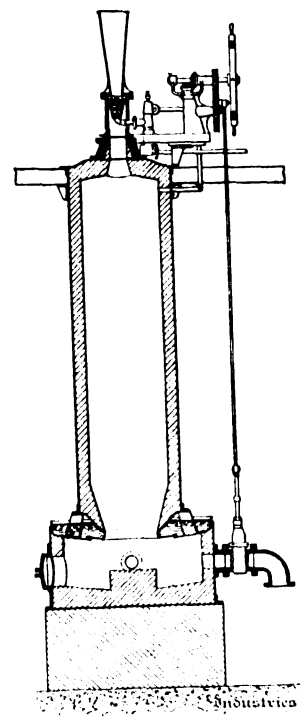

Fig. 4.

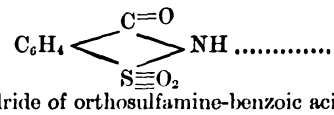
consumed during the night. The blowing up is continued ten minutes, after which the manufacture of gas occupies five minutes; the quantity of water used by the water cooling ring is about 750 gallons per day of twenty-four hours. It should also be mentioned that the water runs during the night as well as when the gas is being made. The first generator of this size was erected by Mr. Pintch, whose name is well known in connection with railway carriage lighting, and it is used for illuminating his works at Furstenwald, near Berlin, as well as the railway station adjoining, with all the signal lamps, &c. Another of the same size has been erected by the author at Stafford, and may be seen at work at any time. It should also be mentioned that water gas plants are successfully at work at the Terni Steel Works in Italy, and in the engineering shops of Messrs. Sulzer Brothers, Winterthur, Switzerland. Water gas is made in America almost exclusively for lighting by carburation. In Europe this has not been practised, partly on account of the price of petroleum refuse. In the first apparatus constructed in Germany there was no object in view but the production of heating gas for metallurgical work, or that which limited its employment to heating and melting purposes. It was then found that the water gas burnt without an excess of air, and produced so high a temperature that a platinum wire was melted by being placed in the open flame; this corresponds to a temperature of 1700°C.—the highest temperature recorded by Rosetti with a Bunsen burner using coal gas being only 1350° ("Annual Report of Chemical Technology, 1887"), a heat which does not approach that of water gas. According to the experiments of Aime Witz ("Annals of Chemistry and Physics"), lighting gas only develops 4000 cals. to 5000 cals. instead of 6000 cals., as before supposed. It accrues from this, that this gas, owing to the rapidity of its combustion, has a reduced flame area, and consequently is less cooled on the surface by radiation. A flame of ordinary gas, with the same speed of consumption, possesses a surface six times as large as the water

Digitized by Google

gas flame; and although a cubic metre of lighting gas produces theoretically double the heat by its combustion, the temperature of the flame is at the same time much less. Thus, in a small trial furnace, Bessemer steel was easily melted by water gas and cold air, and poured out in a perfectly fluid state. But the best proof which it is possible to have of the high temperature of water gas is found in the incandescent magnesia light on Fahnejelm's system. This constitutes the very best system of gas lighting by incandescence, and it may be described as follows: The flame heats a comb, composed of little magnesia rods, to whiteness, producing a light superior to the incandescent electric light, but without having the bluish tinge of the arc lamp, and consequently resembling more nearly the splendour of sunshine than any other existing system of lighting. This light possesses, besides, the advantage of absolute steadiness. This follows from the circumstance of having a certain mass of matter in an incandescent state, requiring an appreciable time to cool it and to effect a variation in the power of the light, and consequently preventing any irregularity in the luminosity of the flame. In order to obtain the same quantity of light by this system, it is necessary to consume the same quantity of gas as of coal gas. With a consumption of 150 litres per hour (=5·3 cub. ft.), a magnesia comb gives at first a photometric power of from 20 to 22 candles; after fifty hours it gives but 15 candles; and after one hundred hours only 10. The combs cost 1½d. each, so that their consumption amounts to about one farthing per hour, and per cubic metre of gas consumed the price amounts to one pfenning (1·25 centimes), equal to 2¾d. per 1000 cub. ft. The magnesia comb is supported by a wire, slipped into a socket on the carrier of an ordinary gas bracket. The burners used are exactly the same as those used for town gas, and so are the globes and all the fittings concerned. In substituting lighting by incandescence with water gas, therefore, no changes whatever are necessary in the existing pipes and gas fittings. The magnesia combs, being quite loose, may be removed and replaced in a moment. As before mentioned, this system of lighting has been adopted with great success at several large works on the Continent, and it is also largely used in America; and seeing that it offers a convenient and beautiful means of illuminating, possessing the convenience of town gas with the brilliancy of the electric light at less than half the cost of either, it must commend itself for adoption in this country also. On these grounds, it was thought by the author that some mention of this system of lighting in connection with this paper would be of interest to the members of the Institute, although perhaps the subject possesses the greatest importance to those present from a metallurgical standpoint. It may be well, before concluding, to revert shortly to the economic aspect of the question of the use of water gas in large quantities for steel melting and such purposes, as compared with the cost of the gaseous fuel at present generally used for the same purposes. The most approved and economical types of generator for making producer gas are worked by a mixture of air and steam, and make in reality a mixture of producer and water gas simultaneously. The water gas generators are alternately worked by air by itself to make producer gas, and then by steam by itself producing water gas; thus the same gases are ultimately produced by each system, but in the water gas plant they are separated. As the cost of the fuel and attendance is about the same in each case, as is also the loss of heat by external radiation, there can be no material difference in the value of the heating gases produced by either system, at a given cost for fuel and otherwise; thus in the manufacture of water gas, when this is averaged together with the producer gas necessarily generated in the operation, the cost of the water gas is, as demonstrated below, practically the same at that of the mixture known as generator or producer gas; and it cannot, therefore, be more expensive to use water gas for any operation than producer gas, when the value of the latter, also produced by the water gas plant, is credited, as it can be in any works where there are boilers, &c., to be fired. At the same time the separation of these gases, so as to have the water gas by itself, has very important collateral advantages and economies which are of great value. In the manufacture of water gas, if the water gas and the producer gas, also made separately, are subsequently mixed, the analysis of the mixture is substantially almost identical with producer gas made in the best and most economical manner, thus proving that the heating value of the gas made from the fuel is the same by each system, and the value received practically equal. Producer gas: One ton of slack coal, at 5s. 6d. per ton, yields of this gas about 150,000 cub. ft., equals per 1000 cub. ft., 0·44d., or slightly under one halfpenny per 1000. Water gas: One ton of inferior coke, at 6s. 3d. per ton, yields of this 35,000 cub. ft. of pure water gas, and about 140,000 cub. ft. of generator gas equals 175,000 cub. ft., equals per 1000 cub. ft. of the whole of the gas produced, 0·43d., or slightly under one halfpenny per 1000. The cost of steam raising and labour is the same in each system for the same analysis of mixed gases.



SACCHARINE, A NEW COAL TAR DERIVATIVE.

By Dr. Otto N. Witt.

Some two years ago, a new departure was made in the technology of coal tar derivatives by the production of an artificial sweetening stuff, called saccharine. This invention, made in the United States by a German chemist, Dr. Constantin Fahlberg, created an immense sensation when it was first published in 1886. As usual in such matters, the value of the invention was considerably exaggerated, and it is only now that we begin to have a somewhat clearer conception of its intrinsic merit.

Like all coal tar derivatives, saccharine belongs to the so-called aromatic series of organic substances. This series contains a very large number of useful substances, especially colouring matters and perfumes. Saccharine is the first among their number which claims a place amongst alimentary preparations. The fact that a compound of this series has a sweetening property is by no means so novel as has been supposed both by the public and by many scientific chemists. Those who are in the habit of working with aromatic compounds, know how exceedingly sweet many of them are. I remember very well a visit which I paid in the early spring of 1876 upon Dr. Peter Griess, the eminent chemist, of Burton-on-Trent. It was on that occasion that Dr. Griess demonstrated to me the excessive sweetness of baric orthonitrobenzoate, a comparatively common aromatic preparation; and I was in a position to reciprocate by explaining how, in the reduction of binitrobenzene, vapours of an extremely sweet taste were produced, and that the appearance of these sweet vapours was a reliable indication of a certain stage of the process having been reached. These two instances may suffice to show that saccharine is neither the first nor the only sweet compound among aromatic substances. It is, however, distinguished from its congeners by its apparent harmlessness. As far as has been ascertained hitherto, saccharine has no action whatever on the human organism. It is this peculiarity, comparatively rare amongst aromatic compounds, which qualifies saccharine as an admixture to human food. This virtue of saccharine is, however, also its fault. It does not injure our organism, but it has no nourishing properties whatever. For this reason saccharine is unable to do what at first was thought it would do in replacing sugar. The latter is not only sweet, but it has also strongly marked nourishing properties. Saccharine is only fit to tickle our palate; it is a mere luxury, a concession to our taste. Its proper use is, therefore, restricted to the comparatively few occasions where the sweetness of sugar is required without its nourishing properties—cases to be mentioned presently.

Before, however, entering into the details of the use of saccharine, I shall say a few words about its constitution, and the mode of its production. It has already been mentioned that orthonitrobenzoates are endowed with a remarkably sweet taste. Saccharine is also an ortho compound, and it is remarkable that its isomerides of the meta- and para- series are not sweet. For its manufacture this is a serious drawback. For, as we shall presently see, large quantities of the para- compound are formed together with the ortho derivative in an early stage of the process. The formation and consequent separation of this para-isomeride not only complicates the process of manufacture, but it also encumbers it with large quantities of a useless by-product. The constitution of saccharine is given by the following formula:—

(1)

it is the anhydride of orthosulfamine-benzoic acid. Only ortho compounds are capable of forming such anhydrides; parasulfamine-benzoic acid, for instance, exists in a free state, and cannot be induced to form such an anhydride. It is necessary to know this in order to understand one of the patented processes for the manufacture of saccharine. There is, chemically, only one way practically possible to obtain this interesting product. We start from toluene, a hydrocarbon which is largely prepared from crude benzole, and is now an article of commerce, in a state of perfect purity. Toluene is methyl benzene, and its transformation into saccharine is readily accomplished by a series of successive operations.

The first of these has for its object the introduction of the necessary sulpho group. It consists in treating toluene with sulphuric acid at a temperature below 100°C. This operation presents no practical difficulties whatever. It is strictly analogous to similar processes practised many years since in the manufacture of artificial dye stuffs. The acid is mixed with the toluene in a cast iron vessel, which is jacketed so that it may be heated by steam. A closely fitting lid prevents the hydrocarbon from evaporating, and a mechanical stirrer produces an intimate contact between the two ingredients. Gradually the toluene dissolves in the acid, and thus disappears entirely. When the operation is finished the contents of the vessel form a thick dark liquid which is readily soluble in water. In order to separate the toluene-sulphonic acids formed from the excess of sulphuric acid, quicklime is added. The calcic sulphate formed is insoluble, and may be separated from the solution of the calcium salts of the new sulpho acids by means of a filter press. The calcium salts are then transformed into the corresponding sodium salts by the addition of the necessary quantity of sodic carbonate. By renewed filtrations a solution is obtained, which, on being evaporated, yields sodic toluene-sulphonate in a state of purity. It is in this stage of the manufacture that the unwelcome formation of an isomeride takes place, which is not required, and the subsequent removal of which is both troublesome and costly. If the sodium salt, which is the outcome of this operation, be examined, it is found to consist of two isomerides belonging to the para- and ortho- series of benzene derivatives respectively. The ortho compound only is required, but its proportion never exceeds 50 per cent. of the mixture, whilst the useless para derivative is present in at least an equal quantity. It is not possible to separate these two isomerides by fractional crystallisation. The whole mixture has, therefore, to be subjected to a treatment forming the second stage of the manufacture. This second stage has for its object the production of the chlorides of the new sulpho acids. It is here that the manufacturer of saccharine encounters the greatest difficulties. One method only is known for the production of the chlorides of organic acids. It consists in treating these acids or their salts with phosphorus pentachloride. Now this latter substance is among the most unpleasant and dangerous ones to deal with. It is very volatile, and its vapours are most irritating. In order to avoid the use of this dangerous and disagreeable compound, the inventors work with phosphorus trichloride, which, although still dangerous and disagreeable in the extreme, is liquid, and therefore allows of more easy manipulation. According to the patent specification, the dry sodium toluene sulphonate is mixed in a finely powdered state with phosphorus trichloride, and a current of dry chlorine gas is introduced into the mixture. Earthenware or enamelled cast iron vessels are used in all probability for this operation. Phosphorus oxychloride is formed in the process. This is distilled off when a mixture of the two isomeric toluene sulpho chlorides with sodic chloride remains in the still. Of these two sulpho chlorides the para compound solidifies on cooling, whilst the ortho compound remains liquid. They can, therefore, be easily separated by filtration and pressure. The solid para compound forms the by-product of the manufacture, whilst the liquid ortho compound alone enters the third stage of the process.

It is in this stage that the amido group is introduced into the molecule. This is easily accomplished by either leading a current of dry ammonia gas into the liquid chloride, or by mixing it intimately with dry ammonium carbonate, and heating the mixture. The orthotoluene sulphamide formed is a solid; it is washed with water in order to free it from the ammonium chloride formed in its production, and thus rendered fit to undergo its last transformation into saccharine.

Orthotoluene sulphamide is, as its name implies, still a derivative of toluene. If it be exposed to gentle oxidation, the methyl group which it contains, and which, so far, has remained unchanged, is attacked, and transformed into the carboxyl group. By this transformation the compound ceases to be a derivative of toluene, and becomes a derivative of benzoic acid, viz., sulphamine-benzoic acid, which, however, as has already been explained, being an ortho compound, immediately on being liberated from its salts forms its anhydride saccharine. The practical method of bringing all this about consists in an oxidation with permanganate of potassium. In order to obtain satisfactory results, it is necessary that the liquid be always strictly neutral. Free alkali is liberated, as a rule, in permanganate oxidations. In order to counteract the injurious action of this alkali, a sufficient quantity of sulphuric acid has to be added, along with the permanganate, to insure the strict neutrality of the liquid. Manganic peroxide is formed in the process; but this is separated from the liquid by filtration. The clear, colourless filtrate is a solution of potassic sulphamine benzoate, which, on addition of an acid, immediately deposits saccharine in white crystals.

This process, which has been patented by Dr. Fahlberg and the heirs of Adolph List in Leipsic, has been slightly modified in a subsequent patent. The first stage of the process remains the same; it is followed by the oxidation process, and thus a mixture of the two isomeric sulphobenzoic acids is produced. These are transformed into their chlorides by being treated with chlorine gas in the presence of phosphorus trichloride. Thus the two isomeric sulphobenzoic dichlorides are formed. These are treated with ammonium carbonate. By this treatment the para derivative is transformed into sulphobenzoic diamide, which is quite insoluble in water. The ortho compound, on the other hand, yields ammonium sulphamine benzoate, which is soluble in water, and may thus be separated from the para-diamide. The aqueous solution thus obtained is acidulated, when saccharine settles out in white crystals.

For carrying out these processes the patentees have erected works in Salbke-Westethusen, near Magdeburg. Considerable practical difficulties seem to have been encountered at first in the manufacture, for it is rather less than a year that the works have been able to supply the numerous orders received. It is, therefore, a comparatively short trial to which the new product has been subjected. In conjecturing, as I shall now try to do, the probable use and importance of the new product, I have but few practical results as a basis, and must speak with due reserve. Saccharine has, of course, to be compared with cane sugar. Now, it is quite clear that the complicated process of its manufacture does not allow of its being produced at anything like the cost price of sugar. If, therefore, its sweetening power were only equal to that of

Digitized by Google

sugar, its future would be hopeless. The sweetness of saccharine is, however, quite extraordinary. Of course it is difficult to establish the ratio of sweetness of two substances. It is, however, asserted by competent and impartial judges that saccharine is *two hundred and thirty* times sweeter than the best cane or beetroot sugar. A very small quantity of saccharine will, therefore, go a long way, and may, even at a high price, prove cheaper than sugar. Opinions differ as to the exact "shade," if I may so call it, of the sweetness of saccharine. Some say that its taste is exactly identical with that of the best sugar, others find a marked difference in favour of sugar.

The question is: Have we any reason or inducement to replace sugar by another sweetening agent, and if so, in what cases?

When saccharine was first brought before the public, it was believed by many persons that it would readily supplant sugar in all its uses. At present this opinion is no longer held even by very sanguine judges. To begin with, there is the impossibility of producing sufficient quantities of toluene to provide for the world's want of sugar. Then, saccharine is a mere sweetening agent, whilst sugar is strongly nourishing. Even if we could procure saccharine at the price of sugar (in the ratio of its sweetening power) we would have to eat so much more bread, in order to make up the loss of food by discarding the sugar. Again, although saccharine has on short trials proved quite harmless even in large doses, it is not known what effects it may produce on being taken continually.

There are, however, certain applications in which saccharine does not compete with sugar; and for these it has rapidly gained general favour, and is sure to take and hold a permanent place. One of these applications is based upon the fact that saccharine, with its excessive and overwhelming sweetness, is capable of covering very strong disagreeable tastes. Thus medicines of very unpleasant taste, such as quinine, strychnine, and others, have been made palatable by being combined with saccharine. Saccharine also renders most valuable help in the treatment of certain diseases, in which, like diabetes, a craving for sweet food exists, whilst sugar is prohibited in the patient's diet. In such cases saccharine is a boon and a blessing, for it supplies the necessary sweetness, without participating in the economy of the patient's body. Saccharine is now already very largely used in the treatment of diabetes, and all kinds of preserves, formerly forbidden to the patients on account of the sugar they contain, are now manufactured with the addition of saccharine. Saccharine champagne, saccharine fruit jellies, and coffee and tea sweetened with saccharine, are now common articles of diet with patients suffering from this widespread disease.

Another application has been proposed for saccharine, which, if it be carried out practically, may assume rather large proportions. It has of late been demonstrated that grape sugar may be produced in a practical manner from potato starch in the shape of hard, white, glittering crystals, very much resembling cane sugar. Grape sugar is, however, less sweet than cane sugar, and cannot therefore compete with the latter, although it is quite as nutritious and wholesome. It has therefore been proposed to impregnate pure crystallised grape sugar with such a quantity of saccharine (very little would be sufficient) as to make it exactly as sweet as cane sugar. It would then be able to hold its own against the latter. There is no reason why this suggestion should not be carried out, provided always that saccharine be proved to be harmless, even on prolonged regular use.

Besides its sweetening power, antiseptic properties are also claimed for saccharine. No conclusive experiments seem, however, to have been made as yet in that direction, and it remains for the future to show whether saccharine may justly claim a place in the large array of antiseptic substances for which there seems always to be a want.

Notes.

ELECTRICITY IN THE NAVY.

A REPORT has been prepared by the Engine Room Telegraph Committee, which has been sitting at Portsmouth for the last year, and following out their recommendations the whole of the ships of the "Admiral" class will be fitted with the electric telegraph in addition to the customary mechanical telegraph for communicating between the bridge and the engine room. It is also announced that as the ventilation of the dynamo flats in these ships is so bad that it is nearly impossible for the men to live in them for any length of time, it has been resolved to provide them with peace fittings in the shape of additional dynamos to be placed on the main deck. These will be 100-ampère machines. In time of war the service dynamos, which are below the water line and are protected from shot, will be used for the search lights and glow lamps. Another innovation is to be introduced whereby four projectors will be fixed in each of the Nordenfelt projections at the corners of the superstructure deck, so that in case of an expected torpedo attack the ships will be able to surround themselves with radial beams of light.

BRAZILIAN IMPORT TRADE.

IN reporting on the trade of the province of Saõ Paulo, Brazil, the British Consul at Santos says that in the import trade Great Britain takes the first rank, and may be considered as progressing. Indications exist that the British manufacturer is becoming alive to the necessity of overcoming foreign competition, and that in certain trades, such as glass and earthenware, which were mentioned in the last report from this Consulate as passing into German hands, we are regaining the lost ground to some extent. The Consul, however, points out that much care and attention is required to enable our manufacturers to keep pace with their rivals, as the Germans are constantly improving in design and make, and are always prompt to study the particular requirements of the market.

THE ROYAL AGRICULTURAL SOCIETY.

THE annual report of this Society states that during the past year 393 new members were elected, and that the Society now consists of sixty-six life governors, fifty-six annual governors, 3521 life members, 5225 annual members, and sixteen honorary members. An excellent site for the country meeting of 1889 has been selected in Windsor Great Park, and the Council have every reason to anticipate a satisfactory and successful jubilee meeting. Her Majesty the Queen has consented to accept the position of President of the Society in the coming year. It has been decided by the Council that the country meeting of 1890 shall be held in the district comprising Berkshire, Cornwall, Devonshire, Dorsetshire, Hampshire, Kent, Somersetshire, Surrey, Sussex, and Wiltshire.

LOCOMOTIVES FOR TOWING ON CANALS.

FROM the remarks made by many of the speakers at the recent Conference on Canals at the Society of Arts, it might be supposed that railways and canals are irreconcilable antagonists. Last week, however, an experiment was made on the Shropshire Union Canal at Worleston by officials of the London and North-Western Railway which is suggestive of the lion lying down with the lamb. A set of rails of 18in. gauge was laid down on the canal bank for a distance of about a mile, and a small locomotive from the Crewe railway works was placed on the line. When steam was up two boats were attached by ropes to the locomotive, which drew them along easily at the rate of seven miles an hour. Four boats were then attached, and the same speed was attained. The locomotive worked very smoothly, and the experiment is looked upon as a success.

LARGE SUGAR REFINERY AT PHILADELPHIA.

IN our issue of 27th April our Philadelphia correspondent referred to the new sugar refinery which was to be erected in that city by Mr. C. Spreckles. Some further details are now given by the British Consul at Philadelphia, who states that some of the buildings will be nine storeys high, others eleven storeys: the cost of construction, &c., will be between three and four million dollars, which will include the construction of the buildings and the necessary machinery. The number of men required to keep such an extensive establishment running to its full capacity will be 1500. The consumption of coal will be 250 tons daily, and 15,000,000,000 gallons of water will be required per annum. The raw sugar, beetroot, and cane, to a large extent will be imported by Mr. Spreckles direct from the West Indies and Germany. An ordinary steamer's cargo will be consumed every two days, averaging a daily output of 600 hogsheads. Centrifugal beetroot sugar will be used, about one-third being mixed with two-thirds of cane, and the product will be cube, cut loaf, granulated, and various yellow sugars.

A NEW OIL REGION.

CANADA seems likely to become, at no very distant date, a competitor for a share of the world's petroleum trade. The existence of oil fields in the North-West Territory has long been known, but until recently they were regarded as unimportant. About a year ago Professor Bell discovered that the extent and probable productiveness of the Athabasca River petroleum field had been much under-estimated. He found surface indications of oil over a wide tract of country stretching for about 150 miles along the course of the river, and approaching to within a short distance of the Grand Rapids. He furthermore stated that boring would probably reveal the presence of oil over a very widely extended area. These views have received general corroboration from the newly published report of the Government Committee appointed to examine into the resources of the Great Mackenzie Basin. The report states that "the evidence submitted to the committee points to the existence in the Athabasca and Mackenzie Valleys of the most extensive petroleum field on the American continent, if not in the world." The transport difficulties to be overcome are considerable, but by no means such as to debar the product from European markets.

LIFTS ON CANALS.

IN the course of a paper on canal engineering, read by Mr. L. F. Vernon Harcourt, at the recent Conference on Canals and Inland Navigation, held at the Society of Arts, the author stated that the adoption of hydraulic lifts for connecting two reaches of a canal, where the difference of level is considerable, appears to be growing in favour at the present time. The system is comparatively modern, for though a simple lift, with two counterbalancing troughs, lifted and lowered 8-ton barges a vertical distance of 46ft. on the Grand Western Canal many years ago, it was subsequently abandoned. The first hydraulic lift was erected at Anderton, in 1875, for connecting the River Weaver with the Trent and Mersey Canal. The difference of level is 50½ft.; and the barges are raised or lowered in two wrought iron troughs, 75ft. by 15½ft. with 5ft. depth of water, each resting on a central hydraulic ram, 3ft. in diameter, working in two hydraulic presses underground, which can be connected at pleasure, making the troughs counterbalance one another. One trough accordingly ascends as the other descends, the motion being imparted by removing 6in. of water from the lower trough; and only the final lift of about 4½ft., required when the descending trough reaches the water in the lift pit, has to be effected by hydraulic power. The whole lift is accomplished in 2½ minutes, and one 100-ton barge can be transferred from the river to the canal, and another from the canal to the river, in eight minutes, with an expenditure of only 6in. depth of water over the area of one trough, and the power required for the final short lift. A similar lift, on a somewhat larger scale, has recently been opened at Les Fontinettes, near St. Omer, on the Neufossé Canal, in place of a flight of five locks, which were inadequate for the traffic. The height of lift is 43ft.; and each trough is 132¾ft. by 18⅓ft., containing a depth of 6½ft. of water, and weighing 700 tons, and accommodates barges of 300 tons. On the Canal du Centre, in Belgium, there is a rise of 220ft. in a distance of only five miles, and this is to be surmounted by four hydraulic lifts similar to, but still larger than, the two just described.

EXPLOSIVES.

IN the current number of the "Proceedings of the R.A. Institution," a further instalment is given of Major J. P. Cundill's "Dictionary of Explosives," consisting of Class V., "Gun Cotton and Other Nitro Compounds;" and Class VI., "Picric Powders." The gradual development of the manufacture of gun cotton is traced up to Abel's perfection of the process, and due credit is given to the late Mr. E. O. Brown, of the Royal Arsenal, for the valuable discovery that wet gun cotton can be detonated and its whole power evolved by the use of a dry primer. As the practicability of using gun cotton or some kindred explosive for the bursting charges of shells is at present a matter of Government inquiry, we are not surprised that no opinion is expressed as to the possibility of using any of the various patent powders described. Major Cundill, however, expresses a very decided opinion on so-called "harmless explosives," and referring to the claim of inventors and others that certain explosives give off no noxious fumes, he states that no such explosives exist to his knowledge. If perfect explosion or detonation be achieved, then we have at least a considerable amount of carbonic acid, which is not a harmless gas. In actual work such perfection is, however, exceptional, and we have carbonic oxide and nitrous fumes evolved as well. Men have been killed by poisonous fumes from an explosive which was stated to be absolutely harmless in this way. In the introduction to Class VI. the author says that in 1885 M. Turpin took out an English patent claiming the employment of picric acid, unmixed with any other ingredient, as an explosive agent for military and other purposes. He proposed to compress the acid, to agglomerate and mould it with an aqueous solution of gum arabic, or oils, fats, &c., or to use collodion jelly. When the last named substance is diluted in the proportion of from three to five per cent. in a mixture of alcohol and ether, he states that the blocks of picric acid moulded with it will explode in a closed chamber with a priming of from one to three grammes of fulminate. He also proposed to cast picric acid into projectiles, the cast acid having a density of about 1·6. In shells he dispensed with the use of fulminate, substituting for it a priming charge of violent gunpowder (25 grammes), or a powder composed of chlorate of potash, tar, and charcoal. This invention probably closely resembles melinite, but the exact composition of this explosive is kept secret.

Patent Record.

Compiled from "The Official Journal of the Patent Office," by W. E. Heys, *70, Market-street, Manchester.*

APPLICATIONS FOR PATENTS.

(The names in italics within parentheses are those of Communicators of Inventions.)

ENGINEERING.

5407A. Tarrillion, J. ..... Boats. (This Application having been originally included in No. 5407, dated 11th April, 1888, takes, under Patents Rule 23, that date.)

18th May, 1888.

7366. Sowden, A. ..... Looms.
7370. Oldham, A. ..... Metallic packing for pistons, piston valves, and pump buckets.
7371. Litchfield, L. ..... Drilling machines.
7374. Heaton & Holden ..... Motor engines actuated by anhydrous ammonia.
7377. Wise, W. L. ..... Looms (*Martini & Co.*).
7380. Vering, J. H. ..... Apparatus for driving tunnels in water-bearing soil.
7392. Downing, G. ..... Steam engine lubricators (*Mease*).
7402. Boulton, M. P. W. ..... Steam engines.
7404. Petry & Buch-Muller Repeating breech-loading fire arms.
7409. Durafort & Durafort Manufacture of articles cast in moulds with a covering of a hard metal.

19th May, 1888.

7410. Maxfield, W. B. ..... Taking up apparatus for circular knitting machines (*Heidelmann*).
7419. Stone & Turner ..... Cisterns, tanks, reservoirs, hoppers, drums, and like vessels.
7424. Dronsfield, S. ..... Prevention of snarls and lashed ends in ring spinning and doubling frames.
7430. Wilkinson and Wilkinson ..... Jacquard machines.
7434. Sauvée, A. ..... Quick-firing guns (*Canet*).
7435. Sauvée, A. ..... Ordnance (*Canet*).
7439. Bosshardt, F. ..... Water motors (*Delon*).
7443. Terrers, R. T. ..... Steam engines.
7446. Dombrowski, R. R. von Sporting guns.
7451. Hooker, J. J. ..... Power storing apparatus for stopping and starting tram cars.
7454. Atterton, J. ..... Grinding the blades of lawn mowers and similar machines.
7455. Boult, A. J. ..... Double acting presses (*Roux*).
7459. Wickstead, J. H. ..... Testing machines.
7462. Chambers, J. ..... Tools for expanding and cutting boiler tubes.
7464. Richardson & Greaves Adjusting the covers of carding engines.
7467. Yarrow, A. F. ..... Engines worked by vapour or volatile liquids.
7473. Edwards, G. ..... Interlocking levers for operating railway points and signals.
7474. Jordan & Howard ..... Printing machines.
7477. Blezard, N. ..... Apparatus for causing vessels to travel along waterways.

22nd May, 1888.

7490. Engelson, I. ..... Twist drill grinding machines.
7493. Knowles, J. ..... Machines for printing fabrics.
7495. Gallon & Chapman ... Hydraulic engines for driving capstans.
7496. Allison, H. J. ..... Button hole attachments for sewing machines (*The Harris Button Hole Attachment Co.*).
7499. Ashworth, J. ..... Machinery for stretching and guiding fabrics.
7500. Birley & White ..... Vacuum brakes.
7509. Fletcher, C. W. ..... Weft catching motion for looms.
7513. Liston, J. ..... Machinery for cutting corks.
7514. Calderwood, R. ..... Relieving ropes or chains when subjected to sudden shocks or strains (*Calderwood*).
7518. Groth, L. A. ..... Machines for breaking textile plants (*Céran*).
7521. Wordsworth, C. T. ..... Gas motors.
7526. Payne & Burstow ..... Screw propeller.
7534. Buffington, L. S. ..... Iron buildings.
7539. Schulz, R. ..... Rope winding drums.
7540. Boult, A. J. ..... Freight cars (*Brown*).
7542. Boult, A. J. ..... Carriage trucks (*Youmans*).
7547. Browett & Lindley ... Gas engines.
7550. Brice, T. ..... Apparatus for use as a fire escape and for lowering weights from buildings.
7552. Willcox, B. ..... Machines for sewing straw braid (*The Willcox & Gibbs Sewing Machine Co.*).
7554. Arthur & Garfield ... Steam engines.
7557. Haddan, R. ..... File cutting machines (*Neswadba*).

23rd May, 1888.

7560. Grote, C. F. ..... Music note printing machine.
7565. Munro, A. ..... Type writing machines.
7566. Tennent, J. ..... Supplying feed water.
7567. Ray, R. A. ..... Oscillating fire bars for furnaces.
7575. Barker, W. ..... Carding engines.
7578. Igel, H. ..... Hosiery machines.
7584. Rammoser, A. ..... Washing machine.
7593. Goodbody, W. R. ..... Sewing machines (*Barber*).
7597. Wrigley, J. ..... Forming hot high pressure gaseous material, applicable for producing motive power in engines.
7598. Nordenfelt, T. ..... Machine guns and mountings.
7600. Carroll, C. ..... Apparatus to facilitate locomotion in fluids.
7606. Craven & Sellers ..... Fluid pressure engines.
7610. Armit, R. H. ..... Ordnance.

24th May, 1888.

7614. Krause & Collin ..... Water motors.
7615. Biddiscombe and Hilton ..... Couplings for railway rails.
7620. Tweedale, E. ..... Machine tools for determining the position of the teeth on card flats, and for securing the clothing to the iron flats of carding engines.
7621. Templeman, J. ..... Pressing machines.
7627. McInnes, T. S. ..... Engine indicators.
7629. Barlow & Cree ..... Apparatus for trimming the edges of "hat leathers."
7631. Gruyter, F. A. L. de ... Raising and lowering ships' boats.
7633. Taylor, G. H. ..... Self contained gas fired steam generators.
7639. Pickford, J. ..... Mules and twiners.
7644. Wade & Cherry ..... Rotary engine.
7653. Volker & Nyland ..... Apparatus for insuring the stoppage of locomotives at stations.

ELECTRICITY.

4673A. Justice, P. M. ..... Incandescent electric lamps (*Heisler*). (This Application having been originally included in No. 4673, dated 27th March, 1888, takes, under Patents Rule 23, that date.)

19th May, 1888.

7463. Kotyra, M. ..... Alternating commutator.
7479. Rawson & White ..... Insulation in electrical machinery.
7480. Rawson & White ..... Insulation in electrical wire.

22nd May, 1888.

7487. Binswanger & Coates.. Electric switches.
7522. Houghton, E. J. ..... Dynamo.
7523. Houghton, E. J. ..... Electric lighting.
7530. Chittenden & Vaughton ..... Portable electric safety lamp.
7536. Willcox, B. ..... Galvanic batteries (*Whittier*).
7541. Thompson, W. P. ..... Electric machines (*Spang*).
7548. Dieuleveult, U. ..... Floating telegraphic or telephonic station or apparatus for enabling ships at sea to communicate with one another or with the shore.
7551. Kendall & Cooper ..... Coupling devices for electrical purposes.

23rd May, 1888.

7585. Whalley, A. ..... Telephones.

24th May, 1888.

7619. Weir, G. J. ..... Electric battery.
7636. Appleton, J., & others.. Holders for electric incandescent lamps.

CHEMISTRY.

18th May, 1888.

7398. Avenarius, R. ..... Treatment of tar oils for use as wood-preserving paints or coatings.

22nd May, 1888.

7497. Allison, H. J. ..... Explosive compounds (*Fitch*).
7507. Parnell & Simpson ... Sulphuretted hydrogen.
7511. Dawson & Hirsch ..... Amido-dimethyl aniline chloride.

MISCELLANEOUS.

5008A. Phillips, J. H. ..... Improved vehicle. (This Application having been originally included in No. 5008, dated 4th April, 1888, takes, under Patents Rule 23, that date.)

18th May, 1888.

7361. Lofthouse, R. ..... Ventilating.
7363. Heys, W. E. ..... Selvedge protectors for use in nap raising machines (*Martinot*).
7369. Cordingley and Fletcher ..... Picking sticks for looms.
7376. Hornung, F. ..... Self lighting fuses.
7379. Hamilton, J. C. ..... Retorts for distilling shale.
7383. Cheswright, C. ..... Protecting metallic tubes from external pressure.
7384. Lawson, E., & others ... Ships' berths.
7385. Sauvée, A. ..... Regulating the temperature of places heated by the circulation of water (*Crespin*).
7386. Körber & Steuth ..... Regenerating gas lamps.
7387. Freeman, A. ..... Balancing and regulating cabs.
7388. Pyke, G. W. ..... Rifle and gun target signalling.
7393. Duffy, T. W. ..... Wedge.
7394. Lund, E. ..... Pumps.
7396. Buswell & Buswell ... Tents.
7399. Leigh, H. H. ..... Optical telegraphy (*La Cour*).
7400. Linn, S. H. ..... Process and apparatus for making illuminating and heating gas from water in combination with carbonaceous substances (*Flannery*).
7405. Martin, J. G. ..... Binding bundles of cut crops.

19th May, 1888.

7411. Horn, A. ..... Saccharometers.
7414. Barbour, J. ..... Compressing brass covered rollers for wet spinning frames.
7415. Marsh, E. ..... Glass as a surface for cutting leather.
7417. Burton & Walker ..... Piano keys used in the shedding motion of looms.
7421. Panter, W. ..... Railway carriage doors.
7423. Shaw & Shaw ..... Stop valves.
7425. Ashworth, E. ..... Securing of the clothing to carding engine flats.
7431. McBride, H. ..... Corkscrews.
7432. McKellen, S. D. ..... Photographic cameras.
7433. Wilson & Hull ..... Safety lever for the purpose of moving the bodies of carts and vehicles.
7436. Beevers, J. ..... Cycles.
7437. Johnson, G. ..... Cleaning bottles.
7438. Bosshardt, F. ..... Purifying middlings (*Mistiaen*).
7440. Landless, J. W. ..... Securing the picking strap to the picker in looms.
7441. Bailey, J. ..... Regulating the supply of gas.
7442. Pattison, S. ..... Saddles for velocipedes.
7444. Linley & Biggs ..... Saddles of velocipedes.
7447. Minors, J., & others ... Padlocks.
7448. Onions, W. J. ..... Utilising waste lengths of metal tube.
7449. Wenham, W. P., & others Locks.
7453. Jungbluth, W. ..... Bars for weaving purposes.
7456. Rigby, J. S. ..... Utilisation of the lime mud refuse of sugar for cement.
7469. Spielmann, I. ..... Gas heaters.
7478. Pitt, S. ..... Course and bearing deviation eliminator (*Hart*).
7484. Bland, R. ..... Propelling bicycles and tricycles.

22nd May, 1888.

7505. McRobb, J. ..... Operating the shutters for signalling in mantlets for rifle target practice.
7506. McRobb, J. ..... Operating of targets for rifle practice.
7510. Garrard, C. R. ..... Velocipedes.
7512. Harding, T. W. ..... Machine wool combs.
7524. Kelly, W. P. ..... Lubricant.
7525. Lones, E., & others ..... Coating metal plates with tin.
7528. Williams, E. ..... Sweeping soot from flues.
7531. Hillman, W. ..... Bicycle stands.
7533. Newton, H. E. ..... Purification of water and sewage (*Leeds*).
7538. Boult, A. J. ..... Reflectors for lamps (*Péral*).
7543. Simon, H. ..... Sieving apparatus.
7544. Kendall & Cooper ..... Locking apparatus for railway carriage doors.
7546. Hearington, A. H. ..... Oil lamps.
7549. Slade, C. G. ..... Disappearing targets.
7555. Passburg, E. ..... Vacuum drying apparatus.

23rd May, 1888.

7559. Knoop, A. ..... Receptacles for liquid carbonic acid.
7561. Robbins & Creed ..... Disc tap.
7563. Martin, G. ..... Cycles.
7569. Hastie, W. ..... Copying presses.
7570. Miller, W. ..... Buckets and cans.
7571. Parker, G. W. ..... Street fire alarms.
7573. Letheren, T. W. ..... Preventing water pipes from being frozen.
7576. Shreeve, W. S. ..... High pressure self making joint.
7577. Parker, J. ..... Cycles.
7579. Baker & Le-Masurier Pumping water by means of weights.
7587. Birkovits & Köszegi ... Removing or preventing boiler scale.
7592. Thompson, W. P. ..... Treatment of cotton seed.
7594. Eland, G. H. ..... Seasoning timber.
7595. Gelder, P. van ..... Separating cockle seeds.
7596. Fletcher, J. ..... Protractors.
7604. Bois, W. A. ..... Bolts.
7605. Ketcher, J. L. ..... Springs for carriages.
7607. Kness, V. J. ..... Manufacturing vitrifiable colours.
7608. Orville, G. de. ..... Indicating the presence of noxious gases.

24th May, 1888.

7612. Chambers, G. J. ..... Internally stoppered bottles.
7613. McDonald, J. ..... Self trimming lamp (*Græme*).
7616. Fenby, J. B. ..... Oil burners.
7617. Bardsley, J. ..... Couplings for lead pipes.
7618. Ross, W. ..... Brick.
7624. Cubley & Preston ..... Stopper for bottles.
7630. Douglas & Logan ..... Flanges of copper tubes.
7632. Langlands, A. ..... Velocipedes.
7640. Thompson, W. P. ..... Filtering liquids (*Diebl and Mensik*).
7641. Croker, G. H., & others Cleaning cotton seed.
7646. Heys & Heys ..... Manufacture of plaster or cement.

COMPLETE SPECIFICATIONS ACCEPTED.

Persons interested in opposing the grant of the following patents may give notice of opposition at any time within two months after the dates given.

ENGINEERING.

26th May, 1888.

5591. Edoux, F. L..... Hydraulic lifts.
7335. Snelgrove, W. ..... Weighing machines.
7599. Morris, S..... Slubbing frames.
7739. Brewer, G. ..... Sewing machines (*Jansen*).
7835. Fairfax, J. S. ..... Boilers, flues, and furnaces.
8930. Bellinger, F. C..... Uniting metal plates.
9455. Cook, J. C. ..... Block printing machines for textile fabrics.
9803. Boult, A. J. ..... Button hole attachments for sewing machines (*Blodgett*).
9831. Orr & Brown ..... Fastening sheet metal roofs.
9896. Wadsworth, J. ..... Boilers.
10042. Boult, A. J. ..... Roofs (*La Progresiva Joint Stock Company*).
10047. Perks & Salmon..... Manufacturing hoes, spades, and other tools.
10081. Tatham, R. ..... Ring spinning and doubling machines.
10125. Browne, N. ..... Harvesting machines (*Parkerson*)
10126. Scott, G. A..... Signalling on railways.
10141. Wallace, P..... Spinning, doubling, and roving fibrous substances.
10184. Clarke, W., & others... Steam pumps.
10198. Bull, H. C., & others... Hydraulic engines.
10202. Bull, H. C., & others... Gas motors.
10271. Moffatt, A. C. ..... Hydraulic lifts.
10277. Eadie, P., & others..... Spinning and doubling fibrous materials.
10291. Bennett & Browne ... Manufacture of surgical lint and other fabrics.
10303. Owen, C. G..... Railway and tramway rolling stock.
10340. Baldwin, J. ..... Steam boilers.
10360. Dougill, J. ..... Gas motor engines.
10406. Allison, H. J. ..... Forming metallic ingots in a sectional bar (*Atha & Hinsdale*).
10526. Pass, E. de ..... Paper cutting machines (*Debié*).
12532. Coubrough, H. ..... Bolting machines for flour (*Summerton*).
12687. Nagel, A. C., & others.. Presses with reciprocating pistons.
12810. Carter, J. ..... War ship.
13820. Arundel, H. B..... Machines for doubling and twisting fibrous materials.
16801. Boult, A. J..... Mowing machines (*Mowat*).
17193. Pursall & Lister ..... Fuel economising apparatus for furnaces.
7. Hanson, J..... Chairs for railway rails.
3059. Koerner, A. C..... Breech mechanism of rapid-firing guns.
3248. Jones, C. W..... Spinning and doubling machinery.
3508. Thompson, W. P..... Cable coasters, carriers, and rope way bridges (*Van Zandt*).
4296. Evenstad & Senstad... Machines for making wood wool.
4297. Pistoja, A. G. von B. di Torpedoes.
4432. Cito & Funck ..... Lifting jacks.
4850. Jucker, J..... Looms.
4902. Lake, H. H. ..... Railway ties (*Sea*).
4981. Jarvis, S. E..... Steam engines.
5339. Bradbury, C. ..... Apparatus for lifting doors (*Messrs. Grimme Natalis & Co.*)
5566. Russell & Cooper..... Anchors.
5739. Gould, C. E..... Manufacture of rolled metal articles.
5890. Hawkins, F. P..... Steam engines.
5915. Pitt, W. A. ..... Steam engines.
5980. Gibbs, W. A..... Furnaces.
5989. Buxton, J. H., & others. Newspaper printing machinery.
5997. Turner, C..... Loose reed looms.
6032. Hallatt, B. ..... Twist lace machines.
6097. Lake, H. H. ..... Repair of ships' propellers under water (*Kirkham*).
6159. Vismes, Count A. V. de Drilling holes in metal and stone.
6951. Bookwalter, J. W..... Converting crude iron into malleable iron or steel.

ELECTRICITY.

26th May, 1888.

5648. Holmes, J. H. ..... Making and breaking electric circuits.
9017. Cross, W. ..... Electric furnaces.
10240. Hanson, L..... Field magnets.
10454. Gent & Ellery ..... Electrical signalling apparatus.
5362. Holmes, J. H. ..... Arc lamps.
5713. Hallock & Blickensderfer ..... Electric elevators.
5913. Heaviside, A. W..... Electric insulators.

CHEMISTRY.

26th May, 1888.

5896. Kern, A. ..... Sulpho nitrosulpho, nitrosulpho, and amidosulpho acids.
8929. Güttler, H..... Manufacture of charcoal for explosives.
10153. Fleming, J. ..... Calcining of sulphurous ores.
10168. Knowles, W. H. ..... Generating carbonic acid gas (*Pohl*).
10554. Walton, J. A. ..... A liquid blue.
5949. Kuhnt & Deissler..... Explosive compounds.
5971. Haddan, H. J. ..... Percolators for the extraction of oil by the naphtha process (*Evans*).
6102. Jensen, P..... Extracting metals from ores (*Russell*).

MISCELLANEOUS.

26th May, 1888.

7502. Boyce, G. R..... Combination locks.
7727. Dyer, J. W. ..... Cartridges for signalling.
8194. Baillard, C. L. ..... Preparation of mineral oils.
8398. Edwards, G. ..... Expanding apparatus useful for fire escapes, scaffolding, ladders, observatories, piers, pontoon and other bridges.
8442. Young, W. ..... Valves.
8498. Adamson & Hall ..... Miners' safety lamps.
9063. Nockold, F. ..... Cutting diamonds.
9571. Redfearn, J. A. ..... Miners' picks.
9694. Stokes, F. W. S. ..... Cement.
10085. Toft, C..... Decorating of pottery.
10132. Doulton & Marshall. Manufacture of spiral tubes, rods, and pedestals of terra cotta.
10207. Brooke & Brooke..... Stoppering bottles.
10221. Walker, W..... Ventilating buildings.
10268. Payne & Davison ..... Gas kiln for burning pottery.
10311. Haines, E. ..... Cocks and spreader appliances.
10331. Cooper, J. ..... Shuttles for weaving.
10345. Townsend, G. ..... Velocipedes.
10350. Gehre, M. ..... Superheating of steam.
10361. Phillips, J. ..... Ventilation of sewers.
10385. Larsen, E ..... Slag cement.
10420. Green, W. ..... Treating waterpoof fabrics.
10443. Tabary, C. P. ..... Metallic cement.
10558. Guibout, O. E..... Lighting and heating by means of gas.
10693. Hillman, W. ..... Ball bearings for velocipedes.
10829. Clay, J..... Saddles of velocipedes.
11406. Rae, R. J. ..... Capstans.
12038. Doran, J. S. ..... Heating apparatus (*Reilly*).
13248. Barlow, E. G. B..... Apparatus for inhaling nitrous oxide gas.
13474. Heath, A..... Ornamentation of metallic mounts.
13528. Thrush, J. M. ..... Traps for drains.
14296. King, F. J. ..... Manufacture of metal chests.
14714. Wescott, J. ..... Stop valves.
14798. Johns & Johns ..... Stoppers for bottles.
16355. Johnson, J. Y...:..... Decorating glass (*Aubriot*).
1851. Johnson, J. Y..... Graphophones (*The Volta Graphophone Co.*).
2177. Sickels, F..... Locks.
2744. Smith, D. ..... Indicators for railway carriages.
2870. Tuthill, E. ..... Preparation of an oil or tar from birch tree bark.
3671. Halstead, C. ..... Covering for rollers or pulleys.
4686. Bulpitt, W. H..... Lamps.
4866. Sanders, A. ..... Lamp fittings.
4971. Kertsch, C..... Preventing waste of water in pipes.
5180. Walker, A. H..... Sea oiling projectile.
5327. Peters, G. M. ..... Cartridges.
5331. Haddan, H. J. ..... Gas burners (*Jackson*).
5350. Godfrey & Meeker ... Fire extinguishing apparatus.
5384. Birchall, C. F. B., & ors. Reproduction of designs upon glass.
5698. Fontenilles, J. M. E... Air pumps.
5859. Gutensohn, A..... Coating iron plates with tin.
5860. Skarek, J..... Keyless watches.
5950. Rawlings & Rawlings. Blow pipe apparatus.
5970. Burrow, W. B., & ors... Apparatus for bottling liquids.
5976. Utter, H..... Barbed fencing.
6126. Kilner, T..... Tools for forming glass bottle necks.
6150. Heenan, R. H..... Apparatus for mixing substances.

PATENTS VOID THROUGH NON-PAYMENT OF RENEWAL FEES.

(*To the 19th February, 1888, inclusive*).

Year 1884.

ABSTRACTS OF BRITISH PATENT SPECIFICATIONS.

Compiled from the Published Specifications by W. E. Heys, 70, *Market-street, Manchester.*

ENGINEERING.

Converters.—*W. P. Thompson, Liverpool.* (*G. L. Robert, Stenay, France.*)—The construction of converters according to the present invention will be understood by reference to the accompanying figures, which represent a vertical and horizontal section respectively of one form described in the specification. The cross section is made rectangular with rounded corners. The tuyeres D are arranged in a straight line on one side only

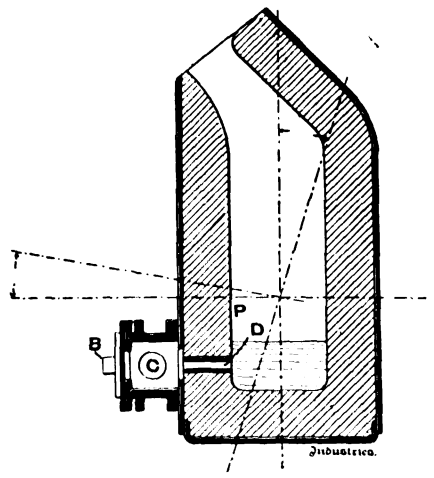

Fig. 1.

of the converter, and they open into a box C into which the blast enters from the supply pipe G. This box is provided with sliding glazed sight holes B, which are carried by a removable back plate. The plane in which the tuyeres are formed is parallel to the axis of rotation A A¹ of the converter, so that whatever the inclination of the latter and the height of the fused metal may be, the head of pressure on the orifices of each of the tuyeres is always the same. The cross section of the tuyere orifices is a rectangle having its corners rounded off so that the blast is injected in rectangular currents. This form of air current is found to give a greater force of penetration than that with the circular section, and it also gives a greater surface of contact between the air and the metal for the

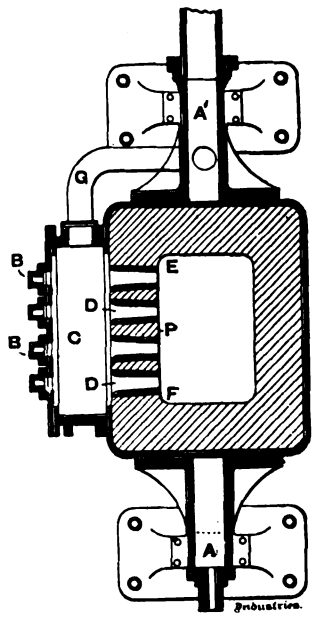

Fig. 2.

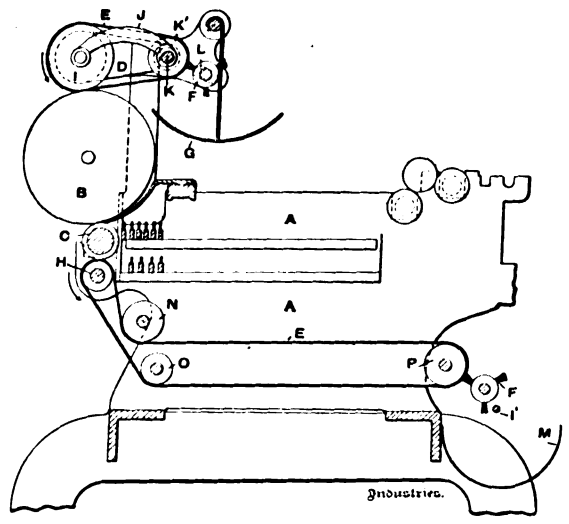
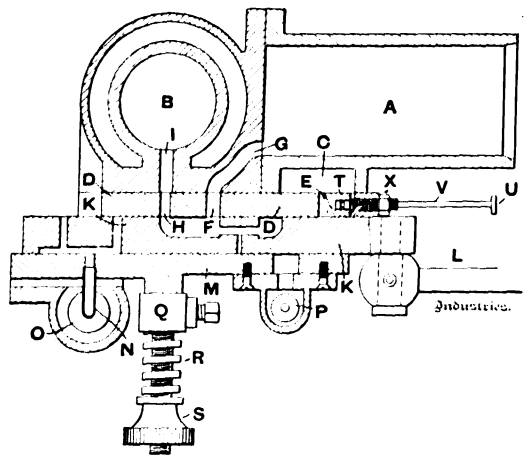


same sectional area. In another arrangement of the converter the cross section is elliptical, but with a straight face parallel to the axis of rotation, on which the tuyeres are disposed in the same way as before. The tuyeres placed thus horizontally form different angles with the straight face; the object of this arrangement is to facilitate the imparting of a gyratory motion to the fused metal. Six claims are made for the single row of tuyeres arranged in a plane parallel to the swinging axis, and for the combination of the sight holes, and for the common air chamber C.—No. 10659. August 2nd, 1887. 8*d*.

Disintegrators.—*J. A. Yeadon & R. Middleton, Leeds.*—The type of disintegrator in which two revolving cages are mounted on a fixed horizontal shaft, has the disadvantage that its bearings cannot be properly oiled. This invention is intended to remedy this defect by affording an improved means of oiling the machine. A central chamber for holding the oil is made as usual by arranging recesses in the boss of each cage; a hole is also formed through the axis of the fixed shaft, and transverse holes are arranged in a line through the boss on one side so as to tap the oil in the recessed space through the fixed shaft in

Digitized by Google

order to tap the central oil hole, and also through the other side of the boss. By this means any clogged oil may be easily dislodged by thrusting a rod through the hole in the central shaft and through the three holes when they are in line. The two holes in the boss are fitted with caps. An oil cistern is placed in an elevated position above the shaft so that the feed shall be under a small pressure. The arrangement of this invention allows the fixed shaft to be moved round into different positions in order to make up for wear and tear. The fixed shaft is firmly held on one base plate, which is cast solid with the vertical standards, and in the standards are formed oil pockets into which the waste oil can be run. Two claims are made, for the manner of lubricating, and for mounting the shaft on two standards cast in a solid piece with the base plate with pockets as described.—No. 8671. June 16th, 1887. 8*d*.



Spinning Machinery.—*J. Wallace, Belfast.*—This invention introduces an improvement in the rubbers or cleaners used for keeping the rollers in a clean condition, and for preventing the adherence of fibres to them. The ordinary rubbers hitherto in use are made of flannel, fastened to revolving bosses which press against the rollers; this arrangement is liable to allow some of the dirt to pass from them to the material which is being operated on. The present inventor employs cleaners which are made of travelling bands of flannel or other material, and means are also provided for automatically cleaning these rubbers. The accompanying figure illustrates the application of this method. A is part of the frame of the machine, B is one of the pressing rollers, and C one of the boss rollers. A roller I of metal is carried by the arms J pivoted upon a driving shaft K, so that

the rubber roller I will rest upon the pressing roller B with a freedom of movement towards and away from its axis. A boss K¹ is fixed on the driving shaft K, and round the roller I and the boss K¹ is passed a leather driving belt D and a band of flannel E. Near to the driving shaft K is placed a brush F, which cleans the belt E, and keeps it rough, and the axle of the brush is mounted in slots L; the trough G catches the droppings from the brush. In applying this method of cleaning to the boss roller C, the inventor passes another belt of flannel E round a revolving roller H, under the guide pulleys N O, and round a roller P; and a similar brush F and trough M are employed. This belt also carries the droppings from the fallers, and delivers them into the same receptacle. A rod may be fixed in close proximity with the revolving brush F, in order to free it from any dust which becomes attached to it. Four claims are made for this rubber, which consists of a travelling belt of flannel arranged as described.—No. 5985. April 25th, 1887. 8*d*.

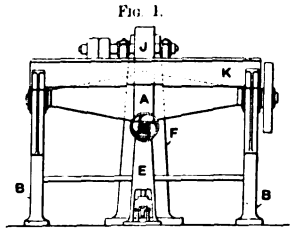
Gas Engines.—*H. T. Dawson, Salcombe, Devonshire.*—Besides varying the quantity of gas admitted to the cylinder, the inventor causes the governor to regulate the degree in which the gas and air are intermixed, so that as the speed of the engine diminishes a less intimate mixture is obtained, and *vice versâ*. For this purpose a cylindrical mixing chamber is employed, whose length may be varied by the governor, or baffle plates are arranged in the mixing chamber, which are turned by the governor in order to lengthen or shorten the distance traversed by the gas and air. A certain minimum amount of mixture is partly secured by fixing interference rings, and partly by a gauze at the entrance to the cylinder. The motor cylinders are kept at an approximately constant temperature by water spaces in the sides and covers of the cylinder, and these spaces communicate with cisterns, so that the surplus heat is dispersed by radiation and evaporation. An interrupted jacket of different proportions, according to circumstances, is also employed, with the object of sustaining a higher temperature than usual in the cylinders, and the water in the jackets may be allowed to boil by throttling the inflow circulating pipe by a valve. The ignition apparatus is modified by a jet of air which plays between the flat flame and the ignition port; at the other side of the flame a platinum coil is arranged for the purpose of lighting. An automatic gas cut-off valve consists of a ball valve on a seat in a chamber in the gas supply passage. The valve normally keeps the passage closed; but a striking pin, which is actuated by a lever engaging with a pin on the crank shaft, raises the ball at each revolution. The pistons and cylinders are lubricated with black lead or other dry lubricant formed into pellets, which are contained in short tubes in the cylinder or piston, and which are pressed against the surfaces by springs. A compound movement of translation and rotation of the pistons spreads the lubricant over the surfaces, and depressions may be made in the surfaces in order to assist in spreading the lubricant. In some cases the lubrication is effected by a powder, which is injected automatically into the cylinder at each explosion of the charge. Baffles are placed in the cylinder in order to control the disposition of the combustible and non-combustible elements of the charge. In particular, a baffle is arranged opposite the ignition port inside the cylinder, in order to cause a slight delay in the ignition; and a deflector is placed in the air aperture in the cylinder, to soften the ignition. The head of the piston is covered with asbestos. For rotating the piston, a bracket is fixed to the piston at some distance from its centre, and the end of the bracket remote from the piston is connected by a universal joint to a bent arm fixed to the connecting rod. As the connecting rod swings to and fro, it carries with it the end of the bracket, and thereby turns the piston. Seventeen claims are made for these various arrangements.—No. 6501. May 3rd, 1887. 11*d*.

Gas Engines.—*R. Wallwork, Manchester, and T. Sturgeon, Ilkley, Yorkshire.*—In most gas engines the air is drawn through a port, and in its course towards the cylinder it travels past a number of holes, through which the gas flows in. The present invention consists in making the port through which the air is admitted adjustable, so that the amount of air can be controlled to suit the quality of the gas. The accompanying figure shows the application of this principle to the gas described in the specification of Patent No. 4923 of 1887 granted to T. Sturgeon. A is

the charging cylinder, B the working cylinder, and C is part of the air passage. D is a loose plate, in which are formed the air port E, the mixture port F, and the firing port H; the port F communicates with the charging cylinder by the passage G, and the port F with the working cylinder by the passage I. The slide valve K is shown in the position it assumes when the charge is being driven from the charging cylinder to the working cylinder. The cover M carries the igniting tube N, the chimney O, and the gas valve P, and is kept up in its place against the valve by the usual clamps Q, springs R, and nuts S. An adjustable slide in the air port in the loose plate is shown at T, and can be moved in and out by turning the milled head U on the long spindle V. By screwing up this rod the size of the air port can be varied to suit the requirements of the case. One claim is made for making the port through which the air is admitted adjustable.—No. 7925. June 1st, 1887. 8*d*.

Machine for Dressing Hides.—*M. Martin & V. Martin, Paris, and E. Schloesser, W. Schloesser, & F. Schloesser, London.*—This machine is intended for scraping and smoothing hides and skins, and for other operations necessary in their preparation for tanning. In the accompanying figures are shown a front and side view of one form of the machine. J and A are revolving cylinders, the lower one of which can be raised or lowered by means of the pedal C and lever D to bring it more or less near the cylinder J, according to the thickness of the skins under operation. The pressure regulator F fixes it in position when adjusted. This regulator comprises two bevel wheels G H, a fly wheel I, and a screw working up and down in the centre of the

Fig. 1.



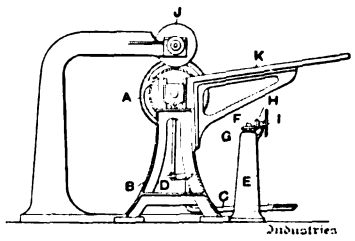


Fig. 2.

wheel G; on turning the fly wheel, this screw rises or descends, and its lower end presses on the pedal C and keeps it in position. The cylinder J may be furnished either with sharp spiral blades running from right to left, or with helical blades on one side only; the same effect may also be produced by a coating of emery cloth. The skin is placed on the table K so that the operator can feed it by hand. When used for smoothing the skins, the cylinders are plain and are heated internally by gas or steam. Another form of apparatus is also described in the specification. The supports B are removed together with the cylinder A, and instead a sliding table is substituted which is worked by hand. Two other rolling tables are mounted on this one, and the skins are placed upon the uppermost of them. In both forms of apparatus there are blades of india-rubber fixed upon the cylinders in front of the cutting blades, their purpose being to spread the skins out before the shaving takes place. Six claims are made.—No. 2154. February 13th, 1888. 8*d*.

ELECTRICITY.

Electrical Transformers.—*W. J. Muller, London.*—In the induction coils as at present manufactured the outer layers of the wire of the secondary coil are less influenced by the electromagnet than the inner layers. The improvement introduced by the present inventor consists in winding another primary coil outside the usual secondary wire, in order to make the induced current more uniform. Outside this second primary wire is laid a series of iron wires forming a second core. Two primary coils are thus obtained, and two iron cores influencing the secondary coil. The primary coils may consist of two or more layers, the outside wire being preferably stouter than the inner one. When large quantities of wire are to be induced, the wire of the secondary coil is wound by the disc method; and sometimes another layer of wires may be wound round the outside core in order to intensify its magnetisation. The two primary coils are wound and connected together in such a manner that when a current is passed through them a uniform magnetic field is produced. Two claims are made for the induction coil in which second primary coils and cores are employed as described.—No. 6204. April 28th, 1887. 8*d*.

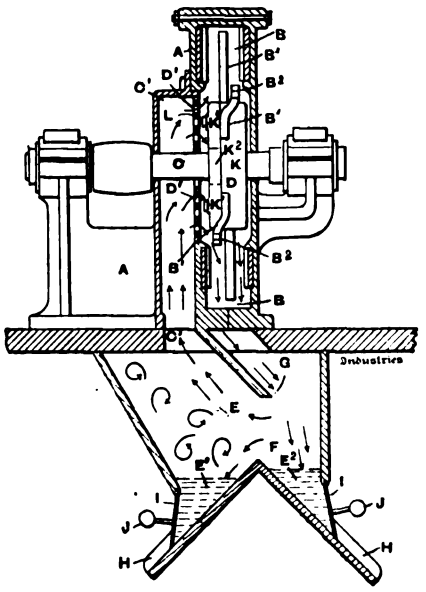
Regulating Dynamos.—*J. Feaveryear, London.*—The magnetic field of a continuous current dynamo is here arranged in such a way as to allow of a constant e.m.f. being maintained at its terminals; the generator may also have its field magnets arranged in series with the external circuit, in which case any variation of the external resistance would cause a corresponding variation of the e.m.f. at the terminals. Several methods are described for carrying out this invention; in one example, a pair of vertical field magnet coils are mounted upon a swivel stage. Two pole pieces are rigidly fixed with respect to the bore of the field surface by means of two connecting pieces of brass. An extension on each pole piece is arranged to carry two vertical field magnets of the bobbin type, which are mounted on a transverse yoke pivoted to the extension of the lower pole piece. The bolt which passes through the bobbin nearest to the field surface fastening it to the pole pieces, acts as its magnetic core. This bobbin is wound with thin wire, while the other is wound with thick wire, so that the latter may be included in the external circuit when in action. The fine wire is preferably of three hundred times greater resistance than that of the external circuit. The generator can be readily converted into a shunt or series machine, according to the work requiring to be done, by simply unscrewing and removing the bolt which passes through the bobbin wound with fine wire. Six claims are made for the various ways of converting the machine into a series or shunt machine, for the purpose described.—No. 2515. February 20th, 1888. 8*d*.

CHEMISTRY.

Mordants.—*W. Crowther & J. Crowther, Dewsbury.*—The mordants employed by the inventors are the acetates of alumina, copper, iron, and chromium. A cold or tepid solution of these metallic acetates, either separately or conjointly, is used as a bath; and after the wool, yarn, or cloth has remained therein for three-quarters of an hour it is wrung out and suspended in a wet state for some hours. The fibres are then dried and heated in order to remove the acetic acid, thus leaving the insoluble oxides firmly fixed upon the goods. It is claimed for the use of these acetates that blacks and blues do not turn green on exposure to light, and that the goods are not impoverished so much by the subsequent dyeing process. Three claims are made.—No. 9027. June 25th, 1887. 6*d*.

Sulphate of Cobalt.—*W. N. Hartley, Dublin, and W. E. B. Blenkinsop, London.*—This invention relates to improvements in the manufacture of sulphate of cobalt and its separation from other metallic sulphates. For every ten parts of the metallic oxide in the cobalt ore five and a half of sulphur is taken, or twenty-eight parts of pyrites containing 45 per cent. of sulphur. This mixture is placed in a covered crucible or upon the hearth of a reverberatory furnace, and heated with as little access of air as possible to a temperature near that of melting zinc. Air is admitted freely when a barely perceptible red heat has been reached, and the mass is caused to burn. When the combustion becomes so slack that the mass no longer burns when stirred, the temperature of the furnace is raised and maintained as long as it is possible that the materials will absorb oxygen. On treating the mass with water, after it has been removed from the furnace, the cobalt sulphate gradually dissolves. Special methods are also described for separating the sulphates of other metals present in the ores. Two claims are made.—No. 8922. June 22nd, 1887. 6*d*.

Obtaining Sulphur from Sulphides.—*C. F. Claus, London.*—The ores containing sulphur, more particularly pyrites and blende, are broken up into suitable pieces, and charged into a deep kiln, which is built of brick and covered with an iron plate. Highly superheated steam, either alone or mixed with hot air, is passed through this deep layer of sulphides from the top downwards. The effect of the steam is to expel part of the sulphur, and to reduce the sulphides to monosulphides, or to reduce the monosulphides to oxides, at the same time giving off sulphuretted hydrogen. Apertures are made at various heights in the kiln, through which regulated quantities of air are admitted to burn with the hydrogen of the sulphuretted hydrogen. The fresh ores are fed in at the top of the kiln through a charging door, or by means of a bell cover, such as is used in a blast furnace; and there is also a door at the bottom of the kiln to allow of the discharge of the residual oxides. An aperture is provided near the bottom of the kiln for the escape of the volatile products given off. In smelting works, where there is an abundance of waste heat, the heating of the steam



Digitized by Google

or air may be effected at a very small extra cost. The kiln may be either vertical or horizontal: in the latter case it is subdivided into compartments similar in principle to annular brick kilns. Each compartment is connected to the adjoining one by means of flues, which can be closed by dampers, and may also be separated from the others for charging. An opening in each compartment communicates with the sulphur chamber. The heated air and superheated steam enters the last one charged with fresh ore, and passes on from one chamber to another until it arrives at the last. Three claims are made for obtaining free sulphur from the sulphuretted hydrogen by passing superheated steam and air through metallic sulphides, and by admitting free air to burn the hydrogen of the sulphuretted hydrogen, and for the two methods of carrying out the process.—No. 6909. May 11th, 1887. 6*d*.

Permanganate of Soda.—*G. H. Bolton, J. R. Wylde, & H. Auer, Widnes.*—The alkaline manganate obtained by igniting a mixture of oxide of manganese and caustic alkali always contains a quantity of these ingredients still uncombined. The inventors therefore treat the aqueous solution of the ignited mass with chlorine; by this means the alkaline manganate is converted into permanganate, and the caustic alkali into the corresponding hypochlorite, chlorate, or chloride. The insoluble oxide of manganese left after lixiviation, if sufficiently pure, may be furnaced with a fresh charge of caustic alkali. The mixed solution of alkaline permanganate and hypochlorite possesses strong bleaching and deodorising properties. If the material is required in a solid state, the water is driven off by heat, and during the evaporation the hypochlorite is converted into chlorate and chloride; and the latter, when soda is the alkali employed, is fished out from time to time. Almost pure permanganate and chlorate of soda is thus obtained. Four claims are made.—No. 8217. June 8th, 1887. 6*d*.

MISCELLANEOUS.

Pulverisers.—*G. Little, London.*—The main object of this invention is to diminish the back draught which is caused by the revolving beaters, by combining with the disintegrating chamber a return air chamber, through which the air shall pass in a continuously circulating current. In some cases the current of air is utilised for the purpose of sorting and separating the pulverised material. The accompanying figure shows a vertical central section, with a separating chamber attached. B is the disintegrating chamber, and C is the spindle on which the beaters are attached; a perforated screen is fixed round the cylindrical part of the chamber, and is fastened to the two end pieces. The

pulverised material passes through these perforations into the chamber E, together with the current of air; the air returns by the passage C¹, through the holes D¹, and into the chamber B. The separating chamber has an inverted V shaped bottom, and is provided with deflecting plates G. The two compartments E¹ E² are provided with doors I I¹ which open when a sufficient weight of material has accumulated. The beater arms B¹ are secured to the hub in such a way that only a small number of bolts are required; the hub is made in two parts, and a number of dovetail slots are formed in them to receive the beaters, which are secured in their places by bolts passing through the two parts of the hub. Six claims are made, for the continuous circulation of the air, for the separator, and for the improved construction and arrangement of the beaters.—No. 8054. June 3rd, 1887. 8*d*.

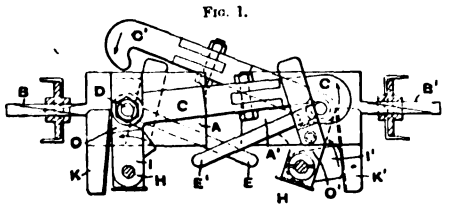
Purifying Petroleum.—*W. H. Pitt & G. H. Van Vleck, Buffalo, New York.*—The object of this invention is to distil petroleum, in order to remove the disagreeable odour which is detrimental to the sale of such oil. The hot vapours of the oil are passed through and around a heated metallic substance suitably comminuted, which exercises an affinity for the sulphurous and other objectionable vapours. One claim is made for this process.—No. 3830. March 13th, 1887. 8*d*.

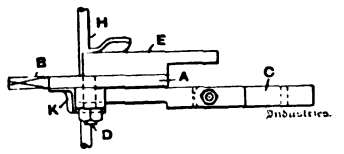
Wood Pulp.—*H. J. Simpson & G. de M. Mackirdy, Liverpool, and A. Taylor, Edinburgh.*—Up to the present time the bark and wood of the Californian redwood tree has been practically useless in commerce. The bark consists of three parts—a rough outer bark, a fine bast fibre immediately below the outer bark, and the remaining main bark. Of these the inventors have found that the outer bark is applicable for making a coarse pulp suitable for conversion into coarse and brown paper and felting; that the bast fibre may be used as a textile material; and that the main bark and the wood is particularly adapted for making cellulose. The bark or wood is cut up into blocks of a size which will preserve the continuity of the vegetable fibre. The rough outer bark and the bast fibre may be removed by mechanical or chemical means, and the remaining portions are then steeped in heated vats containing a solution of caustic alkali. The liquor resulting from this treatment is removed after four hours, and the partially pulped material is subjected to the action of dilute sulphuric or hydrochloric acid in hot water. The gallates and kinos will now be deposited, and may be removed. When the pulp is to be used for felting, the last process may be dispensed with, and the material treated instead with alkali with the addition of sulphate of alumina or copper. Three claims are made.—No. 8817. June 18th, 1887. 6*d*.

GERMAN PATENT ABSTRACTS.

Railway Coupling.—*A. Bolzano, Augsburg.*—This invention shows a new form of automatic coupling for railway carriages. The draw bar B carries at its end a plate A, to which a hook C is connected, pivoting round the horizontal pin D. The other side of A is provided with an inclined plane E. In shunting the

Fig. 1.





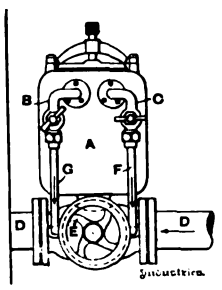


Fig. 2.

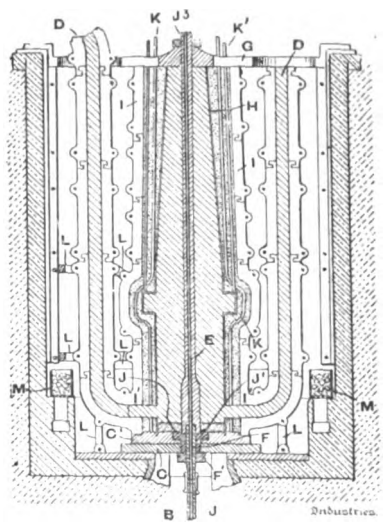
carriages together, the hooks slide along the inclined planes, and engage with the upper ends of the latter. The hooks C are provided with projections O to which the shafts H are connected. These shafts are fitted with cams I. In order to disengage the hooks, or to prevent their engaging, the cams I are put into the position shown on the right hand side of Fig. 1, when they engage with projections K, and lift or keep the hook in the position indicated.—No. 42978. August 27th, 1887.

Feed Water Purifier.—*E. Mertz, Basle.*—This apparatus is intended for introducing chemicals for purifying purposes into the feed water of boilers. A vessel A, supported on the valve E, is charged with the chemicals in use for purifying the feed water.

E is introduced into the feed water pipe D, and connected with A by means of the tubes F and G, which are provided with the valves B and C. Part of the feed water ascends through F into A, is saturated with the chemicals contained in A, and descends through G, when it is mixed with the rest of the feed water.—No. 42697. September 20th, 1887.

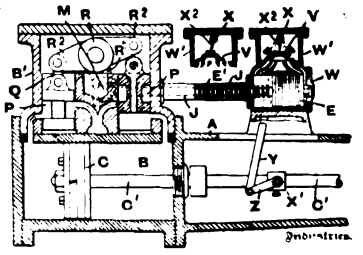


UNITED STATES PATENT ABSTRACTS.

Carding Engines.—*A. Falls, Lowell, Massachusetts.*—In order that the stripping mechanism may have a quicker motion while stripping the top flats than while passing from one flat to the next, a portion of the periphery of the stripping cam gear is provided with double teeth; the actuating pinion has a member provided with a single tooth, which, at the proper time, engages the double teeth, and imparts a slower motion to the cam gear. One claim is made.—No. 382598, dated 8th May, 1888.

Fertiliser.—*S. L. Goodale, Saco, Minnesota.*—The present invention relates to a new process for utilising hydrated aluminium and iron phosphate as a plant fertiliser. The crude mineral which contains the phosphate is first pulverised, and is afterwards heated with carbonaceous matter and sulphuric acid. The resulting product is then suitable for use as a manure. One claim is made.—No. 382604, dated 8th May, 1888.

Looms.—*W. Driver, Mannville, Rhode Island.*—This invention introduces a new arrangement for checking the picking mechanism of looms. The check rod is supported in hangers on the shuttle box; a spring rests against one of the hangers and encircles the rod, and also bears against an adjustable stop on the rod, thereby permitting the regulation of the tension of the spring. The stop on the rod is made of various interchangeable forms, in order to adapt it to the different species of picking mechanism. Three claims are made.—No. 382640, dated 8th May, 1888.



Casting Ordnance.—*R. J. Gatling, Hartford, Connecticut.*—The accompanying figure represents a vertical section of an improved pit and flask for casting large guns. The pit is built of brick work, and is lined with a metallic lining, and an annular fire box M surrounds the lower end of the flask and run ways. The metallic flask I is made in sectional parts, which are provided with annular grooves and projections for interlocking

with one another. The run ways D are built in the same way A thin metallic shell H forms the outline of the mould, and between H and I is placed a packing. The central tube E, forming the bore of the gun, is supported by the brace J³ and by the lock nut J. The base pieces C C¹ are fitted with central openings to receive a hollow uniting bolt, which is also internally threaded, to receive the lower end of the tube E. The lateral brace pieces L are formed with a bend, so as to provide for the expansion of the flask. Seven claims are made.—No. 380756, dated 10th April, 1888.

Whip Roll for Looms.—*D. Durkin, Northbridge, Massachusetts.*—This improvement comprises a yielding whip roll, which is designed to obviate accidents when the shuttle is caught in the shed, and to prevent the occurrence of thin and thick places in the fibre after the stoppage and re-starting of the loom. Springs co-operate with the journal boxes, in order to permit the bearing roll to be moved bodily in an approximately horizontal plane towards and from the breast beam and the fell of the cloth, and an arm and rod are provided for vibrating the bearing rail. Two claims are made for this whip roll.—No. 381617, dated 24th April, 1888.

Slide Valve.—*J. H. Fogarty, New York, and F. M. Wheeler, Montclair, New Jersey.*—This slide valve is actuated by steam and not simply by a mechanical connection with the moving parts of the engine. The two valves P are connected by means of the links Q with the double lever R² which oscillates on the pivot R³. The reciprocating movements of the valves P are imparted to them through the lever R² by the arm R¹ and rod J. The rod J receives its motion from the auxiliary cylinder W, in which the piston E is made to work by means of an ordinary slide valve V. The rod X has a tongue X², which shifts the slide valve V, and is attached to the rod Y, which transmits motion from the main piston rod C¹. The valves P are balanced by the steam pressure on both sides. The exhaust steam passes between the two cylindrical bosses of the valve; in the figure the piston is travelling to the left, and the steam

is leaving the space at the left hand side of the piston and is passing to exhaust; the steam is entering on the right hand side. Three claims are made for this steam actuated slide valve.—No. 380882, dated 10th April, 1888.

The full specifications of the British and United States patents, and the Official Journals of the German Patent Office, from which the above abstracts have been compiled, and the Official Journal of the United States Patent Office, may be seen by subscribers and clients at the Reading Room, Manchester Office of Industries, *where also Patent Indexes from* A.D. 1617 *may be consulted. Copies of the British specifications may be obtained on application to* H. Reader Lack, Esq., *Comptroller-General, Patent Office, Southampton Buildings, London, W.C. The published price must be remitted, together with a sum sufficient to cover postage, which may be reckoned at ½d. for every 10d. or fraction of 10d. Remittances exceeding one shilling must be made by Post Office Order.*

TURNER'S IMPROVED STEAM ENGINE AND BOILER.

(For description see next page.)

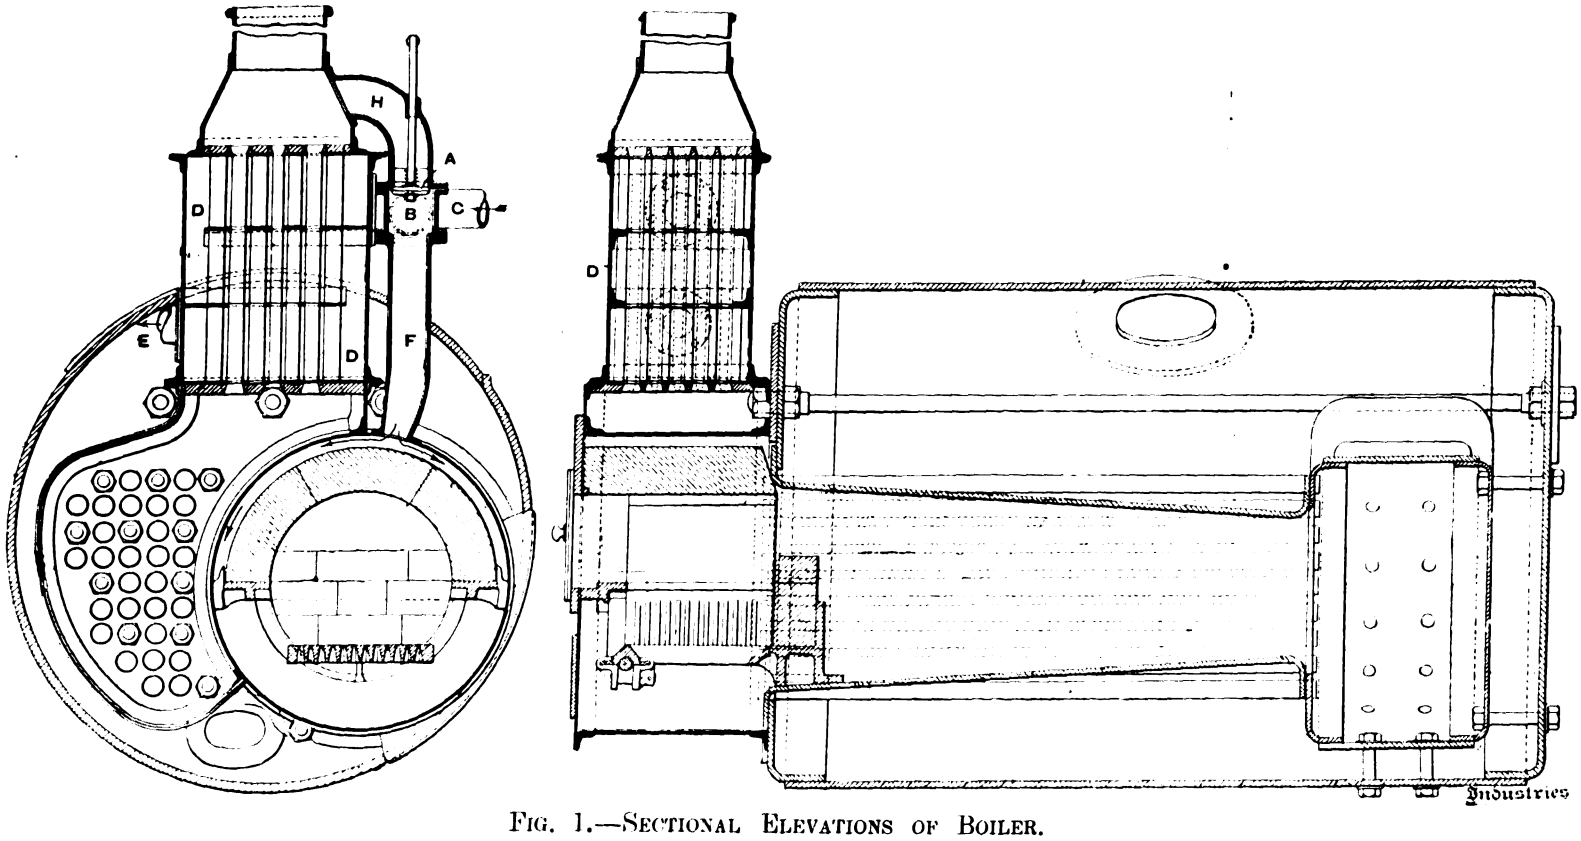

FIG. 1.—SECTIONAL ELEVATIONS OF BOILER.

NOTES ON SCREWING APPLIANCES.

IV.

(Concluded from page 235.)

CHASERS.—These tools are used for cutting threads by means of a lathe. There are two kinds of chasers, viz., those clamped to the slide rest, which is moved along by the "guide screw" at a rate corresponding to the number of threads per inch cut by the chaser; and those which are fitted into a wooden handle and are used by hand. Both classes of these tools are subject to slight modifications in form, for cutting internal and external threads. Figs. 1 and 2 show chasers for use in a lathe. Those for hand use are lighter, and tapered at the back end for fixing them into the handle.

In small engineering works which make their own chasers, and also in some works where the manufacture of screwing tackle is a specialty, a piece of steel is clamped to the slide rest, and a plug-sized master tap revolved between the centres of a screw cutting lathe, the guide screw being geared in the same manner as if a screw of the same pitch as the thread of the tap, which is called

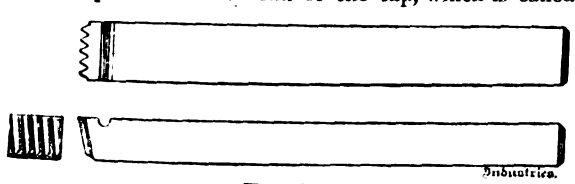

FIG. 1.

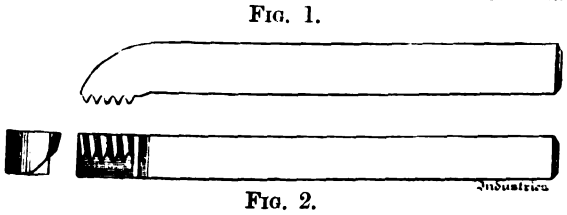

FIG. 2.

the "hob," had to be cut. The piece of steel is forced by means of the slide rest against the tap until a full thread is cut on the end of the piece under operation. The chaser is then removed from the slide rest and attached to a long wooden handle, and pressed by hand against the hob until the thread is straight, and has obtained sufficient rake as shown in Fig. 3. This is rather a slow and laborious operation; but with this kind of hob it is the only means of removing the curvature at the end of the chaser, and of making a proper cutting tool of it. With this method of production the expenditure of time is large, and an expensive lathe is used which might be more advantageously employed. Hobs of larger diameter, made specially for cutting chasers, have been used in place of the plug master tap. The diameter of such hobs, being from three to four times that of the tap, the number of grooves and cutting edges is increased. But, as the diameter increases, the inclination of the thread accordingly decreases, and trouble is experienced when using the chasers, owing to the want of sufficient clearance between the thread on the chaser and that traced on the rod. This difficulty might have

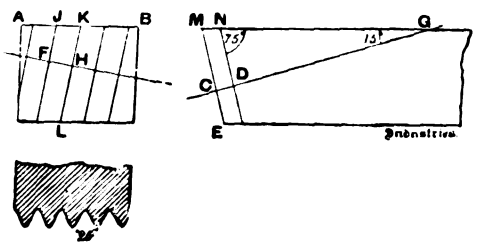

FIG. 3.

been overcome by backing off the bottom edge of the chaser, but even then the angle of the thread would not be correct; and, considering the amount of trouble and expense involved in making a good hob of large diameter, besides the disadvantages mentioned, their use has been almost discontinued.

MACHINE FOR CUTTING CHASERS.—This machine is specially designed to avoid the process of straightening the ends of chasers in a lathe by hand, while securing the advantages of the large thread surface, the numerous cutting edges of a large sized hob, and of cutting the thread on the end of the chaser at the proper angle. The machine is similar to a small milling machine, the hobs being keyed on to the spindle, while the chasers are held in a slide rest at such an angle as to give the thread the right inclination, and to back off the bottom edge at one operation. The hob, instead of having a screw thread cut on its surface, is provided with a number of annular grooves, the angle between them and the pitch being arranged in such a manner that the chaser cut by the hob will produce a thread of the required pitch and angle. Fig. 3 shows a chaser in three different views. The cutting edge of the chaser is along the line M N and A B, and this line must be exactly level with the lathe centre when using the chaser. The outline of the cutting edge should, in plan, have the required pitch, and the thread should have the exact angle. Suppose the thread be ·25in. pitch and the angle of thread be 55°, then the depth of thread is ·64 × ·25 = ·16in. = MN. Then draw C D at right angles to the thread M E, and passing through the centre of the annular hob used for cutting this chaser: CD is then equal to the depth of the annular grooves on the hob. CD = MN cos ∠ CGM, and ∠ CGM is, in this case, 15°, consequently we find that CD = MN cos 15°. Now, cos 15° = ·9659, consequently the depth of the annular grooves on the hob must not be ·16in., but ·16 × ·9659 = ·1544in. if the chaser is intended to cut a thread ·16in. deep. The pitch of the thread on the cutting edge of the chaser J K = ·25in. Let F H, which is at right angles to the thread K L, represent the centre line of the hob, then F H is the pitch of the grooves on the hob; the difference between F H and J K being almost inappreciable for large chasers; but for the smaller sizes, however, it should be considered. For instance, in a ¼in. screw with twenty threads per inch, the pitch is ·05in. and the circumference of the bolt ·7854in., then

$$\frac{1}{FH} = \frac{\sqrt{\cdot 7854^2 + \cdot 05^2}}{\cdot 05 \times \cdot 7854} = \frac{1}{\cdot 0499}$$

consequently the pitch of the grooves on the hob must be $\frac{1}{1\,0\,0\,0}$in. less than the thread to be cut; and if this is not allowed for in making the hob, the error in one inch length of the screw cut would amount to $\frac{1}{3\,0\,0}$in., which is about the thickness of an ordinary sheet of tin foil. This difference may be of little practical consequence; but, when making such costly standards as these hobs are, no effort should be spared to make them as accurate as possible. Similarly, the angle of the thread on the hob is slightly different to that cut by the chaser, owing to the inclination of the thread on the end of the chaser.

Proceeding now to consider the making of the hobs, the first step in this direction is the choice of the steel and its treatment. As regards the quality of steel which is most suitable for this, or, in fact, for any other kind of tools, the tool maker cannot do better than make his wants known to the firm from which he buys his steel, as there are many details and intricacies in the manufacture of tool steel, which only those engaged in the trade know. Moreover, he is more likely to make good tools which will not split or warp in hardening, if the steel maker knows, when melting the steel, what shape the finished tool will have, and what work it has to do. When the hob is forged, the outer portion of the metal is unavoidably hardened by hammering, and is in a state of irregular tension. If the hob be cut when the steel is in this condition, it will be almost certain to warp or crack in hardening, and thus cause annoyance and expense which might have been avoided by taking the precaution to carefully anneal the steel after forging, and thus relieve the initial tension of the outer portions, and remove all internal strains. The annealing is a very simple operation, consisting in raising the steel to a cherry red heat, and cooling it slowly. The hob should then be carefully bored and fitted to its own spindle; then it is turned, and annular rings of the form and pitch required cut on its surface. This is an operation requiring great care, as

Digitized by Google

TURNER'S IMPROVED STEAM ENGINE.

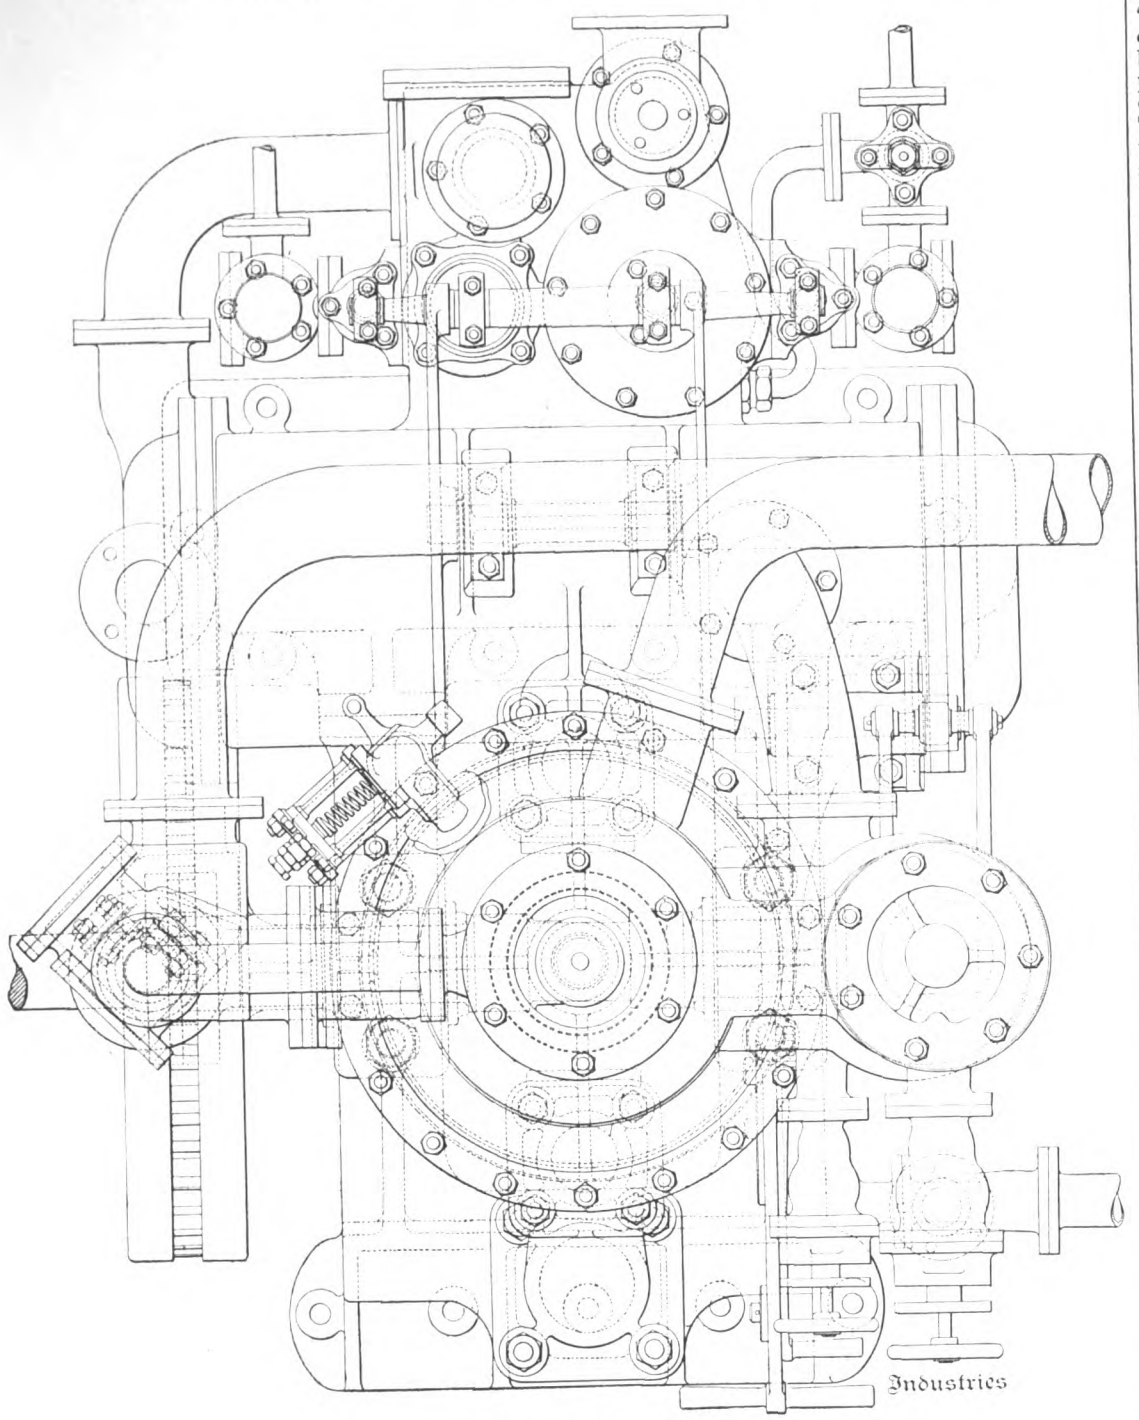

FIG. 2.—GENERAL PLAN.

all the threads must be of precisely the same form and pitch. When this is done, shallow grooves are cut parallel to the axis of the hob, about $\frac{5}{32}$in. to $\frac{1}{4}$in. pitch to form the cutting edges, and the hob is then ready for hardening—the most difficult operation of all. For that purpose the hob is placed in an iron box, and crushed charcoal carefully placed all round it to protect the threads from air contact and prevent scaling; the lid is then put on and carefully luted round with clay, and the box is then heated to the lowest temperature at which the steel will harden—as found by experiment. If heated too much, the danger of water cracking is increased, even though the heat may not be sufficient to spoil the steel. The next point for consideration is the cooling of the hob. Water warmed to from 80° to 100°F. is the best for tools of simple form, but for more complicated shapes a mixture of soft soap and water heated to about 100°F. is preferable, the soap having been boiled with the water until it is almost as thick as cream. Into this the hob is lowered in a perfectly horizontal position. It is not advisable to lay it on a plate for this purpose, or even to thread it on a rod with a plate riveted on the bottom, as the under side would be prevented from cooling as quickly as the upper one, and the circulation of water through the hole would be stopped. A better plan is to pass the hob over, or suspend it from a wire rod having three horizontal arms at its lower end to receive it. The hob must not be removed until it has assumed the same temperature as the bath, and whilst immersed it must not be moved sideways to hasten cooling. The soap solution has been used for many years, and is generally well known; but it is the safest bath for hardening tools such as hobs, milling cutters, riveter's snaps, &c., as by its adoption water cracking is largely prevented. A riveter's snap, for instance, will almost always crack at A A (Fig. 4) when hardened in warm water; but very

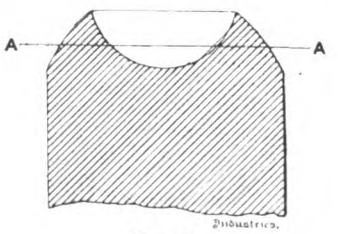

FIG. 4.

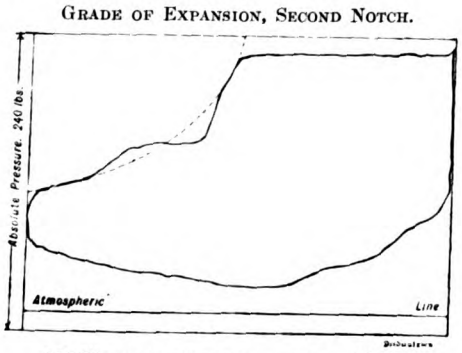
rarely when using the soap bath. After solid steel hobs and milling cutters have been hardened and tempered, it has been observed that they frequently slightly change in form for several days afterwards, and sometimes even break into several pieces without any apparent cause. This is, in some cases, the fault of the steel; but generally it is due to internal stress, originated in the metal whilst being hardened. The utmost care should therefore be taken in performing that operation; and when tempered, the hobs should be allowed to stand for a few days before being finished. The hole is then "lapped" out with a copper lap, and the threads examined to see if they are true. Frequently they will be slightly eccentric, and besides this, they will have probably warped sideways; and sometimes to such an extent that a good chaser could not be cut with them. To remedy this defect, a copper lap is made to fit the threads, and each one is ground true separately. Considering these difficulties, it is not surprising that other ways of making hobs have been tried. The idea was conceived of making a hob not wholly of steel, but of a face attached or welded to a centre of soft iron or very mild steel; and ultimately the difficulty of warping and cracking was avoided by forging a wrought iron centre, about 1in. less in diameter than the finished size of the hob, and welding a ring of steel about $\frac{5}{8}$in. thick on to it. The hob was then turned, the annular grooves cut, and the cutting edges formed; but the hole in the centre was not bored until after the hob had been hardened and tempered. It was then centered as truly as possible in the lathe, and bored out to fit the spindle. In this way the difficulty of water cracking was entirely avoided, and the threads needed no grinding afterwards.

TURNER'S IMPROVED STEAM ENGINE AND BOILER.

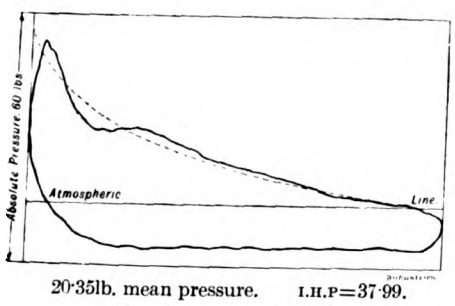
WE illustrate on this and adjacent pages, an engine and boiler, designed and patented by Mr. Henry Turner, 8, Chapel-street North, Liverpool, which together possess several important and novel features. One important feature in the engine is in the arrangement of the valves, by means of which the cylinders are used alternately for steam pressure, and for forcing air into the closed furnace of the boiler; and as the air is drawn round the tubes of a heater in the uptake, two objects are gained: (1) The heated air raises the temperature of the cylinder equal to or greater than that of the incoming steam; and (2) an automatic forced draught is created. In the engine illustrated, only one pair of cylinders is shown; but it is proposed to use two, three, or more pairs for large steamers, each pair working on a separate crank. The high pressure cylinder is placed on the top of the low pressure cylinder, the two pistons being coupled and working one crank. The steam after having acted in the upstroke of the high pressure cylinder passes direct through the valve box O to act on the downstroke of the low pressure cylinder, thus acting only on one side of each piston, the vacuum acting only on the top side of the low pressure piston. In the opposite strokes, heated air is drawn from D (Fig. 1) to the top side of the high pressure and to the bottom side of the low pressure pistons, and forced into the furnace of the boiler. The high pressure cylinder is 6in. diam. and $10\frac{1}{2}$in. stroke, the low pressure cylinder being $17\frac{1}{2}$in. diam., with the same stroke. The difference of the two diameters will, no doubt, appear very great; but while the vacuum is acting on the low pressure piston (as shown on the diagram, Fig. 4) it will be seen that the high pressure steam is forcing up the high pressure piston—the downward stroke being due to expansion. If the vacuum, therefore, be deducted from the low pressure diagram, and added to the high pressure diagram, it will be found that the pressures in each stroke only vary an amount necessary to overcome the weight of pistons, &c., to be raised in the upstroke. The valve chest H may be constructed in one with the chamber E, which connects the two cylinders, or separately, according to the size of the engines. H_1 is the steam port to the high pressure cylinder, H_2 to the low pressure, D being the exhaust leading to the condenser. The valve is of the piston valve type, and consists of two metallic packed valves M M^1 combined in one with the spindle T, and actuated by the link motion. The valve chest H has an annular steam passage U communicating with the stop valve C. The circular liner R has a number of triangular shaped ports R^1 R^2 R^3 R^4 opening into the belt U and to the exhaust D. The valve has three circumferential grooves N P Q, the groove N communicating the port R^1 to the steam belt U and the port R^2 to the steam passage H^1; the groove P communicates the port R_2 and the central passage V in the valve, by which the steam is led to the bottom of the valve M^1, and enters the port R^4 as it uncovers and passes through H_2 to the low pressure cylinder; the groove Q opens the port R^3, allowing the exhaust to pass from the low pressure cylinder to the condenser through D. The piston rings, or valve surfaces, are shown at S S^1 S^2 S^3. The piston S acts as a balance valve only; piston S^1 is for the admission and exhaust of steam in the high pressure cylinder, having a large amount of lap to insure an early cut-off; piston S^2 forms a division between the high and low pressure exhaust; piston S^3 is for the admission and exhaust of steam in the low pressure cylinder, being provided with a



Digitized by Google

late cut-off. The small amount of advance in the eccentrics required for the valve S^2, and the large amount required for the valve S^3 to obtain the early and late cut-off, is accomplished by means of the links W, which are attached to the lower side of the eccentric clips, and give the necessary variation in the movement of the link motion. The hot air chamber O consists of a vessel containing four sub-chambers, which communicate in due order by means of metallic valves with the atmospheric side of the piston and the furnace of the boiler.

The boiler consists of a cylindrical shell with a tapered flue and a nest of return tubes; these tubes are shown at the side of the flue in the drawing, but for large boilers they would be placed at the top, as in an ordinary marine boiler. The crown of the fire box has a fire clay—or other refractory material—lining, with an air space between it and the plates, in communication by means of the pipe F with the air pipe G from the valve chest O. In the uptake is fixed an air heater D, fitted with vertical tubes through which the waste gases are conveyed to the funnel; diaphragms are placed at intervals as shown, to deflect the incoming air and so absorb as much heat as possible from the tubes. The pipe F which connects the air pipe G with the air casing of the fire box is fitted with a double seated valve A in the valve box B, by means of which the air may be shut off from the furnace and led either to the funnel direct or to the waste pipe H. With a single flued boiler similar to the one illustrated, this operation is necessary each time of firing up; but with more furnaces the draught can be directed to those with the doors closed.



We understand that trials of many hours duration have been made with the engine described, with excellent results. These are shown by the following indicator diagrams (Figs. 3 and 4), and the tabulated data and results accompanying them. A powerful brake was attached to regulate the revolutions of the engine, and when the above diagrams were taken the stop valve was only half open. With the same brake load applied, the stop valve was opened fully, and the number of revolutions was increased to 480 per minute—equal to a piston speed of 840ft. per minute; with this high speed the boiler maintained, or rather gained upon, the normal working pressure. After a careful measurement of the coal, the designer states that the consumption was found less than 1lb. per i.h.p. per hour, which is an extremely low consumption.

GRADE OF EXPANSION, SECOND NOTCH.

129·9lb. mean pressure. I.H.P=26·86.

FIG. 3.—H.P. CYLINDER.

20·35lb. mean pressure. I.H.P=37·99.

FIG. 4.—L.P. CYLINDER.

TOTAL I.H.P.=64·85.

GENERAL PARTICULARS.

Diameter of high pressure cylinder (single acting)	6in.
Diameter of low pressure cylinder " "	17½in.
Ratio of areas	1 to 9
Total effective heating surface	88 sq. ft.
Total effective grate surface	2·92 sq. ft.
Steam pressure	222lb.
Vacuum	25in.
Revolutions	308
Heating surface per i.h.p.	1·35
Grate surface per i.h.p.	0·03
I.H.P per square foot of grate	22·26
Temperature in uptake	275°

Arrangements have been made for fitting this engine into a boat; and it will be interesting to note its performance during a long run at sea. The engine and boiler we now illustrate were made by Messrs. G. Bayliff and Sons, Wirral Foundry, Birkenhead.

FOREIGN INDUSTRIES.

(From our own Correspondents.)

PARIS, 5TH JUNE, 1888.

THE IMPORT COAL TRADE.—The manifest tendency towards shrinkage in the import coal trade is a consequence, and in some degree a measure, of the steady development of the native mining industry. From the Customs returns, it appears that the deliveries of foreign coal for consumption in France amounted, for the first four months of the current year, to 2,658,084 tons, against 2,787,360 tons in the corresponding period of 1887. The decrease is mainly in the trade with Belgium. Of the quantity received this year, England furnished 45·34 per cent., Belgium 46·14 per cent., and Germany 8·47 per cent. The declared value of this imported coal was £1,586,600, against £1,821,520 last year. In 1882, the value reached £2,297,160. The average for the first four months of the last ten years is £1,905,840. The imports of coke, most of which is derived from Belgium, amounted to 340,641 tons, against 325,750 tons last year. The effects of the competition of the home industry are seen in the lower prices paid for foreign coke. Though the volume of the imports has increased 4½ per cent., the declared value is 21½ per cent. less, notwithstanding the fact that coke has for some time past been steadily advancing in price in all markets not open to foreign competition.

THE IRON MARKET.—The iron trade is beginning to feel the weaking influence of the disturbed state of the political atmosphere. Consumers hesitate and seem disposed to delay their purchases till the latest possible date. In Paris, business has for the moment shrunk within very narrow limits. Reports, however, received from the several centres of the iron industry state that though the markets are less animated there is still a brisk current of business, and prices outside Paris remain remarkably firm. Great activity prevails in the foundries, the produce of which is likely to advance in price shortly. The old stocks of pig are nearly exhausted, and as they cannot be replenished except at a considerable advance on former prices, founders will be compelled to increase their rates.

THE METAL MARKET.—The copper market retains the same features which have characterised it for some time past. The supply exceeds the demand, which has been greatly diminished by the high prices fixed by the syndicate, and as production is being pushed to the utmost, stocks continue to increase. To maintain its position, the syndicate is compelled to buy the surplus. Strong as the combination undoubtedly is, it must give way to the inexorable law of demand and supply. How soon the inevitable collapse will come is not easy to predict, but the event cannot be far distant. Consumers may expect the same tactics which were resorted to in the case of tin; that is, the syndicate will seek when the time comes to cover its losses by "bearing" the market. Business is growing animated in tin. Lead is dull. Spelter is in good demand, and prices remain at last week's level.

THE SUGAR BOUNTIES.—I have persistently held the opinion, founded on evidence not lightly to be set aside, that the French Government will not consent to the abolition of the bounties system. The facts as they appear on this side of the Channel are wholly opposed to the statements so freely and apparently so authoritatively made in England, to the effect that the proposals of the British Government have already been agreed to. Take, for example, the latest of these facts. At Laon Messrs. Floquet and Locroy have received a deputation from the syndicate of sugar manufacturers, and at the interview M. Mazurier, president of the syndicate, pointed out, and brought forward evidence in proof of his contention, that the abolition of the system of bounties would ruin the French sugar industry. M. Floquet is reported to have acknowledged the justice of the sugar makers' complaint, and he further assured the deputation that the plenipotentiaries sent by his Government to London had received instructions of a nature to safeguard the national interests. It would be interesting to know what these instructions were.

POPULATION RETURNS.—According to a return which has been published by the Statistical Bureau of the Paris Municipality, the total population of the department of the Seine at the end of 1886 was 2,961,089, of whom 2,344,450 lived in Paris. The population of the department has quadrupled since the beginning of the century, and shows an increase of 600,000 in the last ten years.

BERLIN, 4TH JUNE, 1888.

THE COAL MARKET.—Considerable quantities of lignite are being imported from Bohemia by barges down the Elbe, and the output of the Upper Silesian collieries finds also a more ready sale than was the case a few weeks ago. The report of the Dortmund Association of Coking Coal Owners and Manufacturers of Coke, shows considerable and increasing activity during the first quarter of the year. The sales of the association during that period amounted to 325,989 tons of coking coal and 615,140 tons of coke, as compared with 304,287 tons and 522,356 tons respectively sold during the same period of last year. The sales of coke by makers not belonging to the association amounted to 166,011 tons. Of the total quantities sold in the district, 32 per cent. was for Luxembourg, Lorrain, and France.

THE IRON MARKET.—The general tendency of the market is not so buoyant as it was a fortnight ago. It seems as though the depressed condition of the English market had produced the change, but there are also other influences at work. The high prices maintained by the various syndicates make it very difficult for German engineering works to get orders for export in competition with their foreign rivals, and even the home trade in steel rails is seriously threatened by the lower prices offered by English rail makers. In view of this state of the market, the proposal to re-constitute the international convention of rail makers is naturally received with much satisfaction by our rolling mill owners. It is also hoped that French mills will join the convention, if the English, German, and Belgian rail makers can come to an agreement. It is curious to note that whilst in this particular instance the policy of syndicating the trade is gaining ground, the same policy is losing ground in the wire nail trade. The Westphalian nail makers have definitively refused to join the syndicate of German wire nail makers, and in consequence of this opposition, the collapse of the latter is not improbable. The crude iron trade in Upper Silesia remains unchanged. Forge pig is quoted from 50s. to 54s., and foundry pig from 56s. to 58s. for medium, and 61s. for the best quality. Merchant bars are readily taken at 140s. to 142s., special sections 155s. to 157s.

SEWING COTTON.—The competition of English sewing cotton manufacturers has during the last five years been severely felt in Southern Germany. Recently, however, the sale of the English article has considerably decreased in consequence of the low prices obtainable, and our manufacturers are now doing a larger trade than they have been doing for the last five years. With the present depressed prices the profits are, however, by no means satisfactory.

TEXTILES.—The general tone of the Berlin market is quiet, as at present manufacturers have considerable stocks of raw materials to work up. The prices obtained for ready made goods show no improvement. A few parcels of French wool have been bought by commission houses here. The demand for worsted yarn is somewhat weaker, but prices have nevertheless slightly advanced. The rates for carded yarn have also been raised, and this step has called forth a protest on the part of manufacturers. Shoddy yarn is offered very cheaply, and cotton yarn is quiet. Business in piece goods is almost at a standstill, but fancy articles and hosiery goods are in good request.

PORTLAND CEMENT.—Tenders have recently been invited in Bremen for the supply of 1400 tons of Portland cement, to be used in works in the district of the Bremen free port. Twelve offers have been received, but the contract has not yet been given out. The prices quoted ranged between 40s. 4d. and 46s. 10d. per ton. Pozzuolana cement was offered at from 31s. 11d. to 35s. 6d. per ton. The contract will be settled in about ten days.

HOPS.—Reports from the province of Posen state that there is little demand for any but the best qualities of hops on the part of home breweries, and that the prices of the small lots sold are in favour of buyers. In medium qualities there is very little doing, and inferior kinds can hardly be sold at all. Present prices are 70s. for best qualities, medium sorts at from 35s. to 40s., and inferior qualities at from 12s. to 20s.

VIENNA, 4TH JUNE, 1888.

THE IRON MARKET.—Although prices are as yet fully maintained, the condition of the iron market during the past week cannot be described as buoyant. Owing to the dry season merchants are beginning to fear that the harvest will not be so good as was hoped a few weeks ago, and consequently the demand for agricultural machinery will fall short of previous expectations. As regards building iron, the season may also be considered as practically near its close. The greater portion of the iron required for building purposes has already been contracted for, and no transactions of any importance can be expected to take place after this month. In crude iron the firmer prices are fully maintained, and business in merchant bars and sheets remains normal. As yet engineering works are fully occupied, and rolling mills have even an abundance of orders on their books. This is mainly due to the somewhat more vigorous condition of railway enterprise, large quantities of rails being required for renewals, new lines, or duplication of old lines. Business in Hungary is fairly satisfactory, especially as regards the larger works, but smaller works are rather short of orders. There is still a good demand for building iron, but it is not expected that this will last much longer. In rails, and especially those of small section, business is very brisk, and prices have a rising tendency. The balance sheet of the Alpine Mining Company, which has just been issued, shows that the output of the works during 1887 was slightly larger as compared with that of the previous year. There were in work 591 coal pits, 61 iron ore pits, and 11 manganese ore pits. The total production in round figures was 324,000 tons of coal and 229,000 tons of iron ore. The total quantity of crude iron produced was 75,000 tons, and of steel in various forms 32,000 tons.

PETROLEUM.—A short time ago the Austrian petroleum refiners formed a syndicate, with a view to prevent the excessive cutting down of prices, as there was some danger of it taking place in this industry like in many others. According to the rules of the syndicate, no member is allowed to sell petroleum under 6fl. 50kr. per barrel. In connection with this syndicate is also the formation of a company which is now building a large warehouse for refined petroleum, at a suburban station of the Southern Railway, in the neighbourhood of Vienna. The warehouse will be divided into sections, each rented by one of the large petroleum dealers of Vienna. The petroleum refineries of Kronstadt, in Transylvania, which have hitherto worked up Roumanian oil, have been bought by the Fiume Petroleum Company, whose intention is to discontinue using Roumanian oil, and to treat at Kronstadt only Russian oils carried by the company in tank steamers and tank waggons *viâ* Fiume.

THE JUBILEE EXHIBITION.—As a general rule, exhibitions in recent years have become huge organisations for advertisement and business purposes; but the present Jubilee Exhibition, although not quite free from this reproach, is a more representative show of Austrian industries than many of its predecessors, and as such it is likely to be very successful. The collections of art metal work, carpets, furniture, glass, pottery, leather goods, trimmings, and other articles of a semi-artistic character, are very complete, and give the visitor a fair idea of the general state of these industries in Austria at the present time. The paper makers in this country have come forward with good collections of their wares, and their trophy, which is a tower placed in the centre of the Rotunda, and reaching nearly to the top, is a very attractive object. The engineering trades are also well represented, especially as regards high speed engines for electric lighting. There will be found three-cylinder engines, high speed double acting engines, small marine engines, a new benzine motor of Langen & Wolf, and the petroleum engine of Marcus. The latter is coming into favour in Vienna, because it can be worked with any kind of common petroleum. The design is compact and simple, and the workmanship very creditable. The igniting apparatus works with perfect certainty. Amongst the steam dynamos a 150 h.p. alternator, constructed by Ganz & Co., deserves special mention. The cylinder of the engine is 15¾in. diam. by 18in. stroke, and the speed is 250 revolutions a minute. The steam is distributed by a piston valve, and the cut-off is controlled by varying the angular position of the eccentric by a centrifugal governor mounted direct on the crank shaft. The dynamo is self exciting and self regulating. Of the belt driven dynamos, those exhibited by Messrs. Egger are fair representatives of modern electrical engineering. Two kinds are employed, viz., arc and glow light machines. Those for supplying glow lamps have an output of 300 ampères at 110 volts pressure, when driven at 600 revolutions per minute, the armature has a resistance of ·015 ohm, and the field, which is plain shunt wound, has a resistance of 19·466 ohms. The armature conductor is a copper tape, and the density of current in it is about 2000 ampères per square inch. The other type of machine used for arc lighting in parallel has an output of 450 ampères at 70 volts pressure, when the machine is driven at 500 revolutions per minute. The weight of these machines is 2 tons 16cwt.

BRUSSELS, 5TH JUNE, 1888.

THE METAL MARKET.—There is no change in the course of affairs, and prices remain very firm. The great pressure which has existed on account of the scarcity of pig may be gathered from the fact that whilst the imports of foreign pig in March, 1886, amounted to 14,000 tons, and in March, 1887, to 20,000 tons, they increased in the same month of the current year to 40,000 tons. Most of them came from England, about 10,000 tons being shipped direct to Belgian ports, and 15,000 tons *viâ* Holland. In view of the small demand from abroad it is a little doubtful whether the rise in the price of merchant iron fixed by the syndicate will prove of benefit, as it may serve to prevent orders being given out.

THE FLAX MARKET.—There has been remarkable activity in the flax market, buyers being eager to do business owing to the bad reports on the present season's crop, which is likely to prove insufficient unless there is a speedy change in the weather. Owing to absence of rain, the plants do not promise at all well at present.

SUGAR.—The market is very quiet, and notwithstanding the fact that in most other European markets there has been a rise, no change in price has taken place here. For home consumption, refined sugar finds a good sale; but the export has decreased.

THE EXHIBITION.—It is to be hoped that our Exhibition will be completed some day; in the meantime, it is being opened in instalments, and on Sunday the Italian section was inaugurated. The usual banquet took place, at which the Italian Minister, the Belgian Premier, and Count Mirafiore, the Italian Commissioner, were present.

ELECTRIC LIGHTING.—Important alterations are to be made in the installation at the Theâtre de la Monnaie, which has not been found quite satisfactory. The municipality will be concerned in the matter, the electric lighting section being placed in the hands of their engineer, M. Wybauw. The long distance system will be employed, the central station being at the town gas works. Owing, however, to the number of rival systems of transformers in the market it will probably be some time before a final selection is made.—Somzée accumulators are finding a very good sale for private house lighting, and they are also being used for part of the electric lighting of the Exhibition.

GAS LIGHTING.—Great progress is being made in the employment of regenerative gas burners in this country, especially in Liège, Ghent, Antwerp, and Brussels. The Wenham Company are doing such good business that it is difficult to obtain lamps from them for immediate delivery. Other inventors are also in the field, and the Fourneyse and Delhaise lamps both find favour. The Compagnie

Digitized by Google

Franco-Belge of Anderlecht are finding a very ready sale for their Ezmos lamp, which gives a clear white light of great steadiness, and which has also the advantage of being comparatively small.

DÜSSELDORF, 4TH JUNE, 1888.

THE IRON MARKET.—A calm has come over the iron market, the result probably of the depression in England, as in the present relations the movement of the English market is at once and strongly reflected in that of Western Germany. Compared with last week, business in crude iron is dull. The demand is light for spiegel, and only moderately brisk for forge. The former may now be bought for 58s. for the 12 per cent. quality; the latter has oscillated in price between 50s. 6d. and 51s. 6d. There is a steady demand for Luxemburg forge at 38s. 9d. Bessemer and Thomas pig are less inquired after; foundry pig, however, is in brisk demand. The finished iron market is but little changed. Bars are not much inquired after for home consumption, while the export trade is utterly lifeless. With the present prices of the raw materials, there can be no thought of successful competition in neutral markets with Belgian and English goods. Manufacturers sell bars at a loss to the makers of machines for export, to enable the latter to meet foreign competition. Business in plates continues brisk. Boiler plates are likely to advance in price. The spring trade in sheets is disappointing, the expected revival failing to make its appearance. Prices of Siegen sheets are, however, firmly maintained at £7. 10s. to £7. 12s. Wire shows no improvement, as the impending collapse of the wire nail syndicate has checked for the moment the business in nails. Foreign competition keeps the rail trade in a depressed state.

THE HARDWARE AND OTHER SMALL GOODS TRADES.—The hardware and other small goods manufacturers of this locality have this year done a brisk spring trade, and are still very busy with orders on hand. Agricultural implements sell freely. The hay and dung fork makers' syndicate has been renewed. The coal shovel makers' syndicate has agreed to increase its prices from the 1st inst. The wrought iron saucepan makers' syndicate has fixed its prices at 20s. per cwt. All these associations have held meetings within the last week. At Solingen great activity prevails in the works for the manufacture of swords and bayonets.

THE MINING INDUSTRY.—The revived and constantly growing demand for coal has infused life into the coal mining industry of Western Germany. All collieries are now being worked full time, a circumstance unusual at this season of the year. In some cases the output has been sold to the end of the current year. Iron ore mining, too, is being prosecuted with vigour. From a report of the Minister of Public Works just issued, we learn that the total production of the Prussian mines of all classes increased from 47,000,000 tons in 1877, to 74,000,000 tons in 1887. This increase has taken place chiefly in coal and ironstone mining.

EXTENSION OF THE INLAND WATERWAYS.—All the industrial towns of Westphalia and the Lower Rhine have been in a state of festivity to celebrate the passing of the measure involving the construction of the Ems Canal by the Reichstag. This event is of the highest importance to the industry of Western Germany, especially to the coal and iron trades; and it is, moreover, one which will have an important bearing upon British trade. It is confidently expected that this waterway will enable the manufacturers of this locality to more successfully oppose English competition, not only at home, but also in neutral markets.

LILLE, 5TH JUNE, 1888.

TEXTILE MANUFACTURES.—The political event of the week, the Hungarian Minister's speech relative to the participation of Hungarian manufacturers in the Great Exhibition of next year, has increased in a notable degree the feeling of distrust which pervades the industrial world. Under such circumstances it is vain to look for improving trade. Last week's business shows the evil influence of the disturbed state of affairs. The markets generally are lifeless, and the prospect of more remunerative prices grows more and more remote. The linen goods trade has, however, shown greater activity within the last few days; but this renewed life is the result of numerous small purchases rather than of more important dealings. At Roubaix, the manufacturers are buying wool more freely, and prices show an upward tendency. The greater activity in the market for woollen stuffs, which I reported last week, is well maintained. Had no fresh political complications occurred, I should probably have had to mention a further improvement. It is now announced that the projected wool market for Roubaix has been definitively organised, and will open in July. Doubtless this will serve to promote the trade of the district. Business in cotton goods is dull. An official document recently published states that the steam power applied in France to the production of textile goods increased in the interval between 1876 and 1886 from 85,000 h.p. to 147,000 h.p.

FLAX AND YARN MARKETS.—The week has been one of considerable excitement in the flax and yarn markets. Spinners have eagerly bought up every lot of home grown flax offered, at only a small advance on the previous week's prices; but only a small quantity has been offered for sale, and in most cases holders have asked for a substantial advance in price. In the yarn market there has been still greater animation. Weavers have bought largely, in most cases at the prices of the preceding week, but in several instances at a slight advance on those rates. The bulk of the business was, however, transacted by merchants, who have dealt on a speculative account. The cause of this sudden animation is the state of the new crop. The absence of rain, together with the long spell of north-east wind, has, it is said, occasioned serious injury. Nothing more than an average crop is now possible, and it seems likely to fall much below the average. A large acreage is this year under flax in this district, for in many cases flax has been grown in the place of wheat; but notwithstanding this fact, which for a time kept the flax market dull, the production of 1888 is not likely to exceed that of 1887. At present the plant is very short, and the only hope of improvement lies in speedy and abundant rain.

THE IRON MARKET.—The iron market presents no new features. There is a steady current of business; but partly on account of the uncertainty of the political future, which weighs heavily on all industries, and partly on account of the ill feeling existing between our manufacturers and the merchants of Paris, there is wanting that buoyancy which is indicative of vigorous life. Prices are firmly maintained all round. Bars are quoted £5. 8s. to £5. 12s.; joists £5 to £5. 4s.: common plates £6. 12s. to £6. 16s.; and boiler plates £7. 8s. to £7. 12s.

AGRICULTURE IN THE NORD.—The Department of the Nord contains 1,404,390 acres of cultivatable land, about one-fourth of which is annually put under wheat. The yield of this land amounts, on an average, to nearly 9½ million bushels, a larger quantity than is produced by any other department of France. Oats are also grown in large quantities, amounting on an average to some 3¾ million bushels. The sugar beet covers some 36,000 acres, and large tracts of land are sown with flax and hemp. Hops and tobacco are also important objects of culture.

WINTERTHUR, 4TH JUNE, 1888.

INDUSTRIAL ESTABLISHMENTS.—A limited company has been formed under the title of the Société Zuricoise pour la Construction de Métiers à Tisser, with a fully paid-up capital of £2,400, to work the Wassermann-Haggenmacher patents for weaving looms. The engineering firm of Socin and Wick has been turned into a company under the title of the Maschinenbaugesellschaft Basel. Among the directors is the well known electrician, Herr Emil Bürgin. A new leather works on the Dongola system has been established at Wallenstadt. According to official statistics there are now 3687 factories in Switzerland, employing 150,702 hands.

VENTILATION OF WORK ROOMS.—With a view to determine whether the work rooms in mills and factories were sufficiently well ventilated, Dr. Schuler, one of the Swiss factory inspectors, has visited 130 establishments in this country. Samples of air were taken in each of these, and the following shows the quantity of carbonic acid contained:—

	Carbonic acid. Per cent.
In one sizing mill the air contained	·4
In four carding mills the average was	·68
In twenty-seven cotton spinning mills	·69
In five cotton twisting mills	·79
In six foundries and machine shops	1·24
In four calico printing works	1·35
In twenty-one cotton weaving mills	1·37
In thirty-six embroidery factories	1·63
In nine printing establishments	1·73
In sixteen silk winding and weaving mills	2·21

In order to reduce the quantity of carbonic acid contained in work rooms, Dr. Schuler proposes, where no ventilating appliances are at present employed, to make use of the double windows for this purpose by substituting a perforated sheet of metal for one of the panes of glass. By this means he considers that by the great difference of temperature between the interior and exterior of work rooms a sufficient current of air will be produced. Trials made with such a ventilator have shown that the speed of the air through the holes varied from ·633m. per second at a temperature difference of 17°C. to ·725m. per second at a temperature difference of 24°C.

MADRID, 4TH JUNE, 1888.

ELECTRIC LIGHTING.—With reference to the electric lighting of La Comedia Theatre, to which I recently referred, an injunction has been obtained by the neighbouring tenants on account of the noise. This proves what I have said on previous occasions, that there is an opening in Madrid for a large central electric light station, which ought to be profitable, as the price of gas here is 9s. per thousand. The owners of the theatre will probably appeal against the decision, on the plea that they are merely complying with the order respecting the lighting of theatres; but the installation cannot continue as it is, for there is not sufficient space to manage it properly, and it is certainly very noisy.

PETROLEUM.—The Bill raising the duties on petroleum to the extravagant rate of about 1s. 2d. per gallon has passed the Cortes, and although the duty was imposed partly with a view to an immediate increase of receipts, I do not consider this expectation will be fulfilled, as the imports have been so large lately, in anticipation of the increased duties, that there is sufficient supply in the country to cover a year's consumption, which amounts to 40,000 tons.

NEW YORK, 26TH MAY, 1888.

THE COAL MARKET.—Prices in the anthracite coal market are fairly well maintained, but production still exceeds the demand. The official figures for April show that the production for that month was nearly 70,000 tons more than in 1887, and that stocks of coal had increased 267,000 tons at the ports. The Lackawanna shipments have increased 538,000 tons for the year, while Lehigh Valley has fallen off the same amount, and Reading nearly 750,000 tons. This disparity causes considerable ill feeling, and the fact that Lackawanna still refuses to join the coal combination aggravates the matter. Complaints are also made that they are cutting down rates. When the demand for coal springs up, and the real business of the year begins, some arrangement will have to be made. Bituminous coal is quiet, with a slight tendency to lower prices; but the market is not likely to change much at present, as nearly the entire season's production is already contracted for.

THE IRON MARKET.—There is very little change in the condition of the iron market, which is still very dull, and there is no immediate hope of improvement. For about a year the demand has been decreasing, and although large compared with 1885, it is not enough to absorb all the iron offered. The pig iron market is still in an unsettled condition, and concessions even on small lots have been considerable. The Thomas Iron Company have intimated a reduction of $2 per ton; as at first announced, it was supposed that the reduction only amounted to $1, and this was not a surprise, as several of the leading companies had been quoting special rates to their customers until it was generally understood that $1 had been taken off since the first of the month. The reduction of $2 was a sharper cut than the trade were prepared for, and may not be met by other companies until the situation is more fully developed. Prices are now within $1 per ton of the lowest on record, and are $16, $17, and $18 per ton for the three grades; the lowest record, $15 for grey forge and $17 for No. 1 foundry, having been reached during a portion of 1877, 1878, and 1885. There is no probability of an increasing demand even at lower prices, consumers having bought all they want for the present. Business in manufactured iron remains much in the same condition as reported for several weeks past. Prices are kept at a point little, if anything, beyond first cost, even to mills that can run full. Many have shut down entirely, competition making it impossible for them to keep their men employed without cutting prices to a point which would involve serious loss.

THE METAL MARKET.—The copper market opened steady with but very little business, but towards the end of the week prices advanced slightly. There has been a slight improvement in tin, but little business has been done. Tin plates have been closely following pig tin in fluctuations. Stock is not plentiful, and spot commands a premium. The demand is good both for spot and futures. The importation of plates has increased 17 per cent. in the last nine months. The lead market is dull and weak; prices are unchanged, and but little has been sold. The spring trade has been 30 per cent. less than it should have been, and as long as the tariff agitation continues markets will be uncertain.

THE NAVY.—The Secretary of the Navy has approved of the modified plans for the machinery of the "San Francisco," to be constructed at the Union Iron Works in San Francisco. The plans are for triple expansion engines having cylinders 42in., 60in. and 94in. diam. and 36in. stroke, and are to develop 11,000 h.p. The principal parts of the engines are to be of steel, and wherever possible to be interchangeable. The condensing surface is 14,500 sq. ft., and the condenser is fitted with double independent air pumps. Four double ended cylindrical boilers are to be built, having a heating surface of 19,500 sq. ft., and an independent boiler for auxiliary purposes. Forced draught is to be used on the closed ash pit system. The gunboat "Yorktown" and the dynamite boat "Vesuvius" have been launched at Craups. The Richmond Locomotive Works will receive the contract for the engines of the battle ship "Texas," to be built at the Norfolk Navy Yard.

LAGGING FOR LOCOMOTIVE BOILERS.—At the Rhode Island locomotive works a number of new locomotives are being built, and are lagged all over the boiler and dome with a mortar whose principal ingredient is asbestos, making the covering all in one piece. The mixture is put on the boiler while it is under steam, and it takes several days to finish the operation. It is claimed that leaks will show plainly by discolouration, and all that will be needed to make repairs will be to cut out the covering over the leak, and after the repairs are finished to re-plaster the opening in the cover.

PORTABLE ELECTRIC LIGHT PLANT.—The Cumberland Valley Railroad is one of the first to have a travelling electric light car. It was fitted up to furnish light at picnics, camp meetings, and for removing wrecks at night. It is an ordinary box car, but strongly built, and is furnished with an 8½ h.p. engine and boiler, and a 15-light Thomson-Houston arc dynamo. The car carries poles and a reel (containing three miles of insulated wire), 3 tons of coal, and 1000 gallons of water. The car has more than paid for itself in the increased sale of tickets for picnics, &c., and has been hired by most of the connecting roads, from time to time, to be used when clearing away wreckage. It has also given an impetus to the introduction of the electric light in many of the smaller towns along the line of the road.

THE "CYCLONE" PULVERISER.

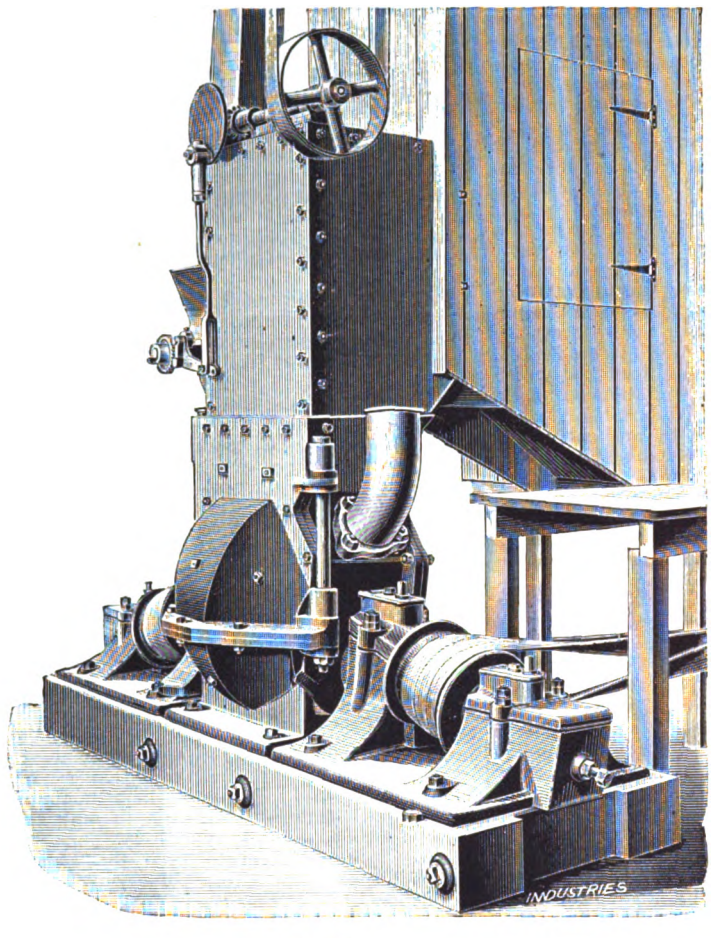

Fig. 1.

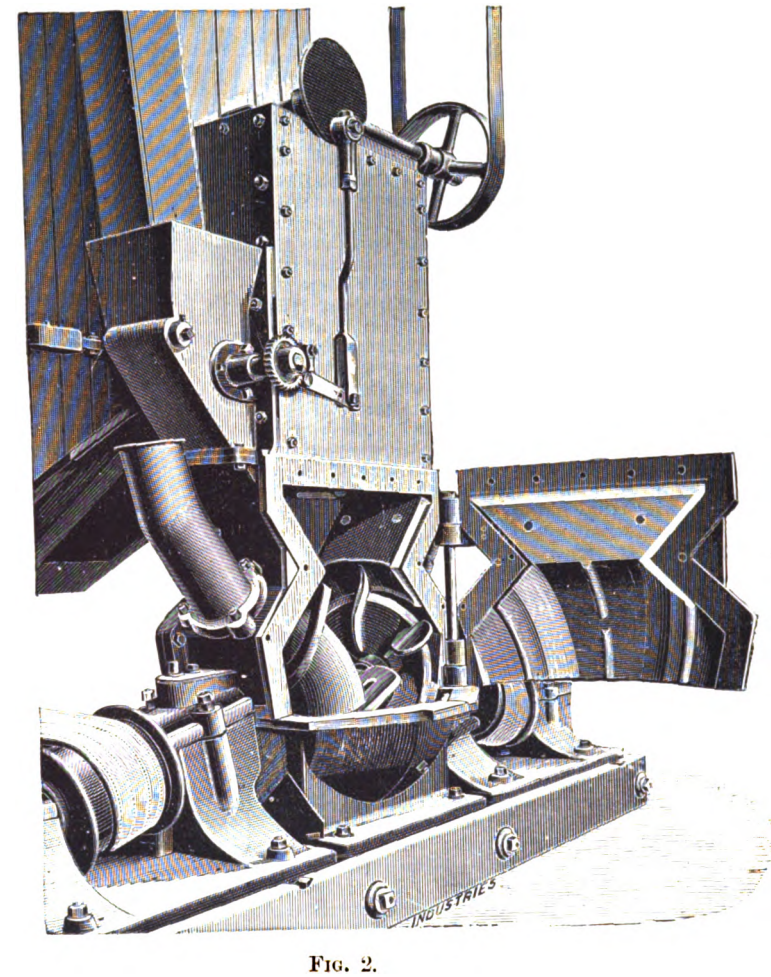

Fig. 2.

THE "CYCLONE" PULVERISER.

When the process of cutting hard surfaces by a sand blast first came into use, it was currently believed that the invention was due to an observation made by an officer of the American Federal army, who noticed that the glass panes in the windows of a cottage exposed to the wind from a sandy shore were blinded by the continual bombardment of sharp sand, and thus a natural and, to the owner of the cottage, certainly a very undesirable phenomenon brought about the development of a most valuable industrial process. Whether the dreaded cyclones which occasionally sweep over the American continent may be similarly credited with having stimulated inventive talent, we are unable to say; but there can be no doubt that a small artificial cyclone, properly applied, produces a marvellous result in the way of reducing the hardest substances to a fine powder. The reduction is due to the rubbing of the material on itself, and this principle has been made use of in the "Cyclone" pulveriser, now being introduced into this country by Messrs. Cowper, McCarnie, & Co., of Fenchurch Avenue, London, E.C. We recently inspected the machine, and also samples produced by it, at the Gun-street Mills, Spitalfields, E., and give herewith some illustrations. Fig. 3 shows the general arrangement of the pulveriser and the depositing chambers, whilst Figs. 1 and 2 are perspective views showing the machine closed and open. The small artificial cyclone is produced by two fans F revolving face to face but in opposite directions. The axes of these fans are slightly inclined to the horizontal, so as to produce an upward component in the air currents by means of which those particles which have been sufficiently reduced are carried off, passing either horizontally along over the receptacles F G, or first up the chimney on the left side and down on the right side of the central partition, after which the powder is deposited in the receptacles F G. If the material is to be deposited immediately after leaving the machine, the slide or shutter C, shown dotted in our sketch, is withdrawn; if the chimney is to be used, this shutter is inserted and one of the shutters E is withdrawn, thus regulating the length of the air column which holds the powder in suspension, and by this means the degree of fineness of the powder is partly determined. From the receptacles the material may be either delivered into sacks as shown at F, or as at G it may be led down a shoot to a lower floor. An exhaust fan K serves to take off any back pressure which might exist above the pulveriser. The material to be treated is fed in at the hopper H, and falls into a receptacle D, in which is a revolving drum with compartments (not shown in our sketch) which discharges at regular intervals a given quantity of the material into the space between the two fans, where it is taken hold of by the vortex of air and held in suspension until, through the attrition of the material against itself, the particles have been sufficiently reduced to be carried off by the upward current of air. The gear by which the feed drum in D is worked, is clearly shown in Figs. 1 and 2. The rate of feed is adjustable, and so is also the supply of air; the latter being regulated by slides in the air inlet pipes A A. At B B there are additional inlets for air, covered by wire gauze to prevent adulteration of the material, which might take place if extraneous matters were sucked into the apparatus through these openings. At first sight it might appear as if the material, upon being fed into the apparatus, would fall to the bottom and block the space where the two fans come closest together; but this is not the case. Upon opening the front door there is hardly any material found at the bottom, and this proves that the material, even when composed of heavy and fairly large pieces, is really held in suspension between the fans by the violent vortex action and upward draught of the air. As a further consequence, the wear on the blades of the fans is comparatively slight. In the machine we saw, the fans are chilled castings, with spoon-shaped blades about 2ft. in diameter over the tips. The fan casing is a cast iron box with chilled liners, and is provided with a door shown open in Fig. 2. The fans are driven by belting at a speed of from 2000 to 2500, and in a smaller size machine 3000, revolutions per minute.

Notwithstanding the great simplicity of the apparatus which we have here described, the means of adjustment for dealing with any material and obtaining reductions to any degree are very efficient. As already mentioned, the feed can be regulated by the gear shown in Figs. 1 and 2. This to a certain extent determines the degree of fineness to which the material is reduced; but a further adjustment is provided by the slides in the inlet air pipes, and by the shutters in the discharge chamber, as already explained. If the slides in the pipes A A be completely closed, all of the air drawn in by the fan blowers enters from below, and the general tendency of the current is upward, thereby producing a rather coarse product. If it be desired to produce a more granular or powder-like product, the inlet slides A are partly opened, thus checking to some extent the upward tendency of the air current, and forcing the material to remain for a longer time under the influence of the vortex currents. To judge from the collection of samples we saw at Gun-street Mills, nothing seems to come amiss to this pulveriser. It reduces with equal facility to granular or fine powder form, coal, plumbago, slag, phosphates, feathers, and even such hard substances as quartz, flint, and zircon, the powder of the latter substance being, as is well known, used in the manufacture of the Welsbach incandescent gas burner. From an official report, submitted by Mr. Richard H. Buel, C.E., of New York, we learn that the pulveriser with 24in. fans requires 17 h.p. when pulverising plumbago at the rate of 1030lb. per hour, and $8\frac{3}{4}$ h.p. when running empty with all the air inlets open. The rise of temperature of the air as it passes through the machine, when reducing plumbago, quartz, and anthracite coal, was from 20°F. to 23°F. A smaller machine having 12in. fans was found to absorb $9\frac{1}{4}$ h.p. when pulverising flinty quartz at the rate of 420lb. an hour. When running empty this machine absorbed $5\frac{1}{4}$ h.p.

THE TESTING OF MATERIALS.

The United States Government have just issued a volume which, if only regarded as a book of reference, possesses great interest for the industrial community. It is a report of the tests of metals and other materials for industrial purposes made with the United States testing machine at Watertown Arsenal, Massachusetts, during the year ended 30th June, 1885. In addition to tests for purely military purposes, steel wire, riveted joints, railway axles, locomotive gear, ropes, cotton cloth, bricks, &c., have also been dealt with, and the results tabulated in a very accessible way. The volume comprises more than 1100 imp. 8vo. pages, and contains, besides the tests made with the 400 tons Emery machine for the service, also records of tests undertaken for private firms. In accordance with United States law, the records of all tests have from time to time to be presented to Congress.

Messrs. Carrick & Brockbank, Manchester, report as follows:—

COPPER.—The stocks have again increased about 5000 tons during the month, the total visible supply on the 1st inst. being 69,371 tons. The increase since the 1st of January is 27,120 tons. The present stock is the largest on record, and it is increasing very rapidly. At the same time the copper trade is in a state of almost complete stagnation, and there is no demand for export. Everybody is asking how long this state of things is to continue. The French syndicate are taking great pains to inform the public of the immense funds at their command, and of their determination to maintain prices. With this object they buy daily the spot copper which comes forward, and in this way the price is kept up. Many millions are thus locked up in the enormous stocks of copper, and the market artificially regulated thereby. Consumers still hold off, and the demand is now the smallest which has been known for years. It remains to be seen how long this state of things can continue.

TIN.—There has been an active demand, and stocks have been considerably reduced. Quotations have fluctuated from £85. 17s. 6d. to £83. 10s. per ton for spot parcels. Three months quoted from 15s. to 20s. per ton higher.

LEAD.—Quotations without alteration.

SPELTER is again lower. Warrants quoted £16 to £16. 5s. per ton, with a downward tendency.

HOME INDUSTRIES.

MANCHESTER, 7th June, 1888.

The Cotton Trade.—The state of business in the yarn trade has somewhat improved since the holidays; an increased number of sales have been made, and there are more inquiries in the market. The extremely low price of silver is, of course, telling against Eastern business, and it remains to be seen whether the offers from that quarter will approach the prices quoted by sellers, or whether the reverse will be the case. At the present time quotations are firm on account of the better tone in the cotton market. The recent advance in spinners' wages has also tended to stiffen prices. All classes of yarns are being firmly held, and there is no desire to yield in any way. Many spinners are still under contract, and therefore are not disposed to sell, except at the full rates. The results of the last quarter's stock-taking show very favourable results. Dividends ranging from 5 per cent. to 12½ per cent. have been declared in many cases, and in others the commencing adverse balances have been very considerably reduced. A question of considerable importance to fine spinners and producers of combed yarns is raised in some correspondence which has passed between the United Cotton Spinners and the Alexandria General Produce Association, with reference to the quality of Egyptian cotton as put into this market. All Egyptian cottons are not so clean as they might be, and the last named Association has rendered valuable aid in improving the marketable article in that respect. The attention of spinners is called to the fact that a new class of cotton, known as Mit-affifi, has been introduced within the last few years, and the cultivation of it is extending. The opinion of spinners on its merits is invited. In the cloth trade a steady business is being done at fairly steady prices. The trade in the Blackburn district is disturbed by the strike of the loomers and drawers, to which we have before alluded. It is not expected that any great inconvenience will be experienced, although it is admitted that if substitutes are not found for those on strike serious results might occur.

A New Development.—In Bolton and the surrounding villages a considerable advance has been made in the manufacture of hosiery. The Rothwell Hosiery Company, Limited, has been in existence three years, and now employs about two hundred hands in the manufacture of a class of goods which have hitherto been principally imported from Germany. The competition in these goods is severe, but it is fairly met by the company, who have been able to find ample employment during their existence. In the cottages in the villages surrounding Bolton there is a large number of machines at work, this being the same system as pursued in Saxony, where cottage labour is extensively employed. Apart from the advantage arising from the employment thus found at home for a number of work-people, there is the satisfaction of knowing that the goods so produced tend to displace others of foreign manufacture.

The Ship Canal.—An extraordinary meeting of shareholders, for the purpose of approving a Bill now before Parliament to authorise certain alterations in the plans of this work, was held on the 4th inst. In the course of the proceedings it was stated that there were 56 steam excavators, 73 locomotives, 2367 waggons, 50 steam cranes, 79 miles of temporary railroad, and 6000 men employed. The excavations during the month of May amounted to 21,371 cubic yards of rock and 1,009,052 yards of soil. The Bill provides for an alteration in the plans which gives 114 acres of water space, against 100 in the old scheme; the quay space being 152 acres, against 83; and the quay frontage 5⅛ miles and 4 miles respectively. There is thus a large increase in the accommodation provided, while the cost is reduced by £23,000. In the course of a few remarks, the contractor, Mr. Walker, said that he had 48,000,000 cubic yards of excavation to carry out, which would mean about 1,000,000 yards per month. This rate was now exceeded, and before the end of the summer he hoped to excavate 2,000,000 yards per month. The Bill was unanimously approved, and the general tone of the meeting was a confident one.

Engineering.—We understand that Messrs. Smith and Coventry, Limited, have purchased the sole right to make and sell in the United Kingdom Knowles' patent key-seating machine which is now being exhibited at the Glasgow Exhibition.

Gosling's Fuel Economisers.—Messrs. E. H. Birley and Co., engineers, Deansgate, Manchester, have been appointed sole agents for Lancashire for Messrs. R. Gosling and Co., of Ipswich, for the sale of their patent economiser.

LONDON, 7th June, 1888.

The Money Market.—The money market continues to be exceedingly easy, the continued flow of gold into this country tending to maintain the rates at a low level. The issue of two new Colonial loans has not had any appreciable effect upon the market, and the owners of capital experience some difficulty in obtaining employment for it at all. The two loans referred to—a New Zealand issue of two millions and the new Land Grant Loan of the Canadian Pacific Railway—are dealt in at considerable premiums; but this hardly represents the actual market estimate of the issues. The public is becoming rather shy about New Zealand borrowing, which has continued for some years on a most extensive scale, especially the commercial situation of the Colony is by no means so bright as might be wished. The dearth of business and the absence of energy on the Stock Exchange are even more pronounced than they generally have been in the height of what is the recognised dull season. Home Government Securities have improved considerably in price, but home railways are still remarkably quiet. The upward move in Great Western stocks, which has been expected for some time by those who have been watching the progress of this line, has now fairly begun. American stocks are still uncertain and spasmodic; but the general outlook in foreign securities has improved, and the stocks of some of the second rate States have gained considerably.

Companies.—The following new companies have been registered since our last report: Guayana Central Railway Company, Ld., with a capital of £800,000; The English Peat Moss Litter Manufacturing Company, Ld., with a capital of £10,000; Argentine Petroleum Coal Company, Ld., with a capital of £500,000; The Gunpowder Company, Ld., with a capital of £200,000; Hewett's Combustion and Steam Generating Company, Ld., with a capital of £150,000; The Foreign Roburite Company, Ld., with a capital of £250,000; John Crowley & Co., Ld., with a capital of £100,000, to acquire the engineering business carried on at the Kelham Iron Works, Sheffield, at Meadow Hall Iron Works, near Sheffield, and at Corporation-street, Manchester; John Tatham & Sons, Ld., with a capital of £100,000, to carry on business as mechanical engineers, cotton brokers and spinners, &c.; The East Acton Brick Works and Estates Company, Ld., with a capital of £50,000; Canada, La Crosse and South Western Railway Construction Company, Ld., with a capital of £200,000; New Balkis Company, Ld., with a capital of £555,000, to work gold and other mines in Africa; Mono Lake Gold Fields of California, Ld., with a capital of £400,000; The Oro Fino Mines, Ld., with a capital of £300,000; The Forssman Transvaal Company, Ld., with a capital of £500,000, to carry on the business of miners and smelters; The Nava Gold Mines Syndicate, Ld. (Spain), with a capital of £20,000; The Malayan (Pahang) Concession Company, Ld., with a capital of £60,000, to acquire mining concessions; The Luxulyan Consols, Ld., with a capital of £60,000, to acquire mining property in Cornwall; The Hermanos Gold Mining Company, Ld. (America), with a capital of £150,000; and The Seringapatam (Mysore) Gold Fields, Ld., with a capital of £200,000.

Metals.—Both tin and copper continue to show the same tendency as reported last week. According to the statistics of copper issued by Messrs. Henry R. Merton and Co., it appeared that the stocks in England and France on the 31st May amounted to 63,887 tons. Including the copper advised from Chili and Australia, the total amounts to 69,487 tons, as compared with 64,349 tons at the end of April this year, and 54,770 tons at the end of May last year.

Hemp.—Although the prospects of the hemp crop in Italy are not very promising, contracts are being made at previous prices. There has not been much business done in Baltic hemp; but owing to the rate of exchange having risen, buyers are now less favourably situated. Manilla hemp has declined in consequence of news having been received of a fall in prices at Manilla.

Railways.—The gross receipts of the twenty-three principal railways in the United Kingdom for the week ending 27th May amounted to £1,314,665 on 15,854½ miles, as compared with £1,272,631 in the corresponding period of 1887, when the mileage was 15,737½ miles. An increase is thus shown in the mileage of 117 miles, or 0·7 per cent., and in the receipts of £42,034, or 3·3 per cent. The second portion of this Whitsuntide holiday receipts is included in this year's returns, whilst the first portion of last Whitsuntide traffic is included in last year's returns.

The Electric Light Installation at the Prudential Assurance Company.—This installation, which we illustrated and described in our issue of the 13th May, 1887, is about to be enlarged. The extension has been entrusted to Messrs. Drake & Gorham, the consulting electricians to the company, and who also designed and erected the installation in the first instance. A third similar engine of 100 h.p. and pair of dynamos are now being put down alongside the existing plant. A new battery, consisting of 264 Drake & Gorham cells, made by Messrs. Elwell-Parker, Limited, of Wolverhampton, is being erected, and will be used mainly in conjunction with the dynamos, thus acting as a regulator in times of heavy lighting.

Honours to Engineers.—Mr. George Barclay Bruce, the President of the Institution of Civil Engineers, has received the honour of knighthood, and Mr. Guildford Lindsay Molesworth, C.I.E., consulting engineer to the Government of India for the Indian State Railways, has been made a Knight Commander of the Order of the Indian Empire.

GLASGOW, 7th June, 1888.

Shipbuilding.—There has of late been a great dearth of orders. Within the last few days, however, inquiry seems to have been a little more active. It is reported that Messrs. Fleming & Ferguson, Paisley, have booked an order for a large screw steamer for the Straits Settlements.

Pig Iron.—On Wednesday, the 23rd ult., pig iron reached the extremely low price of 37s. 1d. per ton. From this point of extreme depression the price has since recovered with fairly rapid strides. The state of the Cleveland iron market, and the tendency to invest on account of the reduced quotations, are doubtless to be credited with having caused the advance. An additional furnace has been blown in. Stocks at Connal's stores are still increasing, and the indications generally do not point towards any substantial improvement. With the extremely low prices still prevailing, the market cannot be otherwise than uncertain.

Mineral Oil.—The combination among the Scotch mineral oil companies is bearing fruit in the declaration of dividends. The Pumpherston Oil Company, which last year had a debit balance of over £8,000, has this year been able to make a profit of £14,235. This suffices to provide for depreciation, &c., and to leave a dividend of 3 per cent. upon the ordinary shares.

Sugar Trade.—Messrs. Connal's report for May shows that prices have been fairly steady during the month. The American Tariff Bill having been set aside, and the disturbance of the American sugar trade by the important changes its adoption would have involved having been for the present avoided, the market seems to have fair prospects of steadiness for the future. The close of the Sugar Bounties Conference also, and its recommendations for the abolition of the bounties, have an important influence in confirming the favourable turn which has been made by the sugar trade during the past few months.

Important Agency Case.—The case of Fossick *v.* Macfarlane, Strang, & Co. has just been decided in the Court of Session by Lord Trayner. The question in dispute was the liability of the defenders for the payment of commission on orders procured through the instrumentality of the pursuer. The agreement between the parties terminated in 1885. It was alleged *inter alia* on behalf of the defenders that the pursuer had during the currency of the agreement acted for another company; but this defence was repelled on the ground of vagueness, and a decision was given against the defenders.

Glasgow Exhibition.—The popularity of the Exhibition still continues, the average daily attendance for the first twenty-four days having been 34,558. There has been some friction between exhibitors in the machinery section and the Executive Council about the placing of signs over exhibits. The Council, it would appear, authorised the removal over night of a number of signs attached to important exhibits, with the result that some of these were for a short time closed to public view by the exhibitors.

Proposed Glasgow Subway.—The promoters of this scheme are not satisfied with its rejection by two successive Parliamentary Committees. They are endeavouring to excite public interest in the question, and public meetings promoted on behalf of the subway scheme are being held in the districts of the city which are affected by the proposal. At a meeting in Hillhead, held last week, a proposal was carried to petition Parliament in favour of the re-committal of the Bill.

(From our own Correspondents.)

LIVERPOOL, 6th June, 1888.

The Shipping Trade of Liverpool in 1887.—From the annual statement of the shipping of the United Kingdom just issued, it appears that the number of ships entered at Liverpool from foreign ports last year was 4477, representing 5,186,393 tons; the number which cleared for sea being 4005, or 4,758,525 tons. Taking the coasting trade, 3408 vessels, or 410,792 tons, were entered at Liverpool, and 3487 vessels of 419,985 tons cleared for ports on the coast. The trade of the four preceding years is shown in the following table for comparison:—

	Vessels entered at Liverpool		Vessels cleared for sea.	
	Vessels.	Tons.	Vessels.	Tons.
1887	4477	5,186,393	4005	4,758,525
1886	4367	5,017,815	4019	4,714,654
1885	4668	5,173,330	4246	4,822,021
1884	4852	5,209,357	4499	4,966,936
1883	5219	5,467,274	4837	4,810,680

Although London stands first in the amount of trade, Liverpool is much ahead in shipowning; Liverpool owning 1488 vessels of 999,286 tons, while London owns 1241 vessels of 362,832 tons. During the last year five sailing ships of 8050 tons, and ten steamers of 2367 tons, were built at Liverpool.

The Cunard Steamer "Etruria."—This vessel on her last passage to New York accomplished the distance from Queenstown to New York in six days one hour forty-seven minutes, corrected time, or nearly three hours less than the previous record.

SHEFFIELD, 6th June, 1888.

Iron and Steel.—Trade prospects in Sheffield are encouraging. Though prices are low, and profits not nearly so large as they were some time ago, the total amount of work sent out is enormous, particularly in Bessemer steel in billet and manufactured into articles. Bessemer rails can now be bought at a very low figure, and the easy prices of all sections are tempting buyers. The chief demand for rails is from distant countries, and these are being sent out in large quantities. Home and Continental companies are still ordering tyres, axles, and railway springs extensively, and couplings are also in greater demand. Perhaps the only branch of Sheffield trade that is in comparative inactivity is the war material department. Armour plates are on very slow order, though it is believed the quietness in the mills is only temporary, and that in the autumn there will be several large orders placed. Firth's and Hadfield's are tolerably busy on projectiles. At Messrs. Vickers & Sons', shipbuilding material

Digitized by Google

is yielding good employment, and Messrs. W. Cooke & Co. are busy on wire roping for pit use, and also for vessels. Picks, shovels, and edge tools are selling readily; and saws, both hand and circular, are in satisfactory request. Sheep shears are demanded by the Colonial markets; and best descriptions of cutlery find a brisk sale in London, Paris, and other cities. There is an unsatisfactory stagnation in manufactured iron, so far as the Sheffield demand is concerned. Angles can be bought at £5, bars £4. 17s. 6d., hoops £5, rods £5 to £5. 10s., sheets £6, and plates £6. 15s.; and there is comparatively little business being done even at these reduced rates.

NORTH STAFFORDSHIRE, 6th June, 1888.

The Pottery Trade. — The improved demand still continues in the china and earthenware branches of the pottery industry, although the selling prices do not show any alteration in the right direction. For the week ending May 19th—the last for which returns have been issued—there were 2277 packages shipped from Liverpool to the United States, as compared with 1168 in the corresponding week of last year. From January 1st to May 19th there were 38,185 packages, being an increase of 5173 as compared with the same period of 1887. At some future period the Americans will doubtless be in a much better position than at present to satisfy their own requirements in this direction, and it behoves manufacturers to look to the development of other markets rather than to lean entirely on the demand from the United States. At the present time, some good sales are being effected for the Colonies; but the Continental demand is limited, and the home trade continues dull. On the whole, however, there is a better feeling as to the future amongst local manufacturers.

Staffordshire Potteries Water Works Company.—The annual meeting of this company was held at Hanley last week, when a dividend at the rate of 6 per cent. free of income tax was declared. The chairman stated that in spite of the abnormally dry season of last year the whole district had been supplied as usual, while the rentals had increased, and extensive renewals had been made at the Wallgrange station. The company were congratulated on the recent successful application to Parliament for powers to increase their works, and the question of site for the new buildings necessary is now under consideration, attention being centred on one at Hatton and one at Cresswell.

BIRMINGHAM, 6th June, 1888.

The Iron Trade.—In the iron trade of this district the prospect is rather more favourable, and an increase in the output of iron has taken place during the past few weeks. Two furnaces have been blown in, and in consequence the make of pig iron has increased by some 400 tons per week; up to the present time, however, the increase has not resulted in any accumulation of stocks. There is a tendency towards the production of a lower quality of iron, the high class makes of Staffordshire having for some years been supplanted by cheaper makes from other districts. Foundry iron of high quality brings from £2. 17s. 6d. to £3. 15s., and lower grades from £1. 10s. to £2. 12s. 6d. The Old Factory Iron Works and the Hope Iron Works—two concerns which have been standing idle for ten years—have been re-started, and are now turning out manufactured iron. For the latter class of goods a fair demand is manifested; marked bars bring £7, and unmarked iron sells at about £5. A good trade is being done in sheets at £6 to £6. 5s. The steel trade continues to be good.

The Hardware Trade.—A fair demand exists for heavy castings for engineering purposes, and large quantities of this class of goods are being sent abroad. The recent revelations concerning the state of the War Department are tending to stir business. The lighter class of hardwares, such as small safes and bedsteads, are in a satisfactory condition; but the same can hardly be said of goods which are mostly bought for winter requirements. Electrical engineering concerns find no lack of orders, and some good orders have been taken for dynamos by local firms. A large meeting of manufacturers and others interested in the gun trade has been held in the Birmingham Town Hall to protest against the action of the Government in the matter of the Small Heath factory. Some hopes are entertained that the end of the copper ring is within measurable distance.

DERBY, 6th June, 1888.

Electric Lighting.—The lead of Messrs. Bardill and Co., who have now for some considerable time lighted their shop in Peter-street by electricity, is about to be followed on a much larger scale by Messrs. John Davis and Son, who contemplate putting down in their premises at All Saints' works, a large electric plant for the purpose of distributing light and power to neighbouring shops.

Claye's Waggon Works.—Considerable damage was done to this establishment at Long Eaton by a fire which broke out in the engine room at the iron works. The engine and a number of the lathes have been damaged, and many men have consequently been temporarily thrown out of work.

Bridge Work.—The Phœnix Foundry Company have been sending out some very large castings to complete their contract for the iron work of the Battersea Bridge. Messrs. Andrew Handyside & Cd. have secured the order for the Grange Town Bridge, Cardiff, the iron work for which is to cost £23,000.

LEICESTER, 6th June, 1888.

Wool Spinning and Yarn Trades.—There has been a slight increase in the trade transacted in the wool market during the past week, but the aggregate turnover is very limited. The uncertainty in prices continues, and there is not any likelihood of rates becoming at all fixed until after the local wool fair this month, when the new clip will be offered. Growers and country dealers are not pressing sales, and their rates are a fraction lower. Staplers are not operating at present, and for the next week or so they will remain inactive. The prevalent impression is that the prices of the new clips will hardly hold up to the present rates, unless there should be a considerable foreign demand. Very little new English wool has been offered, but some Irish has been sold at ½d. decline on late rates. Spinners are not doing a very heavy trade, and their orders are principally small ones, as the unsettled state of the market makes the undertaking of large contracts risky. Worsteds are in moderate demand; the best business is being done in cashmeres and fine yarns, and for these classes better prices are obtained, on account of stocks being low.

Hosiery Trade.—A healthier tone pervades this industry, and most departments of it are better employed. There is an improvement in fancy goods and specialties, and the tendency of prices is to harden. Some good contract orders have been booked, which will find employment for the machinery for some months to come. As orders for fancy goods are now coming to hand freely, business will be improved during the next month or two.

BARROW-IN-FURNESS, 6th June, 1888.

New Industries.—Much progress is being made in the construction of the extensive storage accommodation at Ramsden Dock, Barrow, for the import petroleum trade, and an early cargo of the oil in bulk is expected.—Although the prospectus of the new wood pulp company at Barrow has not yet been issued, arrangements are proceeding for the building of the works at the east end of the Cavendish Dock. Most of the capital required by this company has already been raised.—Although not much has been said lately about the Anglo-American Food Supply Company which is being developed in connection with the port of Barrow, the preliminaries which are incidental to so great an undertaking are proceeding satisfactorily, and next year will probably witness the inauguration of this very large and important trade to Barrow. Several subsidiary industries, such as soap and tallow works, tanneries, &c., are contemplated in connection with this new company.—It is rumoured that a new company is to be formed to take over the Vulcan Steel and Forge Company's works in a new trade. Some American capitalists have viewed the works, and in all probability one of the features of the industry to be centred at this place will be the construction of steel railway trucks on the bogie principle, for employment on the British railways. With all these schemes in the air, the future of Barrow seems to be well assured.

Iron and Steel.—There is a rather better tone in the iron and steel trades, and the inquiry is much more active, particularly for Bessemer samples; mixed numbers of the latter are quoted at 42s., and No. 3 forge at 41s. per ton net f.o.b. Steel rails are fairly brisk, with heavy sections at £3. 16s. 6d. and light sections at from £4 to £4. 7s. per ton. Ship plates are not so busy, but are still quoted at £6. 5s. per ton, and angles at £5. 17s. Iron ore is quiet, at from 8s. to 10s. 6d. per ton net at the mines.

MIDDLESBROUGH, 6th June, 1888.

Pig Iron.—The turning point seems to have arrived at last. Prices have not actually risen, but the tone is firmer and the tendency is undoubtedly in the direction of a rise. This has come about, however, more by the improved tone of the Scotch market than by the favourable influences at work in this district. The average quotation is still 31s. 1½d. for No. 3 G.M.B., the same as last week; but there is more activity and greater disposition to do business.

The Iron Masters' Returns.—These returns for the month of May are highly favourable, and are full of encouragement for the future. They show that the make of pig iron is much about the same, the slight increase of 4118 tons over that of April being more than counterbalanced by there being one working day more in May. The shipments form the great feature in those returns, having amounted to 107,826 tons, as against 90,641 tons in April, and 74,517 tons in May, 1887. The shipments for last month are the highest on record, the nearest being those of September, 1879, when they amounted to 101,154 tons. The 107,826 tons include 8326 tons of pig iron other than Cleveland. During the month 120,378 tons of Cleveland pig were made; in shipments there were disposed of 99,500 tons, and in local consumption and delivery by rail 58,609 tons, amounting in all to 158,109 tons. Thus a decrease was made on stocks to the extent of 37,731 tons. The total stocks are thus reduced from 586,492 tons at the end of April to 548,761 tons at the end of May. The average market price of No. 3 G.M.B. in May was 31s. 2d., as compared with 31s. 9d. in the previous month.

Manufactured Iron and Steel.—The returns of the accountant for the Board of Arbitration for the two months ending April 30th show that over the whole weight invoiced of rails, plates, bars, and angles, there has been an average advance of 5d. in the ton, as compared with the same months last year. The re-starting of the Newport Rolling Mills has been taken as a sign of revival. There are now no mills of importance in this district standing, the Ayersome Works having maintained the start made a short time ago.

Salt.—This industry is thriving, and extending its operations. During the past seven months 16,600 tons have been exported to both home and foreign ports. Dundee, Perth, and Peterhead are amongst the former; and Frankfort, Dantzic, Memel, Christiania, and Copenhagen amongst the latter. The stocks of salt are depleted, on account of the demand being greater than the supply.

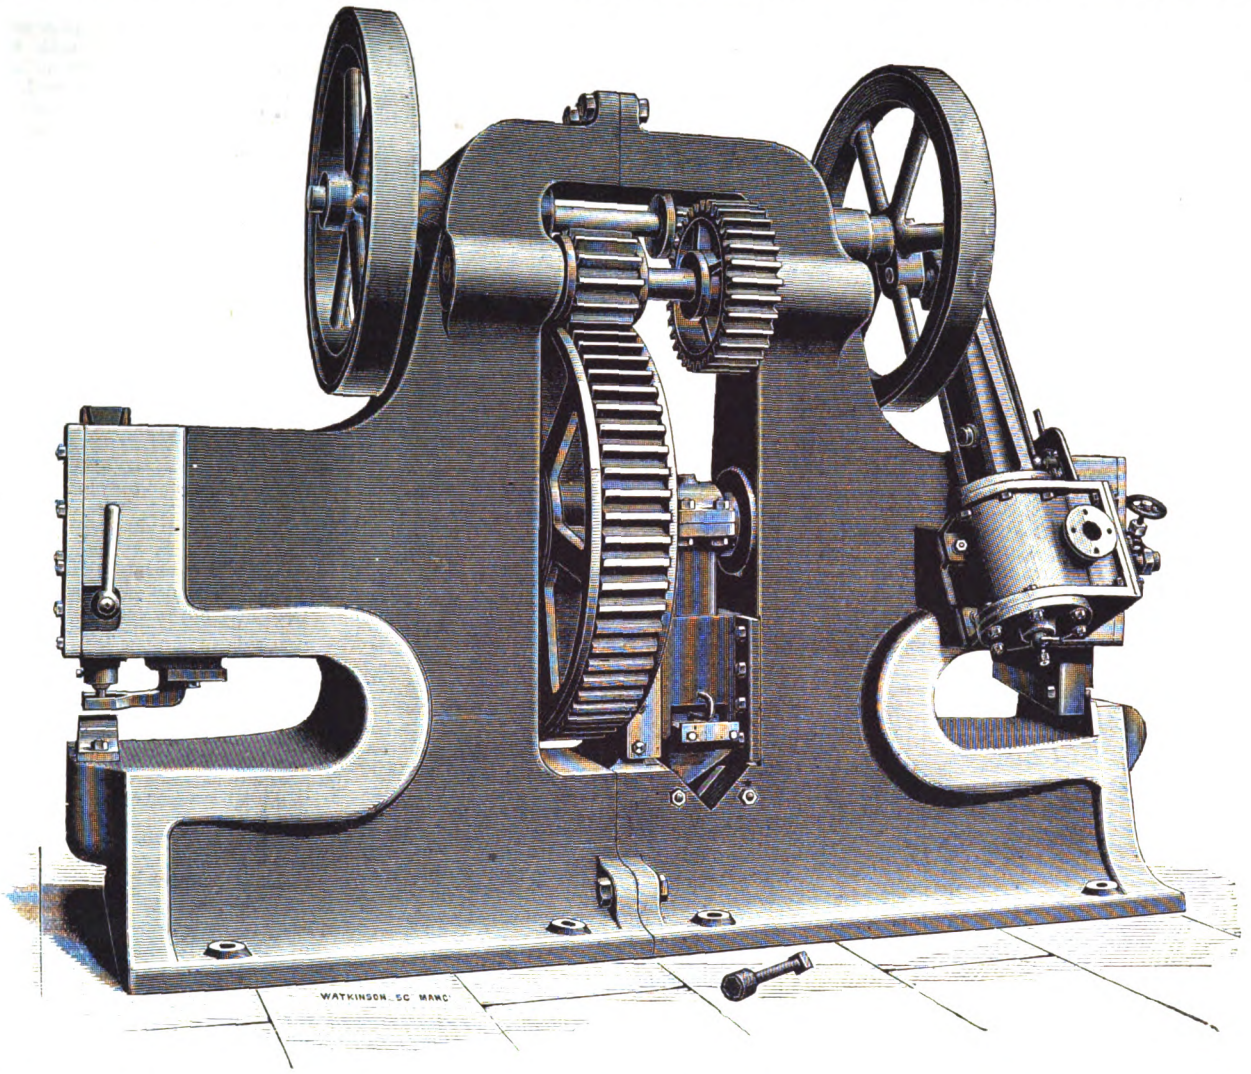
NEWCASTLE, 6th June, 1888.

Trade Disputes.—Owing to the prevalence of trade disputes business in the leading industries of the district is in a most unsettled state. The fitters in several of the Mid-Tyne engineering shops have come out on strike for an advance in wages of 2s. per week, the present rate being 31s. per week; and the operatives in the remaining factories within the district named threaten to cease work a week hence, unless the advance is in the meantime conceded. The employers show a strong determination to resist the claim, the contracts now on hand having been taken at prices which preclude the possibility of allowing an increase in the cost of production to any material extent. In the shipbuilding trade wages questions are also causing much interest. The ship joiners have been on strike for more than a week; but as yet their absence from work does not seem to have caused much inconvenience to builders, as the most pressing work is being executed by the apprentices, who are, of course, more closely supervised than hitherto by the foremen. The platers' helpers have returned to work, having failed in their attempt to get the wages rate advanced; but the platers and other operatives engaged in the iron and steel work have now put in a claim to have their wages advanced 10 per cent. on 1st July, and thus a new trouble is provided for the employers to deal with. The occurrence of these wages troubles at this moment is particularly inopportune, as trade is only just recovering from a long depression, and it is to be feared that these unhappy differences between employers and employed will, for a time at all events, check any further progress towards prosperity.

Ordnance Works.—A large order for guns of 10-inch bore, as well as for carriages and other appliances, has just been secured for the Elswick Works of Sir W. G. Armstrong, Mitchell, & Co., and already a very marked increase of activity is to be noted in the various departments. For some months past discharges of men have been taking place weekly; but this state of things has been recently changed, and constant additions are being made to the number of hands employed throughout the establishment. In some shops where night work was discontinued a few months ago, arrangements are to be made for returning to the system of running the machinery night and day.

India-rubber Goods.—The demand from India for india-rubber goods required for engineering purposes is showing considerable improvement, and this week Messrs. Geo. Angus & Co., Limited, are sending a large consignment to Bombay.

The Coal Trade.—The coal shipments from Tyne Dock for the week ending June 2nd show an increase of several thousand tons over the shipments for the corresponding week of 1887. The steam coal collieries are just now working regularly, but the collieries where other qualities are produced are in most cases only working intermittently.



DUNDEE, 6th June, 1888.

Flax and Jute Trades.—The linen and jute trades in this district have been fairly active during the past fortnight. In flax, only a small spot business is being done, as spinners have full supplies to satisfy their present wants. On contract the tone is firm. The rise in exchange has caused the sellers to hold for an advance, and this to some extent checks business. Flax and tow yarns meet with a slow sale, and the business offering is only sufficient to take off the present production. Foreign wet spun yarns are offering freely in this market at low rates. There is only a moderate demand for linen; but makers of fine goods are still well employed. Sailcloth is in better request, but prices are not considered satisfactory. In jute there is an increased inquiry for the old crop, and the prices are maintained. A considerable business has been transacted in the new crop at firm prices. Calcutta telegrams report a strong market, and that balers are not disposed to make further contracts. The market for jute yarns is fairly active, and as spinners are well employed, prices are firm. In jute fabrics, most widths of Hessians are in request, and there is an upward tendency in prices. Sacking, bagging, and tarpaulin are in steady demand, without any material change in quotations.

The New Tay Bridge.—In a lecture on "Earthquakes, and How to Measure Them," delivered at the Royal Institution last week, Mr. J. A. Ewing, professor of engineering in University College, Dundee, gave the results of seismographic observations taken on the new Tay Bridge. The seismograph recorded motions during the whole time a train was on the bridge, and was placed on the southernmost of the great girders, where it was expected that the vibration would be greatest. Whenever a train went on the bridge at the Dundee end, a distance of 1¼ mile, oscillations were observable, and they gradually increased from $\frac{1}{100}$in. to a maximum of $\frac{1}{8}$in.

PUNCHING AND SHEARING MACHINE.

PUNCHING AND SHEARING MACHINE.

We herewith illustrate a punching, shearing, and angle iron cutting machine, constructed by Messrs. George Booth & Co., engineers and machine tool makers, Central Iron Works, Halifax. The machine is of the ordinary eccentric type, and specially adapted for punching steel plates. The eccentric shaft is made of Bessemer steel, and is driven by powerful double gearing. The machine is actuated by a steam engine affixed to the framing, having a cylinder 8in. diam. One end of the machine is capable of punching holes 1¼in. diam. through plates 1¼in. thick 24in. distant from the edge of the plate, while the other end of the machine is constructed to shear plates 1¼in. thick 24in. from the edge of the plate. In the centre of the machine an arrangement is provided for cutting angle irons up to 6in. by 6in. The slides are fitted with large wrought iron case hardened dies, and the slides for the punching and angle iron cutting arrangement are provided with a stop motion for disconnecting them when not in use. Messrs. Booth are now engaged in constructing special machine tools for modern boiler works, which we hope to illustrate in a future issue.

THE IRISH EXHIBITION.

On Monday last, another exhibition was opened in London, which is suffering just now from a plethora of such enterprises. It might have been supposed that the Italian Exhibition at West Brompton, and the Anglo-Danish Exhibition at South Kensington, would have been sufficient for one season; but, in addition to these, we now have an Irish Exhibition at Olympia. The last named will probably be successful in bringing about the result desired by the promoters, viz., to place before the English public a clear view of the predominant industries of Ireland, and to awaken public interest in the efforts being made to revive her trade. It is almost unnecessary to mention that the Exhibition when opened was far from complete, as this is so generally the case that in the event of everything being in readiness at the time of inauguration, as was the case in Glasgow this year, and at Manchester last year, the fact is so exceptional that it creates surprise. Notwithstanding this condition of unreadiness, which is, however, more conspicuous in the grounds than in the business sections, sufficient is seen to demonstrate the interesting nature of the Exhibition from an industrial point of view. Many Irish industries are very well illustrated, and linen, lace, embroidery, and cloth are well to the front, to say nothing of Irish whisky, which is to be found in all parts of the building. Soap, candles, porcelain, printing, chromo-lithography, engineering, and shipbuilding are also represented; but it is to be regretted that no attempt has been made to effect any classification.

Mr. William Spence, of Dublin, has on view a 20in. gauge locomotive of Geoghegan's patent to work at 180lb. pressure, such as are used for indoor work at Guinness's Brewery. It has a wheel base of 3ft., and is capable of drawing a rolling load of 40 tons. Attached to it are a truck for carrying barrels and a tip waggon for malt, &c. The locomotive was exhibited last year at Manchester. Mr. J. C. Wallace, of Belfast, is erecting one of his flax scutching machines, and Messrs. Kennedy & Son, of Coleraine, are present with an "Empress" turbine. Some excellent work in wrought iron gates is shown by Mr. B. Watson, of Cork. The shipbuilding interest is represented by Messrs. Workman, Clark, & Co., of Belfast, whose exhibit consists of models of steamers and sailing vessels built by them.

At the stand of Acheson Harden, Limited, a good example is given of Irish domestic industries, hand loom weaving being in progress here, and the printing of the patterns is also done by hand. The importance of these manufactures may be gathered from the fact that this firm alone employs at its mills, and at their homes, over seven thousand hands. Close to this firm's exhibits are found Irish homespuns, made by Messrs. Boyd & Co., of Belfast; hand made socks and shirts, by Messrs. McHugh, of Belfast; and fine specimens of embroidery, by the Irish Linen Company, of Belfast, some of which are exceedingly valuable, £72 per dozen being asked for some embroidered handkerchiefs. A large display of Kerry homespuns and tweeds is made by Mr. J. Revington, of Tralee. At the stand of the Belfast Ropework Company, Limited, various kinds of cordage and rope are shown.

The Exhibition, which has the support of a number of influential gentlemen, is to remain open for five months.

IMPROVED CASING FOR LOCKS.

In former years, before the jerry builder had begun his operations, the doors of dwelling houses were made of sufficient thickness to take a mortise lock without being seriously weakened by the recess which had to be cut out to receive the body of the lock. Now, however, the low prices at which buildings are erected compel the builder to exercise economy in every direction, and especially where scantiness of material is not immediately apparent. Thus the doors are made of wood too thin to take a

mortise lock safely, and rim locks, which project on the face of the door, have to be adopted. These, however, are unsightly, and with a view to obtain the appearance of a mortise lock, and yet avoid the weakening of thin doors, Mr. Lewis W. Goold, of Birmingham, is now introducing a lock, which we illustrate herewith. In this lock the outer casing plate is extended up and down the stile of the door, thus forming a strengthening piece to make up for the wood cut away to receive the body of the lock. The material left on the outside is double as thick as would be the case were the lock mortised into the door in the usual way, with material left on either side. This extra thickness allows of the furniture being more substantially fixed. The casing plate also forms a finger plate, and obviates the necessity of cutting away a part of the door, as required for the bolt box of an ordinary rim lock.

Advertisements intended for insertion in the current week's issue must reach the Manchester Offices not later than first mail delivery on Thursday morning. Scale of charges for displayed advertisements on cover and inside pages will be forwarded on application. Orders for single advertisements must be accompanied by payment in order to insure insertion, the charge for which is 2s. 6d. for the first four lines or under, and 8d. for each additional line; one inch and over at 7s. per inch; the line averages eight words. While all practical regularity in the insertion of serial advertisements will be observed, it can only be absolutely guaranteed in the case of those ordered to appear weekly.

All accounts are payable to the Publisher, JAMES F. BUTTERWORTH, *70, Market-Street, Manchester. Cheques should be crossed Manchester and Liverpool District Bank, King-street Branch, Manchester. Post Office Orders to be made payable at Manchester.*

FRIDAY, 8TH JUNE, 1888.

OUR NAVAL DEFENCE.

THE subject of our national defences has recently been discussed in articles in newspapers and journals and at public meetings of various kinds, and judging from the general expression of opinion, it is evident that some definite plans for naval organisation, more in keeping with the requirements of the times than those at present existing, will be forced upon the Government. It is quite impossible for us to notice all that has been said upon the subject; but two meetings of special importance have recently been held, at which the speeches delivered are worthy of serious consideration, embodying as they do the opinions of men of wide experience and of all shades of politics. The first was the occasion of a lecture by Admiral Colomb, at the United Service Institution, on "The Naval Defences of the United Kingdom," and the second, of an address by Admiral Hornby, on the "Defence of Merchant Ships in Case of War," before the London Chamber of Commerce; and the subjects of these two addresses mark the distinction which should always be made in considering our naval strength—viz., the questions of the battle ships and the defence of the mercantile marine. The latter is the one which most directly affects the industries of the country, and therefore we will state shortly some of the views expressed by Admiral Hornby and those who took part in the discussion. The Admiral commenced by premising two things—first, that his subject being so large he could not describe it in detail; and second, that owing to the want of experience in steam warfare at sea he could quote no authority in support of his opinions. It was evident that the points of danger during war, to merchant ships, were those where they drew together, such as near straits and projecting capes. Their safety was in the vicinity of neutral Powers or of points occupied by friendly squadrons. Foremost among the former for us was the space between Cape Clear, Ushant, and the Land's End, because it covered the entrance to the English and Irish Channels. The next deep sea portion to be guarded was Cape Finisterre, and, going still further south, Cape St. Vincent—the turning point of the Mediterranean. After examining the various conditions affecting each of those stations, the Admiral said if he were to form a very moderate estimate—and looking at the number which our ancestors thought to be right in 1794, viz., five frigates—he thought fifteen cruisers at the Channel mouth would be very moderate, seeing that the gross tonnage of British vessels was now probably seven times as great as it was then. He would ask for one as a relief for one of the fifteen cruisers which might be reckoned on to be always coaling. At Cape Finisterre he would ask for four, and at Cape St. Vincent for three. Allowing for the proportion of additional vessels required to keep those effective, six and four would be required for these stations respectively, or ten in all. The number off Cape Verd Island must depend on that of the vessels stationed at Goree; but if he said arbitrarily that he should want four there and three on the line, he would have to detail in all eight for Goree, and say four for the line, or a total for the five squadrons of thirty-eight. Now, judging from the Navy Estimates, the number of effective ships — viz., ships that were supposed to make sixteen or more knots at sea—they proposed to keep was very small, for the number promised them by 1890 was forty-two, and many points of the globe required to be occupied. He said it might be objected that he did not propose to make any use of our corvettes, or of the armed merchant ships. As to the corvettes, with perhaps three exceptions, none were designed to go more than thirteen knots on the measured mile, and practically they could maintain a speed of eleven knots at sea. To send them to cruise against vessels that could go sixteen knots was, to his mind, as useless as to send a coach and four to catch the Great Northern express. As to the armed cruisers, they were not built to fight, while the duty of these squadrons would be to fight. He valued the armed cruisers too highly to misuse them. They were built for speed and to carry information, and at present their number seemed lamentably small. In 1794 we possessed 185 cruisers, irrespective of bombs and fireships; and if we multiplied that number by three, as he had done in proposing cruisers for the Channel mouth, we should have 555, and taking into account the vast area to be defended, he had no reason to suppose that that number would be in any way in excess, as he was of opinion that our organisation for protecting the mercantile marine during a European war would have to number its cruisers by hundreds if it would protect all the routes that were largely frequented by our ships.

The Earl of Carnarvon moved a resolution thanking Admiral Hornby for his address, and expressing the opinion that co-operation between Her Majesty's Navy and merchant shipowners would appear to offer a good basis for the immediate organisation of such a reliable scheme of defence as would inspire commercial confidence, and insure the maintenance of our food supply in the event of war between the United Kingdom and any foreign Powers. He gathered from the paper two considerations—first, the altered condition of naval warfare; and second, the total inadequacy of our present navy. He ventured to say that it was a widespread belief at the present moment in the nation that in the event of a European war there would be great danger for us abroad, and there would not be security for us at home. He condemned the present system of departmental management, and he said that support of his opinion was to be found in the endless reports which had been made from time to time condemning it, while the miscarriages which had taken place had shocked the public mind. He did not wish to advocate public extravagances. He thought that our expenditure was sometimes a great deal more than was necessary, just as our saving was frequently unwise. What he did say was that we had no continuous and well ordered policy in these matters. Such was not the case in foreign countries. France, with all her changes, did not change in her naval and military policy. Italy adhered to the lines she laid down. Germany accepted and admitted of no variation. We alone, who were more vulnerable than any of the other nations, drifted on, idly dreaming. He trusted, however, that before long the country would become alive to the importance of this question, and give its answer in clear and emphatic language. Lord Brassey seconded the motion, and said, while he sympathised with the Government in their desire to spare the taxpayers unnecessary burdens, he was not sure it would not

Digitized by Google

lead to true economy, if it were the manifest determination of the nation not to be beaten in their state of preparation for the purposes of naval defence. He believed that if it were to go forth that for every cruiser which might be laid down by a rival Power we were prepared to lay down three, it would have a very valuable effect in reducing naval expenditure all round. Although this opinion was well received by the members of the Chamber of Commerce, we think it might turn out a dangerous and extravagant game, and trust that something more moderate will be proposed. We agree with the hope, however, which was expressed by several speakers, that the Government will endeavour to meet the shipowners, and by a liberal and judicious expenditure obtain the aid of their vessels; and, further, that more attention will be paid to the development of the Royal Naval Reserve.

Admiral Colomb's paper was scarcely of the same general interest as Admiral Hornby's, as he treated the subject almost entirely from the naval tactician's point of view, and argued for the advisability of making the fleet effective, rather than of spending money on land forts. He reviewed past naval history, and explained the policies followed by Lords St. Vincent and Howe. The former consisted essentially in blockading the enemy in his own ports, the latter in having squadrons stationed at the most vulnerable points, leaving the enemy free to take to the sea if he felt strong enough to encounter our fleet. With our immense mercantile fleet this would give the enemy a great advantage over us, and it is probable that the altered conditions of modern warfare and the developments of commerce would require a combination of the two systems; for as the First Lord of the Admiralty lately said, nothing but actual experience could justify any confident prediction as to how a thoroughly efficient protection can be given by any fleet to a commerce whose sea-going steam tonnage is double that of the rest of the world. This may seem a somewhat pitiful conclusion to come to, but it by no means indicates any inclination to stand still while our neighbours are advancing. Our land forts should receive some attention, and it is so far satisfactory to find Admiral Elliot declaring that the defences raised at our great depôts and in the Thames were such that no enemy would dare to attack them. We should, moreover, pay all attention to the developments of torpedo warfare. We should see that we have a sufficient number of fast cruisers to protect our commerce, although in many cases merchant ships might carry sufficient armament to protect themselves, at least against privateers. With regard to line-of-battle ships, it would be found both difficult and dangerous to blockade an enemy's harbours, as we have now to face the operation of torpedoes. Perhaps, as Sir George Elliot maintained, the best way of ending a war was by letting the enemy get to sea, and there giving him a thrashing.

YARROW'S "ZEPHYR" LAUNCHES.

One of the most interesting papers read at the last meeting of the Institution of Naval Architects was by Mr. A. F. Yarrow, on the possible advantage of using highly volatile liquids in lieu of water for the purposes of propulsion. This paper, of which we published an abstract at the time (see *Industries*, Vol. IV., page 339), elicited very little discussion, and it seemed almost as if the members of the Institute had failed to appreciate the great importance which any improvement in heat engines must necessarily have, not only for the propulsion of launches, but also for general work. Meanwhile, Messrs. Yarrow have continued to develop the new type of engine, and have brought it to a state of perfection which leaves no doubt that the advantages which Mr. Yarrow in his paper described as possible, have in actual practice been fully realised. The system is not new, as we learn that more than thirty years ago a French inventor suggested the use of highly volatile liquids instead of water for working engines; and if the records of the Patent Office were searched, it is very likely that the same idea will be found to form the subject matter of various patents. In its present form, or rather in the form which it had before Messrs. Yarrow introduced the improvements to be presently described, the engine is the invention of a Swede, and was first built in America. To that country also belongs the credit of having recently perfected the use of ammonia as a working fluid for engines (see *Industries*, Vol. IV., page 530); and we learn from Professor Forbes, who, whilst in America, has carried out some tests with this engine, that the saving in fuel when the engine is worked with ammonia is about 50 per cent., as compared with the amount of fuel used when the same engine is worked by steam. Theoretically speaking, the efficiency of a heat engine, and therefore the amount of power obtainable with a given expenditure of fuel, should, of course, depend only on the range of temperature, and should be independent of the working agent. Whether this be water, hydrocarbon, ammonia, or any other substance, the efficiency should for the same range of temperature be the same in all cases. But in practice this is not found to be the case, or rather there are modifying circumstances which are not taken into account in the theoretical formula for the efficiency, and which tell largely in favour of the liquid having a lower boiling point than water. It is not our present purpose, however, to deal with the theoretical part of this question. Our business is to describe the improvements recently introduced by Messrs. Yarrow in the hydrocarbon engine.

Messrs. Yarrow have set about their work in a very methodical and scientific way. At their works in Poplar they have an experimental room, in which there are three small engines, each with its boiler, which were used in this investigation. The smallest of these engines is a mere model, and Messrs. Yarrow soon found that no reliable quantitative results could be obtained with it. The next larger engine was used when testing the effect of a mixture of water and gasolene as a working agent. These results were also unsatisfactory, partly because of the small size of the apparatus used, but chiefly on account of the practical difficulties experienced with the boiler. Gasolene is exceedingly volatile and inflammable, and will find its way through pores in metal or through joints which, to all appearances, are perfectly steam and water tight. It is evident that when gasolene is contained, so to speak, in bulk inside the boiler, absolute tightness of the boiler fittings is of much greater importance than where the boiler is used with water alone, not only because of the loss of gasolene, but also on account of the danger of any escaping gasolene catching fire. It was also found difficult in the small engine to keep the glands sufficiently tight to prevent the escape of gasolene vapour without putting undue friction on the engine, which would, of course, vitiate the brake experiment. The trials with the largest engine of the series were, however, perfectly satisfactory, and we will briefly describe the arrangements. At one end of a table of convenient height, there stands a small vertical boiler with Field tubes fired by gas from a Fletcher burner. The quantity of gas was measured during each experiment, which lasted for about three hours. By the side of the boiler, and occupying the rest of the table, is a screen, against the back of which is fixed vertically the experimental engine; whilst various valves, tanks, and other apparatus used in the measurements, are fastened to the sides of the screen and at the top of the table. The boiler is filled with water to the usual working level, and within the steam space there is a copper coil, through which the gasolene is passed in order to be vaporised. A duplicate set of pipe connections is provided, so that the engine may be worked either by steam in the usual way or by gasolene vapour, in which case the steam pipe is closed, and the steam generated in the boiler merely serves to heat the coil by transmitting the heat from the burner to the gasolene, the steam continuously rising to come into contact with the coil, where it is condensed, and falls back into the boiler to be re-evaporated. The experiments were made at 50lb. steam pressure, which was kept constant both when steam was used direct as the working agent, and when hydrocarbon vapour was used in the engine; consequently, the initial temperature at which the working agent was supplied to the engine was approximately the same in both cases. The final temperature was, however, lower when the hydrocarbon was used, since its boiling point at atmospheric pressure is only about 180°F. We should, therefore, expect in this case a small gain in efficiency; but the gain practically observed is much greater than corresponds to the difference in range of temperature. Without going into exact figures, we may mention that, with the hydrocarbon vapour, the power developed on the brake was about twice that which could be obtained with steam for the same quantity of gas burned under the boiler. Thus there appears to be an absolute advantage in working steam engines not with vapour of water, but with that of some highly volatile fluid, and in the "Zephyr" launches this fact has been utilised.

In the first launch described by Mr. Yarrow in his paper, the fuel and the working fluid were the same, both being supplied from the same tank; but as the storage of large quantities of gasolene is not unattended with certain risks, and as this liquid cannot be readily obtained in all localities, Messrs. Yarrow have altered the original design in such a way that the light hydrocarbon is only used as the working agent, and any common petroleum of commerce is used as fuel. This can be obtained in any locality with almost greater facility than coal, and consequently the improvement is of great importance for pleasure yachts, which may often find themselves long distances away from home. A further advantage is the lower cost of the common petroleum. As in the older engines, the boiler in the latest form consists of a coil of copper pipe, below which is a burner. To start the engine a small petroleum lamp is lighted, which heats the petroleum and gasifies it before it issues from the burner; but after the engine is started the lamp may be extinguished, as this heat is supplied by the burner itself, somewhat on the same principle as in the lamps used by costermongers. The petroleum is carried in a small tank, distinct from the tank containing the gasolene, and by means of a small hand pump an air pressure of about 5lb. is first raised above the petroleum to force it to the burner. The hand pump must be worked from time to time to keep the pressure up, and with it the flow of oil. A valve in the pipe which carries the petroleum to the burner regulates the size of the flame and consequently the heat supplied to the boiler, which is evidently the only correct principle for regulating the power developed by the engine. The gasolene vapour generated in the coil of the boiler passes through the engine doing work, and is again condensed in a tube laid outside the boat close to the keel, this portion of the apparatus being the same as already described in Mr. Yarrow's paper.

The tank containing the gasolene is placed preferably in the bow of the boat, and divided from the central portion by a water tight bulkhead. Forward of this bulkhead there is a space open to the water, so that even in case of collision, when the tank might be broken, the gasolene will not find its way into the boat itself, but will flow out direct into the sea. The gasolene tank need not be opened except to replenish it so as to make up for the small amount of leakage which might have taken place through the glands of the engine; but to judge from the almost complete absence of smell, even close to the engine, this leakage seems to be very trifling. By the courtesy of Messrs. Yarrow's manager we had recently an opportunity of making a run in one of these "Zephyr" launches. As compared with an ordinary steam launch the passengers enjoyed very much more comfort. The machinery only occupies a small portion of the boat at the stern, and the whole of the central portion is available for passenger accommodation. There are no smuts, no smoke, no blowing off of steam, and there need be no noise, although in the boat in which we travelled the reversing gear of the engine was certainly somewhat noisy. This, however, is not the fault of the system, but merely of the particular engine employed. The system is evidently applicable to any type of launch engine. The most striking feature of the machinery is its light weight. The weight of the whole of the propelling machinery, consisting of boiler, engine, and the various pumps, amounts to only 3cwt., and the total weight of the boat in working order is 1 ton, whereas a steam launch of equal capacity would weigh about 2 tons. The engine is a triple single acting engine, with 3¼in. cylinders and 4in. stroke, and when running at 280 revolutions per minute it develops 4 h.p. It is certainly a great achievement in modern engineering to produce an engine and boiler weighing less than 1cwt. per actual horse power developed, and even if we include the weight of the oil tanks and oil, the total dead weight of machinery is far less than that of engine, boiler, and coal on a steam launch of equal size.

The cleanliness of a "Zephyr" launch may be inferred from the fact that a white handkerchief held over the funnel is not in any way blackened by the products of combustion. A further advantage of these launches is the short time in which they can be started. When everything is cold, the time occupied from the moment that the order is given to start until the boat is under way is only about five minutes; and when the machinery is warm, but the fire extinguished, the time scarcely exceeds one minute. To regulate the speed it is only necessary to adjust the size of the flame of the main burner. As regards the consumption of fuel, no very accurate data have as yet been obtained; but, roughly estimated, it varies in the launch we inspected from one to one and a half gallons per hour, the speed being eight miles per hour. Taking the specific gravity of common petroleum as ·82, we should thus have an average consumption of 2½lb. of petroleum per horse power hour, which, at 7d. per gallon, is less than 2¼d. per horse power hour. Although this figure is not quite so low as is claimed for gas engines, it is by no means prohibitive in cases where only small powers are required for work on land; and we think it highly probable that these "Zephyr" engines will find considerable application in such cases where hitherto explosive engines working with gas or petroleum have been employed.

MINES (LIMITATION OF HOURS) BILL.

A Bill bearing this title has been introduced into the House of Commons with the object, according to the preamble, of limiting the hours of work underground of persons employed in mines. It is backed by Messrs. Cunningham-Graham, Abraham, Pickard, Conybeare, and Cremer, and is a short Bill consisting only of three clauses. It enacts that a person shall not in any one day of twenty-four hours be employed underground in any mine for a period exceeding eight hours, from the time of his leaving the surface of the ground to the time of his ascent thereto, except in case of accident or other emergency, and that any employer, or the agent of any employer, employing or permitting to be employed any person in contravention of this enactment, shall be liable to a penalty not exceeding forty shillings for each offence, to be recovered in the same manner in which any penalty under the Acts relating to factories and workshops is recoverable. It is admitted on all hands that the mining industry is passing through a depression hitherto unparalleled in intensity, and that there is practically little, if any, margin between the cost of production and the selling price. While, in common with other commodities, the value of coal and ironstone has fallen continuously for the past few years, the cost of raising has been materially increased by the operation of a variety of influences, amongst which the incidence of legislative enactments has been considerable. There is no doubt that the recent Coal Mines Regulation Act has increased the cost of getting minerals, and while we shall ever be ready to welcome restrictions or provisions which in their operation secure a higher degree of safety in the dangerous occupation of mining, we cannot but deprecate, in the interests of all concerned, the passing of measures which, while not actually attaining this end, hamper and impede the development of a national industry, and constitute a deterrent to competition with our foreign rivals. The promoters of the Bill under review cannot contend that its object is to increase the safety of working minerals; it appears rather to be framed with a view to a general and wholesale restriction of output under the authority of the State. We do not think such a scheme comes within the province of the Legislature, and the disastrous results which would follow the operation of this Bill are obvious. In order to meet the increased tension of standing charges, colliery proprietors have been forced to enlarge their output, and the effect of a sudden restriction in this respect would simply be to close many of the pits. The question then arises as to the necessity or advisability of this proposal in the interests of working colliers. The present custom is for shifts of men to be lowered and raised at times so arranged as to leave eight hours per day for actual work in the mines, sufficient time being allowed for colliers to reach their working face, to consult the firemen, and other necessary preliminaries. Striking an average, it may be said that half an hour elapses from the time of leaving the surface to the commencement of actual work, and another half hour from the cessation of work to the time of arriving at the bank, and the effect of this measure would, consequently, be to reduce the aggregate output of the country by at least 12 per cent., and the hours of work from eight to seven. It should be unnecessary to point out that the weekly amount of wages now possible to be earned by colliers would be necessarily reduced in proportion to the decrease of their productive capacity. We would also point to the friction which the smallest infraction of this law might cause between employers and employed. Under all the circumstances of the case, we have little fear as to the fate of this measure when public opinion generally, and that of the mining community, inclusive of colliery owners and miners, in particular, has been directed to its provisions; but there may be a danger of a short Bill of this description being passed through the House of Commons without due consideration being given to the enormous interests involved.

THE EMPLOYERS' LIABILITY BILL.

The Employers' Liability Bill, which has now passed through the second reading stage, is intended to replace the Act which was enacted in 1880, and marks the advance in public opinion on the subject since that date. When the original Act was passed a great many erroneous ideas on the subject prevailed, and an unnecessary fear of its probable consequences caused it to be so hampered in some of its requirements that a considerable amount of dissatisfaction with its provisions was engendered among the working classes. The definition of "common employment," as given in the Act, was looked upon as a mere subterfuge for sheltering employers from their just liability, and this opinion was openly stated by Mr. Broadhurst in his place in Parliament. On this, as well as on several other points in the Bill, the Government wisely took a position of compromise. The Home Secretary stated that while it was fair enough to call on employers to provide plant and machinery in good condition, it could not be considered right to hold them liable for the casual negligence or misconduct of a servant. He therefore proposed to make an alteration in the present interpretation clause, so that "common employment" should not include those cases in which employers delegate to managers the task of superintendence and control. This part of the subject is, however, likely to be further discussed in the committee stage of the Bill.

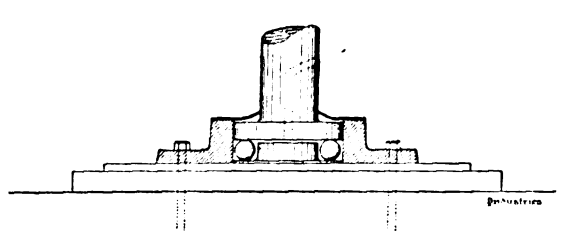
The next important question which was discussed dealt with the principle of contracting out of the Act. As we mentioned at the time, the Committee on Employers' Liability which sat last year agreed to recommend prohibition of contracting out, except on condition that some system of insurance were provided, not merely against accidents for which masters would be liable, but also against accidents of all kinds. The framers of the new Bill have adopted this proposal, and, moreover, have guarded it with many precautionary measures. It provides, for example, for all insurance schemes being submitted to the Board of Trade, so that their soundness and adequacy may be certified, and it makes employers liable for the solvency of the fund, and for the correctness of the actual calculations, so as to allow the claims of injured workmen being met.

The Bill proposes to extend the provisions of the Employers' Liability Act to seamen, subject to certain conditions. When this matter was being discussed in 1880, the Legislature was of opinion that the conditions of service at sea and service on land were so different that it would not be fair to bring ship owners under the Act. But in these days public opinion is subject to very rapid changes, and recently it has been said in various quarters that at least some of the principles of the statute should no longer be withheld from sailors. The Royal Commission on Loss of Life at Sea last year, however, reported that "the general results of the Act of 1880 in respect to other employments, by inducing greater care by employers and their agents or servants, have been so satisfactory that they felt no hesitation in recommending its extension to seamen, subject to some modifications to meet the special circumstances of ships." The Bill provides that ship owners shall be liable for accidents in home ports, just as manufacturers are liable in works; but when accidents occur in other ports there shall be no liability, unless the injury has been caused by a defect in the condition of the ship or its equipments. It proposes that "notice" may be given at any time before the expiration of three months from the termination of an engagement or voyage during which the injury was sustained, and that an action may be "commenced" at any time before the expiration of six months, or, in case of death, twelve months from the termination of that voyage or engagement.

We must confess that we have no great liking for the interference of Government between employers and employed more than is absolutely necessary, and we generally sympathise with the remarks of the Home Secretary when he said that by legalising the systems proposed in the Bill, he hoped that employers and employed may gradually be led to adopt a general scheme of insurance which would render all appeals to legal methods unnecessary. This should be the aim of all legislation. Unnecessary governmental interference simply irritates men who think for themselves, while it binds in official red tape those who do not. Wise legislation will endeavour to encourage a voluntary co-operation between employers and employed, which, while strengthening the consciousness of the rights of each, will also show that those rights can only be enforced when the one party recognises the just claims of the other.

THE WHITWORTH INSTITUTE.

In December last the residuary legatees of the late Sir Joseph Whitworth made certain proposals to the Manchester City Council for the purchase of a plot of land for a park and for the erection of a museum and technical school. The Council appointed a committee to confer with the residuary legatees for the purpose of maturing the scheme, and on Wednesday last they submitted a report of their deliberations. The legatees have still further extended their handsome offers, and it appears that no trouble or expense is to be spared in affording the rising generation the advantages of a complete course of technical education. The scheme proposed is most comprehensive, and the fact that Sir Joseph Lee, Sir H. Roscoe, Sir J. J. Harwood, Mr. William Agnew, Mr. Oliver Heywood, and Mr. Thomas Ashton are on the Whitworth Committee is, we think, a sufficient guarantee that the scheme will be carried out on broad, generous lines. In the first place, a plot of land in Oxford Road, commonly called Potter's Park, twenty acres in extent, and valued at £47,000, is to be acquired for the purposes of a pleasure park; on part of it is to be erected a museum of arts and industries, in which will be exhibited a collection of specimens of the fine and industrial arts, and the commercial productions of the chief countries of the world. Another part of the proposals relates to the present School of Art. The building is to be considerably enlarged, in order that instruction may be given in modelling, mechanical drawing, and architectural design, and in embroidery and art needlework. The present technical school is also much too limited for its requirements, so that the committee propose to erect an entirely new building on a more extensive site, and to develop the resources of the school in other ways. Instruction will be afforded in the industrial sciences, with the use of machinery, apparatus, tools, physical and chemical laboratories, museum and library, and also in mechanical and other drawing, in modern languages, and in various branches of commercial education. It is also intended to establish several manual training schools in different parts of the city, which may form a link between the public elementary schools and the proposed Central Technical School.



Such an extensive scheme will require a large amount of capital with which to commence operations; but there is little doubt that it will be found.

Letters to the Editor.

THE REPORT OF THE RESEARCH COMMITTEE ON FRICTION.

To the Editor of "Industries."

Sir,—Referring to the recent discussion on "Friction" at the last meeting of the Institution of Mechanical Engineers, and of which you have published a report, I beg to send you herewith a sketch and short description of a method I have introduced for supporting heavy vertical and thrust shafts, in lieu of ordinary footstep bearings. The system, briefly described, consists in extending the base of the shaft, and causing it to revolve on balls or rollers confined in

an oil chamber. The balls have a circular traverse, are made smooth and hard, and their pathway is turned. The bearing is covered in with a cap through which oil can be supplied, or in certain cases a hole can be drilled up the shaft for the same purpose. By extending the base of the shaft the pressure is distributed, and by using the balls or friction rollers in an oil bath the friction is very largely reduced. I may add that I have had a vertical shaft, carrying several tons, running for some time, without giving any trouble whatever.

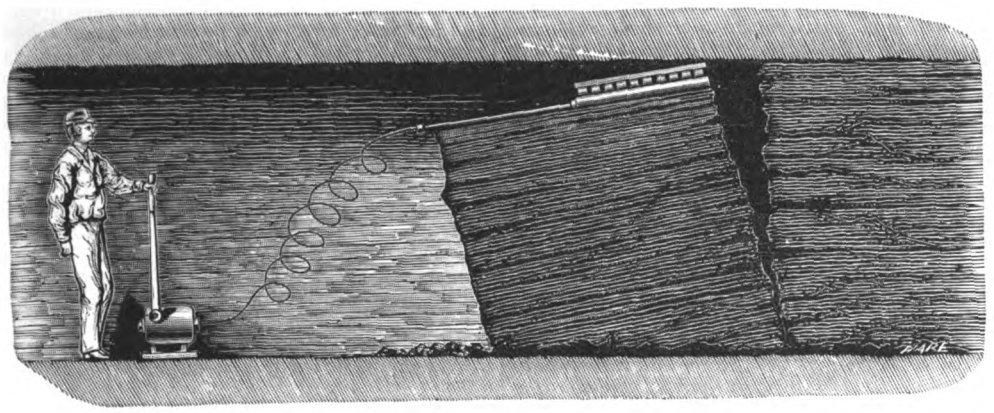
Yours, &c.,

London, E.C., 1st June, 1888. M. Powis Bale.

PROPOSED FUEL TESTING STATION FOR LONDON.

To the Editor of "Industries."

Sir,—Will you allow me to put before your readers the following proposition for the establishment of such a station, the desirability of which has been much impressed upon me within the last few years? So far as I know, there does not exist anything of the kind in this country, whereas on the Continent coals can be tested for their evaporative power, the gases of combustion analysed, and all the results carefully reported on by experts. I subjoin a few details of the proposed station, with probable cost. It should, I consider, be placed on a perfectly independent footing, and managed by experts, under a small committee appointed by those who assist with money or otherwise. It might follow generally the lines of existing coal testing stations, but with all modern improvements.



In this country it is remarkable that neither the sellers of coal take the trouble to find out how much heat they are offering, nor the purchasers how much they are getting for their money, and this notwithstanding the hundreds of million tons of coal changing hands yearly. Colliery owners and coal merchants, as well as the large consumers, know very little about coal calorimeters, although the former sell so much heat, and the latter try to utilise it to the best advantage. How few of the latter weigh their coal regularly, or keep any weekly record of the quantities of ashes and clinkers, to find out how much dirt and incombustible matter they are paying for. How few know what it costs them in fuel to evaporate one thousand gallons of water into steam, which is one of the best standards of comparison in a given district.

Locality.—The station might be in close proximity to a river, canal, or railway station, so that the coals could be delivered easily and cheaply, and the steam allowed to escape under pressure without causing annoyance. A small piece of land doubtless could be obtained in such a situation at a low rent. The boiler shed should be about 35ft. by 20ft., with a small additional shed for storing the fuel.

Cost.—It would be desirable to allow at least £700 for a start to cover the cost of the boiler shed, chimney, 20 h.p. boiler (if such were considered large enough), and the special arrangements for measuring the feed water with tanks, scales, feed pump, injector, gas and coal analysing apparatus, calorimeters, &c. Seeing that until the objects of the station become known it would probably not pay expenses, the help of guarantors would no doubt be necessary.

HYDRAULIC COAL GETTING MACHINE.

Yearly Expenses.—The charge for testing and reporting upon each combustible would probably more than cover eventually the salaries of a technical manager, his assistant, and the stoker. Some arrangement might possibly be made by which the manager and his assistant should only attend when required, at any rate at first, in order to diminish expenses. The station would require to be advertised and made known in various ways. Colliery owners would, no doubt, find it to their advantage to have their different kinds of coal tested and reported upon, so as to offer them to their customers with their ascertained heating value or evaporative power. Large consumers of coal (railway companies, water works, and others) should know the heating value of the coal they are paying for, and the percentage of incombustibles.

I now add a few notes on the temporary and permanent experimental heat stations known to me. (1) The earliest fuel testing station was established in 1847, at Brix, in Germany. (2) Sir H. de la Beche and Dr. Lyon Playfair made a series of experiments before the year 1851 with different coals suitable for the navy. These trials were conducted near London under a small marine boiler at atmospheric pressure. (3) At the English Government dockyards various interesting experiments have been made under small marine boilers, and the results published in Blue Books. (4) Messrs. Armstrong, Londridge, & Richardson published in 1858 an account of some valuable experiments they had made of the steam coals of the Hartley district of Northumberland, under a small marine boiler, for the local steam colliery association. (5) At Wigan, many excellent experiments were made by Messrs. Richardson and Fletcher about 1867, to test the value of Lancashire and Cheshire steam coals for use in marine boilers. The water was evaporated under atmospheric pressure from a small marine boiler. This station was afterwards abolished. (In none of the above do the gases of combustion appear to have been analysed.) (6) A fuel testing station was working at Danzig, in 1863. (7) An important station was opened at Brieg on the Oder by the colliery owners of Lower Silesia, in April, 1878, with the primary object of testing the value as fuel of the important coal seams of that province. After working with the most satisfactory results for two years, and establishing the superiority of the Lower Silesian coal, the experiments terminated in 1880. The testing boilers had each 40 sq. m. of heating surface. Gases and coals were analysed.

Existing Continental Stations.—(8) The Imperial Naval Administration Coal Testing Station at Wilhelmshaven, Germany, was established in 1877. (9) Dr. Bunte's Coal Testing Station, erected at Munich about 1878, particulars of which have been published in Proceedings Inst.C.E., Vol. 73. Here some hundreds of trials have been reported on and published, much valuable work has been done, and many fuels tested, including coals of the Ruhr valley, Saar basin, Saxon and Bohemian coal fields, and those of Silesia and Upper Bavaria. The boiler of the station has about 450 sq. ft. of heating surface. The gas and coals are analysed, and all particulars carefully noted. It is one of the most complete stations I have seen. (10) In Belgium, near Brussels, there is a Government station for testing fuels, under the administration of the Belgium State railways. Locomotive boilers are used. The establishment has been at work for the last two years; but no results are published, as they are considered the property of the Government. Private firms can, however, have their coals tested and reported upon. (11) The Imperial Marine Station at Danzig. (12) The Boiler Insurance Company at Magdeburg.

The above is a slight outline of the work already done in this direction. With the view of obtaining the opinions of those interested in starting a fuel testing station, I ask you kindly to give this letter publicity. If the necessary sum can be raised, we may hope to have before long a practical and useful establishment in London, and to gain from it many interesting practical results respecting the combustion of fuels.

Yours, &c.,

BRYAN DONKIN, JUN.

Bermondsey, London, S.E., 1st June, 1888.

HYDRAULIC COAL GETTING MACHINE.

ON Tuesday last, we had an opportunity of witnessing some interesting experiments at Kiveton Park Colliery, near Sheffield, in connection with a new hydraulic coal getting machine, which is the patented invention of Messrs. Roberts-Horsfield & Porter, and made by the North London Engineering Works, Caledonian Road, London, N. Briefly described, this machine consists of a steel bar containing a number of circular cavities into which are fitted a series of small rams, which are forced out simultaneously by water pressure. The lower end of each ram is attached to another bar by screws, while the upper end is fitted with an ordinary cup leather fixed by a screw and washer. The whole of the rams are actuated by water supplied through a flexible copper tube from a force pump, as shown in our illustration. The mode of operation is somewhat as follows: After a bore hole has been made in the upper part of the working face large enough to allow the coal getting machine to be inserted, the under part of the face is cut away and supported by temporary sprags. As soon as the bottom has been sufficiently removed, the sprags are taken away and the pump is started. The water gradually forces the rams out —a maximum distance of $1\frac{3}{4}$in.—and exerts, if necessary, a combined pressure of 70 tons, which has been found sufficient in every case to bring down the coal. The coal brought down is not crushed or broken, and much less slack is produced than in the case of blasting, while the men can work in absolute safety. The amount of coal displaced at each operation averages from 14 tons to 24 tons, and the operation of pumping takes on an average four minutes. The weight of the press used in these experiments was only 40lb. In an early issue we hope to be able to give a further description of this invention, which, judging from the experiments thus far carried out, would appear to give extremely satisfactory results.

THE SOCIETY OF TELEGRAPH ENGINEERS AND ELECTRICIANS.

AT the last meeting of this Society, Professor S. P. Thompson read a paper on "The Influence Machine from 1788 to 1888." The author stated that on the 5th of June, 1788, Nicholson's revolving doubler was announced to the Royal Society, in a letter from the inventor to the President, Sir Joseph Banks, so that the 5th of June of the present year would be the hundredth anniversary of the invention of the influence machine. The existence of electrical influence was discovered in 1753 by John Canton, of Stroud, a man of great ability, but one who, like many men of exceptional genius, lived to a great extent apart from the other scientific men of his day, with the result that his ideas were not expressed in the ordinary scientific terminology of the time, and it was, therefore, somewhat difficult to understand his more or less obscure explanations. He accounted for the phenomenon which he observed by assuming the existence of a kind of electrified atmosphere surrounding every charged body. Further researches in the same direction very soon followed. Franklin, Wilkie, and Epinus were among his immediate successors in this field, and the results were expressed by them in terms of the mathematical conception of direct action at a distance. The Italian physicist, Beccaria, was the first to observe that the behaviour of a body carrying a certain charge depended on the neighbouring bodies, and that by varying the positions of the latter, it could be made to act in the same manner as if its charge had been either increased or diminished. To this action he gave the latin name *Vinder*, for which it was difficult to find an intelligible English equivalent. In 1762 Wilkie discovered the principle of the electrophorus. His instrument consisted of a glass table having on its under surface a piece of cardboard, to which an electric charge could be given. Another insulated sheet of cardboard, above, and parallel to the glass, could be moved towards or away from it, by means of cords and pulleys. Wilkie found that a charge could be communicated to the upper sheet of cardboard by simply lowering it down close to the glass, touching it, and then raising it again. Volta afterwards re-discovered the electrophorus in its present well known form of a plate covered with a sheet of some resinous substance, and a metal plate or cover, attached to a glass handle. In 1778 Volta devised a condensing arrangement which he used in conjunction with the electrophorus, as well as independently. In 1780 Lichtenberg, whose name is familiar in connection with the well known Lichtenberg figures formed by a mixture of red lead and sulphur dusted on a resinous surface, previously touched at different points with a charged body, devised a double or reciprocal electrophorus. This consisted of a board about 2ft. long by 1ft. broad, provided with a wooden rim and covered with a compound of pitch and turpentine. One end of the surface was electrified by friction, a metallic plate was placed on this part and touched, by which it became oppositely electrified. It was then removed by means of an insulating handle and placed upon the other end of the surface, communicating a charge opposite to the first. While there it was touched, which gave it a charge similar to that at the other end of the surface. It was then replaced upon this end, increasing its charge, then touched, by which it received an increased opposite charge, and by continuing the series of operations, the opposite charges at the ends of the surface, and therefore those obtainable in the metal plate by induction, could be increased to a considerable extent.

In the meantime Erasmus Darwin, the father of Charles Darwin, had become interested in Volta's electrophorus, and in 1778 he made an attempt to perform a series of operations similar to those of Lichtenberg by mechanical means. The author had found many allusions to Darwin's apparatus, but for a long time he was unable to find any accurate description of it, as it did not appear to have been published; but ultimately he was successful in discovering Darwin's original notes and drawing, bearing date 1778. The apparatus consisted of a fixed glass disc with a pair of movable metal discs, one on each side of it, which could be made to approach and recede from the glass by means of crank levers. This apparatus was communicated to Nicholson through a Mr. Partington, and evidently gave him the idea of the revolving doubler. In the meantime, in the year 1787, Bennett read a paper at the Royal Society on an electrical doubler for the smallest possible charges to such an extent as to render them perceptible by means of an ordinary electroscope. His apparatus consisted merely of three metal discs attached to insulating handles, by means of which considerable opposite charges could be obtained by successive inductive action from a small initial charge; but the charge was certainly not doubled each time, and there was no arrangement for effecting the operations automatically. Its method of action was as follows: Calling the plates A B and C, a charge, say + 1 was given to A; C was then placed near it, and earth connected, so receiving by induction a charge slightly less than −1, but which for simplicity we may call −1. C is then placed close to B, and the latter earth connected, thus receiving a charge + 1. B is then placed in contact with A and brought close to C, which is earth connected, and receives a charge −2, and this series of operations is repeated as often as desired.

Within the next twelve months Tiberius Cavallo, an Italian physician living in London, devised an arrangement consisting of four metal plates placed vertically on insulating rods. One plate was fixed at one end of the stand and received the initial charge; two were at the other end, forming a condenser, and a fourth plate could be moved by a lever to and fro. The inventor and others engaged in these researches were greatly puzzled at finding that this instrument would develop a charge without any initial electrification, and they concluded that a charge was produced whenever two metal plates were brought into contact. Nicholson's instrument was the next, and consisted of a metal disc fixed at the end of a glass rod, and capable of rotating in its own plane about an axis passing through the centre of the rod, in front of a pair of plates fixed in a plane parallel to that of the revolving plate, and close to it, on opposite sides of the axis. The requisite contacts were made automatically by means of springs. Calling A and B the two fixed plates, and C the revolving one, an initial charge, say positive, is given to one of the fixed plates. When C comes opposite to A, A and B are connected with each other, and C is earth connected, receiving a negative charge by induction. When C comes opposite to B, A and B are disconnected, and B is earth connected, receiving a positive charge by induction from C. When C again comes opposite to A, the positive charge on B is drawn to A, and C, being again earth connected, receives a stronger negative charge, and so the operation may be continued until sparking takes place between the fixed and movable plates. This instrument is also found to excite itself without initial charge. An objection which

Digitized by Google

was urged against it as soon as it was brought out was that, owing to the discs approaching edgeways, there would be a great superficial density on the edges of the discs, and a consequent loss of electrification, and also that there would be a loss from the springs. In 1798 Bohnenberger, a German pastor, published a book in which he described a number of different patterns of doublers acting on a similar principle. In 1823 Sir Francis Ronalds devised a doubler in which the moving plate had a pendulous motion, and the two fixed plates, as in Nicholson's instrument, were similarly charged. The instruments devised since then have all had the fixed plates oppositely charged, on Lichtenberg's plan, and the author calls them field plates, from their analogy with the field magnets of a dynamo.

In 1831 Belli devised an instrument of this kind. Two metal discs (Fig. 1) fixed to the ends of a glass stem

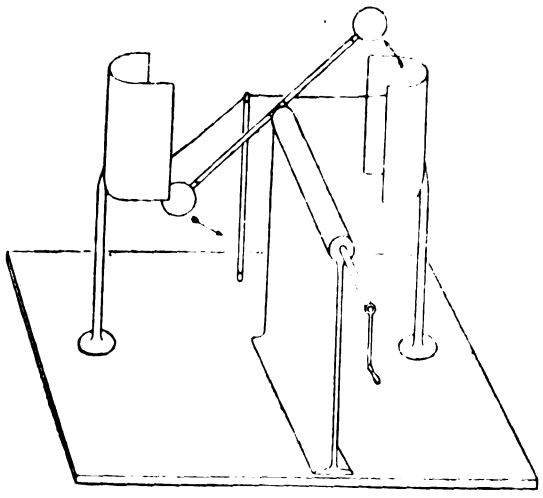

Fig. 1.—Belli, 1831.

passed between two field plates, and were earth connected just before passing out of their influence, and touched by collecting brushes just after entering, as in the modern influence machines.

In 1846 Svanberg devised another form of double electrophorus, which was described by Billet in 1851. From this time no further attempts were made to improve influence machines, until in 1860 Varley patented a machine in which a series of metal conductors or carriers were attached to a disc of vulcanite capable of rotation about an axis. The carriers passed between two pairs of insulated field plates, and when opposite them they were touched by earth connected conductors. Spring contacts connected the carriers with the field plates just as they entered within their influence. When a small initial charge was given to one of the field plates, the other field plate, therefore, became oppositely electrified, and the opposite charges on the two field plates could in this way be increased until the limit of insulation was reached.

Shortly after, Toepler invented a machine in which single field plates were used, and which is represented diagrammatically in Fig. 2. Simultaneously, Holtz brought out a machine which consisted of two glass plates, one

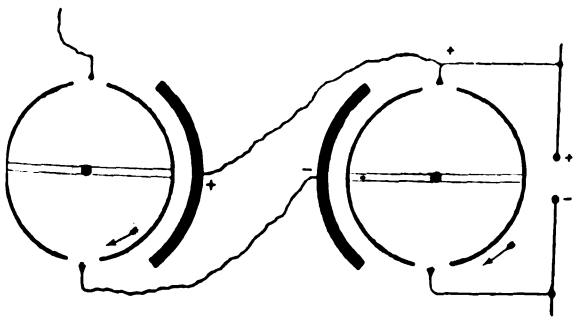

Fig. 2.—Toepler, 1865.

fixed and one rotating. Two windows are cut in the fixed plate on opposite sides of the axis. These windows are difficult to cut, and make the plate rather costly. Two pieces of varnished cardboard which act as the field plates are attached to the fixed plate on the side opposite to the rotating plate above one window and below the other, and they are furnished with narrow tongues which project through the windows and nearly touch the revolving plate, which must turn in the direction opposite to that in which the tongues point. In front of the rotating plate, opposite the forward edges of the field plates, is a diagonal metallic conductor, provided at its ends with metallic combs facing the moving disc. Two horizontal insulated metal combs joined to metal rods terminating in metal balls face the rotating disc on each side, and form the discharging apparatus. The action of the machine is as follows: A small charge, say positive, being given to one of the field plates, the charge, carried forward by the glass, acts inductively through the glass on the comb of the diagonal conductor which it first passes. The comb being thus negatively charged, discharges a negatively electrified wind upon the front surface of the rotating plate, while the repelled positive passes to the comb at the other end of the diagonal conductor, so that positive electrification is here communicated to the glass. This acts by induction on the second field plate, charging the point opposite the comb negatively, and repelling positive to its further extremity, viz., the tongue, whence it is slowly discharged on to the back of the rotating plate. As the plate revolves this charge is carried round until it gets opposite the tongue of the other field plate, into which it discharges, and so increases its positive charge. The negative charge acts in a similar manner on the other comb, increasing its positive discharge, and drawing electricity through the diagonal conductor. The two combs on the diagonal conductor therefore throw opposite charges on to the glass, and the back of the rotating plate is at the same time similarly charged; and the latter charges, carried round by the glass, increase the charges on the field plates. The charges thrown upon the front surface of the rotating disc from the combs of the diagonal conductor are collected by the horizontal combs of the discharging apparatus. The machine was improved by Poggendorff by the introduction of two fixed plates in the centre, with a rotating one on each side. Holtz devised a second form of machine in which the fixed plate and paper field plates were dispensed with, and two moving plates rotating in opposite directions were employed.

In 1868 Sir William Thomson, without knowing of what had been already done, devised his replenisher, which was similar in action to Varley's machine. In 1880 Voss devised a machine which was a sort of combination of a Toepler and a Holtz machine. The author also exhibited a specimen of Sir William Thomson's mouse-mill replenisher, in which metal carriers and multiple field

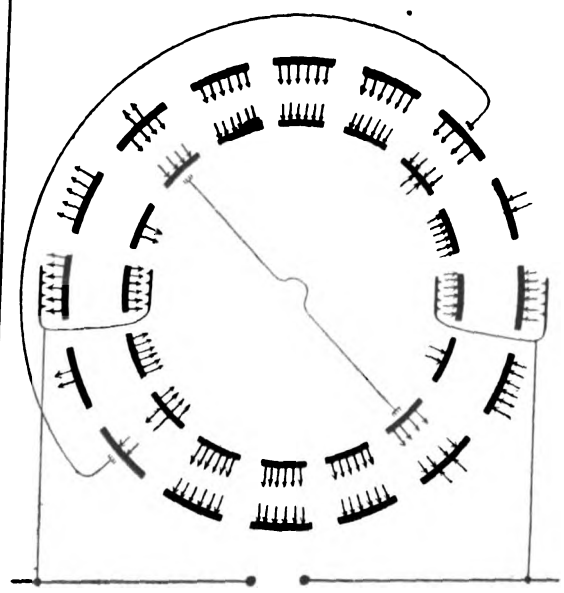

Fig. 3.—Wimshurst, 1881.

plates are used, and he pointed out the exact analogy which this instrument bears to a dynamo. The author then explained the action of Sir William Thomson's water dropping electrophorus. Two pairs of insulated metal cylinders are respectively connected with the internal coatings of two Leyden jars. Two of these, the inductors, are simply cylinders open at each end, while the receivers consist of similar cylinders partially closed in the middle by small funnels opening downwards, and with their narrow mouths a little above the centres of the cylinders. An inductor and a receiver are in connection with each jar, the inductor of the first jar being vertically over the receiver of the second, and *vice versa*. Two fine streams of water from earth connected vessels are allowed to fall through the inductors, which are so placed that the streams break into drops near their centres, and these drops, passing through the inductors, fall into the funnels of the receivers. If a small positive charge is given to the first jar, its inductor produces a negative charge on each drop as it forms; this negative charge is almost entirely given up to the receiver, as the stream breaks into drops at the mouth of the funnel which is in the interior of a conductor. The negative electrification thus produced in the second jar acts through its inductor on the receiver of the first jar and augments its positive charge, and this in turn increases the negative electrification of the second jar, and so the process continues.

The author also showed a compact form of this apparatus which he had devised, and had recently exhibited to the Physical Society. He then went on to state that Mr. Wimshurst, trying to find a substitute for the windows in the Holtz machine, made the fixed plate in two sections, each rather less than a semi-circle, so that when put together there was a space between, and behind this he pasted the paper field plates. He then determined to make both the plates revolve in opposite directions, and was thus led to the Wimshurst machine in its present form, consisting of two glass plates rotating in opposite directions. Each plate carries a number of strips of tin foil which serve both as field plates and carriers, or armatures, as Professor Thompson calls them, to indicate their analogy with the armature of a dynamo. At the front and back are a pair of uninsulated diagonal conductors, and on each side is a pair of insulated collecting combs connected with the discharging apparatus. Fig. 3 is a diagrammatical view of this machine. The arrows show the character of the inductions, being directed to the plate for positive and from the plate for negative charges. As each armature passes the opposite charged carrier of the other disc, the latter acts as a field plate and induces a charge in the former, which itself acts as field plate to the other as armature. If combs only are used in an influence machine, it will not excite itself, and, on the other hand, if brushes only are used, it is liable to reverse on discharge. Brushes should therefore be used for neutralising, and combs for collecting the charges, which arrangement has been adopted in the Wimshurst machine. The e.m.f. of influence machines is practically constant, whatever the speed, but the internal resistance diminishes as the speed is increased, which shows that a series of moving charges is equivalent to a current. The author also exhibited some specimens of Clarke's and other gas lighters, in which the spark producing apparatus consists of small influence machines. The following is a list of inventors in chronological order:—

Canton	1753	Goodman	1841
Wilkie	1762	Svanberg	1846
Volta	1776-82	Billet	1851
Darwin	1778		
Lichtenberg	1780	Varley	1860

The discussion was opened by Professor Ayrton, who thought that the author, while giving an admirable account of the development of the influence machine, had not dwelt sufficiently on the remarkable number of times that re-invention, in ignorance of previous work, had taken place. Sir William Thomson's replenisher was not a development of any known influence machine, for in the year 1867 Sir William did not know that such a thing existed. The object he had in view was to devise a machine capable of charging the ink of a syphon recorder, and at the same time be worked easily enough to be driven by clock work, instead of requiring continuous manual labour, as one of the old frictional machines would. It was not until Mr. Bottomley and he himself had been asked by Sir William to consult the patent registers, when he was preparing to patent the replenisher, that he heard of Varley's machine, although Varley had been his partner. He did not think the use of combs overcame the difficulty of reversal, which was the great difficulty in Thomson's original machine; and he stated that a Wimshurst machine, in use at the Central Institution, was frequently found to reverse. This might be due to its small capacity. He pointed out the very high efficiency of influence machines relatively to the old frictional machines.

Mr. Mordey asked why it was necessary for each charge to be carried so far round unchanged, as was shown by a diagram exhibited.

The author, in replying, said that a Wimshurst machine, with both brushes and combs in the discharge, used always to reverse, but no longer did so after the brushes had been entirely replaced by combs. In the case of the large 8-plate Wimshurst machine which was exhibited, he had been unable to get a reversal until Mr. Wimshurst had shown him a way of doing it, by charging a Leyden jar from one side, putting the knobs together, then separating, and putting the charge in at the other side. In reply to Mr. Mordey's question, the author pointed out that if the range were diminished it would diminish the insulation, and therefore lessen the maximum length of spark obtainable from the machine.

Mr. Wimshurst expressed surprise at Professor Ayrton's finding that one of his machines reversed. He felt sure there must be something wrong with it, and he would examine it and point it out; for in his own experience he had never got a reversal, either with large or small machines.

NICOLA TESLA'S ALTERNATING CURRENT MOTOR.

In our issue of the 18th May, we gave an account of a very interesting investigation made by Professor Galileo Ferraris, of Turin, which had for its object the production of mechanical rotation by the electro-dynamic action of alternating currents. The fundamental principle of the apparatus devised by Ferraris, is a revolving resultant magnetic field produced by two coils, which carry alternating currents, and the axes of which are at right angles to each other. We said in our account of this investigation, that this principle may be applied in the construction of electricity meters to be used on an alternate current supply system, and possibly also in that of motors; though on this point we would not prophesy. It is significant of the enterprise and inventive skill of American electricians, that at the time these lines were being printed, Mr. Nicola Tesla brought before the American Institute of Electrical Engineers an actual solution of the problem which we on this side of the Atlantic merely foreshadowed as possible at some future time. The solution may perhaps not be perfect in its present form; but as far as it goes, it is a long step in the direction of applying alternating currents for motive power purposes, and as such it will be appreciated by those of our readers who are interested in the distribution of electricity from central stations. Owing to the importance of the subject, we give herewith Mr. Tesla's paper in full.

In the presence of the existing diversity of opinion regarding the relative merits of the alternate and continuous current systems, great importance is attached to the question whether alternate currents can be successfully utilised in the operation of motors. The transformers, with their numerous advantages, have afforded us a relatively perfect system of distribution, and although, as in all branches of the art, many improvements are desirable, comparatively little remains to be done in this direction. The transmission of power, on the contrary, has been almost entirely confined to the use of continuous currents, and notwithstanding that many efforts have been made to utilise alternate currents for this purpose, they have, up to the present, at least as far as known, failed to give the result desired. Of the various motors adapted to be used on alternate current circuits the following have been mentioned: (1) A series motor with subdivided field. (2) An alternate current generator having its field excited by continuous currents. (3) Elihu Thomson's motor. (4) A combined alternate and continuous current motor. Two more motors of this kind have suggested themselves to me: (1) A motor with one of its circuits in series with a transformer, and the other in the secondary of the transformer. (2) A motor having its armature circuit connected to the generator, and the field coils closed upon themselves. These, however, I mention only incidentally.

The subject which I now have the pleasure of bringing to your notice is a novel system of electric distribution and transmission of power by means of alternate currents, affording peculiar advantages, particularly in the way of motors, which I am confident will at once establish the superior adaptability of these currents to the transmission of power, and will show that many results heretofore unattainable can be reached by their use: results which are very much desired in the practical operation of such systems, and which cannot be accomplished by means of continuous currents.

Before going into a detailed description of this system, I think it necessary to make a few remarks with reference to certain conditions existing in continuous current generators and motors, which, although generally known, are frequently disregarded.

In our dynamo machines, it is well known, we generate alternate currents which we direct by means of a commutator—a complicated device, and, it may be justly said, the source of most of the troubles experienced in the operation of the machines. Now, the currents so directed cannot be utilised in the motor, but they must—again by means of a similar unreliable device—be re-converted into their original state of alternate currents. The function of the commutator is entirely external, and in no way does it affect the internal working of the machines. In reality, therefore, all machines are alternate current machines, the currents appearing as continuous only in the external circuit during their transit from generator to motor. In view simply of this fact, alternate currents would commend themselves as a more direct application of electrical energy, and the employment of continuous currents would only be justified if we had dynamos which would primarily generate, and motors which would be directly actuated by such currents.

But the operation of the commutator on a motor is twofold—firstly, it reverses the currents through the motor; and secondly, it effects, automatically, a progressive shifting of the poles of one of its magnetic constituents. Assuming, therefore, that both of the useless operations in the system, that is to say, the directing of the alternate currents on the generator, and reversing the direct currents on the motor, be eliminated, it would still be necessary, in order to cause a rotation of the motor, to produce a progressive shifting of the poles of one of its elements, and the question presented itself, how to perform this operation by the direct action of alternate currents. I will now proceed to show how this result was accomplished.

In the first experiment a drum armature was provided with two coils at right angles to each other, and the ends of these coils were connected to two pairs of insulated contact rings as usual. A ring was then made of thin insulated plates of sheet iron and wound with four coils, each two opposite coils being connected together so as to produce free poles on diametrically opposite sides of the ring. The remaining free ends of the coils were then connected to the contact rings of the generator armature so as to form two independent circuits, as indicated in Fig. 9. It may now be seen what results were secured in this combination, and with this view I would refer to the diagrams Figs. 1 to 8a. The field of the generator being independently excited, the rotation of the armature sets up currents in the coils $c\,c$, varying in strength and direction in the well known manner. In the position shown in Fig. 1 the current in coil c is nil while coil c^1 is traversed by its maximum current, and the connections may be such that the ring is magnetised by the coils $c\,c$, as indicated by the letters N S in Fig. 1a, the magnetising effect of the coils $c\,c$ being nil, since these coils are included in the circuit of coil c.

In Fig. 2 the armature coils are shown in a more advanced position, one-eighth of one revolution being completed. Fig. 2a illustrates the corresponding magnetic condition of the ring. At this moment the coil c generates a current of the same direction as previously, but weaker, producing the poles n_1 s, upon the ring; the coil c also generates a current of the same direction, and the connections may be such that the coils $c\,c$ produce the poles $n\,s$, as shown in Fig. 2a. The resulting polarity is indicated by the letters N S, and it will be observed that the poles of the ring have been shifted one-eighth of the periphery of the same.

In Fig. 3 the armature has completed one-quarter of one revolution. In this phase the current in coil C is a maximum, and of such direction as to produce the poles N S in Fig. 3a, whereas the current in coil c_1 is nil, this coil being at its neutral position. The poles N S in Fig. 3a are thus shifted one-quarter of the circumference of the ring.

Fig. 4 shows the coils $c\,c$ in a still more advanced position, the armature having completed three-eighths of one revolution. At that moment the coil c still generates a current of the same direction as before, but of less strength, producing the comparatively weaker poles $n\,s$ in Fig. 4a. The current in the coil c is of the same strength, but of opposite direction. Its effect is, therefore, to produce upon the ring the poles n_1 and s_1, as indicated, and a polarity N S results, the poles now being shifted three-eighths of the periphery of the ring.

In Fig. 5 one-half of one revolution of the armature is completed, and the resulting magnetic condition of the ring is indicated in Fig. 5a. Now, the current in coil c is nil, while the coil c yields its maximum current, which is of the same direction as previously; the magnetising effect is therefore due to the coils $c\,c$ alone, and referring to Fig. 5a, it will be observed that the poles N S are shifted one-half of the circumference of the ring. During the next half revolution the operations are repeated, as represented in the Figs. 6 to 8a.

A reference to the diagrams will make it clear that during one revolution of the armature the poles of the ring are shifted once around its periphery, and each revolution producing like effects, a rapid whirling of the poles in harmony with the rotation of the armature is the result. If the connections of either one of the circuits in the ring are reversed, the shifting of the poles is made to progress in the opposite direction; but the operation is identically the same. Instead of using four wires, with like result, three wires may be used, one forming a common return for both circuits.

This rotation or whirling of the poles manifests itself in a series of curious phenomena. If a delicately pivoted disc of steel or other magnetic metal is approached to the ring it is set in rapid rotation, the direction of rotation varying with the position of the disc. For instance, noting the direction outside of the ring, it will be found that inside the ring it turns in an opposite direction, while it is unaffected if placed in a position symmetrical to the ring. This is easily explained. Each time that a pole approaches it induces an opposite pole in the nearest point on the disc, and an attraction is produced upon that point; owing to this, as the pole is shifted further away from the disc, a tangential pull is exerted upon the same, and the action being constantly repeated, a more or less rapid rotation of the disc is the result. As the pull is exerted mainly upon that part which is nearest to the ring, the rotation outside and inside, or right and left, respectively, is in opposite directions. When placed symmetrically to the ring, the pull on opposite sides of the disc being equal, no rotation results. The action is based on the magnetic inertia of the iron; for this reason a disc of hard steel is much more affected than a disc of soft iron, the latter being capable of very rapid variations of magnetism. Such a disc has proved to be a very useful instrument in all these investigations, as it has enabled me to detect any irregularity in the action. A curious effect is also produced upon iron filings. By placing some upon a paper, and holding them externally quite close to the ring, they are set in a vibrating motion, remaining in the same place, although the paper may be moved back and forth; but in lifting the paper to a certain height, which seems to be dependent on the intensity of the poles and the speed of rotation, they are thrown away in a direction always opposite to the supposed movement of the poles. If a paper with filings is put flat upon the ring, and the current turned on suddenly, the existence of a magnetic whirl may be easily observed.

To demonstrate the complete analogy between the ring and a revolving magnet, a strongly energised electromagnet was rotated by mechanical power, and phenomena identical in every particular to those mentioned above were observed.

Obviously, the rotation of the poles produces corresponding inductive effects, and may be utilised to generate currents in a closed conductor placed within the influence of the poles. For this purpose it is convenient to wind a ring with two sets of superimposed coils, forming respectively the primary and secondary circuits. In order to secure the most economical results, the magnetic circuit should be completely closed, as shown in Fig. 10, and with this object in view the construction may be modified at will.

The inductive effect exerted upon the secondary coils will be mainly due to the shifting or movement of the magnetic action; but there may also be currents set up in the circuits in consequence of the variations in the intensity of the poles. However, by properly designing the generator, and determining the magnetising effect of the primary coils, the latter element may be made to disappear. The intensity of the poles being maintained constant, the action of the apparatus will be perfect, and the same result will be secured as though the shifting were effected by means of a commutator with an infinite number of bars. In such case the theoretical relation between the energising effect of each set of primary coils and their resultant magnetising effect may be expressed by the equation of a circle having its centre coinciding with that of an orthogonal system of axes, and in which the radius represents the resultant and the co-ordinates both of its components. These are then respectively the sine and cosine of the angle α between the radius and one of the axes (OX). Referring to Fig. 11 we have $r^2=x^2+y^2$; where $x=r\cos\alpha$, and $y=r\sin\alpha$.

Assuming the magnetising effect of each set of coils in the transformer to be proportional to the current—which may be admitted for weak degrees of magnetisation—then $x=Kc$ and $y=Kc^1$, where K is a constant and c and c^1 the current in both sets of coils respectively. Supposing further, the field of the generator to be uniform, we have for constant speed $c^1=K^1\sin\alpha$ and $c=K^1\sin(90°+\alpha)=K^1\cos\alpha$, where K^1 is a constant (see Fig. 12). Therefore

$$x=Kc=KK^1\cos\alpha;$$
$$y=Kc^1=KK^1\sin\alpha, \text{ and}$$
$$KK^1=r.$$

That is, for a uniform field the disposition of the two coils at right angles will secure the theoretical result, and the intensity of the shifting poles will be constant. But from $r^2=x^2+y^2$ it follows that for $y=0$, $r=x$; it follows that the joint magnetising effect of both sets of coils should be equal to the effect of one set when at its maximum action. In transformers and in a certain class of motors the fluctuation of the poles is not of great importance, but in another class of these motors it is desirable to obtain the theoretical result.

In applying this principle to the construction of motors, two typical forms of motor have been developed. First, a form having a comparatively small rotary effort at the start, but maintaining a perfectly uniform speed at all loads, which motor has been termed synchronous. Second, a form possessing a great rotary effort at the start, the speed being dependent on the load.

These motors may be operated in three different ways: (1) By the alternate currents of the source only; (2) by a combined action of these and of induced currents; (3) by the joint action of alternate and continuous currents.

The simplest form of a synchronous motor is obtained by winding a laminated ring provided with pole projections with four coils, and connecting the same in the manner before indicated. An iron disc having a segment cut away on each side may be used as an armature. Such a motor is shown in Fig. 9 The disc being arranged to rotate freely within the ring, in close proximity to the projections, it is evident that as the poles are shifted it will, owing to its tendency to place itself in such a position as to embrace the greatest number of the lines of force, closely follow the movement of the poles, and its motion will be synchronous with that of the armature of the generator; that is, in the peculiar disposition shown in Fig. 9, in which the armature produces by one revolution two current impulses in each of the circuits. It is evident that if, by one revolution of the armature, a greater number of impulses is produced, the speed of the motor will be correspondingly increased. Considering that the attraction exerted upon the disc is greatest when the same is in close proximity to the poles, it follows that such a motor will maintain exactly the same speed at all loads within the limits of its capacity.

To facilitate the starting, the disc may be provided with a coil closed upon itself. The advantage secured by such a coil is evident. On the start the currents set up in the coil strongly energise the disc, and increase the attraction exerted upon the same by the ring, and currents are generated in the coil as long as the speed of the armature is inferior to that of the poles. Considerable work may be performed by such a motor, even if the speed be below normal. The intensity of the poles being constant, no currents will be generated in the coil when the motor is turning at its normal speed.

Instead of closing the coil upon itself, its ends may be connected to two insulated sliding rings, and a continuous current supplied to these from a suitable generator. The proper way to start such a motor is to close the coil upon itself until the normal speed is reached, or nearly so, and then turn on the continuous current. If the disc be very strongly energised by a continuous current, the motor may not be able to start; but if it be weakly energised, or generally so that the magnetising effect of the ring is preponderating, it will start and reach the normal speed. Such a motor will maintain absolutely the same speed at all loads. It has also been found that if the motive power of the generator is not excessive, by checking the motor the speed of the generator is diminished in synchronism with that of the motor. It is characteristic of this form of motor that it cannot be reversed by reversing the continuous current through the coil.

The synchronism of these motors may be demonstrated experimentally in a variety of ways. For this purpose it is best to employ a motor consisting of a stationary field magnet, and an armature arranged to rotate within the same, as indicated in Fig. 13. In this case the shifting of the poles of the armature produces a rotation of the latter in the opposite direction. It results therefrom that when the normal speed is reached, the poles of the armature assume fixed positions relatively to the field magnet, and the same is magnetised by induction, exhibiting a distinct pole on each of the pole pieces. If a piece of soft iron is approached to the field magnet, it will at the start be attracted with a rapid vibrating motion produced by the reversals of polarity of the magnet; but as the speed of the armature increases, the vibrations become less and less frequent, and finally entirely cease. Then the iron is weakly but permanently attracted, showing that the synchronism is reached, and the field magnet energised by induction.

The disc may also be used for the experiment. If held quite close to the armature it will turn as long as the speed of rotation of the poles exceeds that of the armature; but when the normal speed is reached, or very nearly so, it ceases to rotate, and is permanently attracted.

A crude but illustrative experiment is made with an incandescent lamp. Placing the lamp in circuit with the continuous current generator, and in series with the magnet coil, rapid fluctuations are observed in the light, in consequence of the induced currents set up in the coil at the start; the speed increasing, the fluctuations occur at longer intervals, until they entirely disappear, showing that the motor has attained its normal speed.

A telephone receiver affords a most sensitive instrument;

when connected to any circuit in the motor the synchronism may be easily detected on the disappearance of the induced currents.

In motors of the synchronous type it is desirable to maintain the quantity of the shifting magnetism constant, especially if the magnets are not properly subdivided.

To obtain a rotary effort in these motors was the subject of long thought. In order to secure this result it was necessary to make such a disposition that while the poles of one element of the motor are shifted by the alternate currents of the source, the poles produced upon the other element should always be maintained in the proper relation to the former, irrespective of the speed of the motor. Such a condition exists in a continuous current motor; but in a synchronous motor, such as described, this condition is fulfilled only when the speed is normal.

The object has been attained by placing within the ring a properly subdivided cylindrical iron core wound with several independent coils closed upon themselves. Two coils at right angles are sufficient; but a greater number may be advantageously employed, as in Fig. 14. It results from this disposition that when the poles of the ring are shifted currents are generated in the closed armature coils. These currents are the most intense at or near the points of the greatest density of the lines of force, and their effect is to produce poles upon the armature at right angles to those of the ring, at least theoretically so; and since this action is entirely independent of the speed—that is, so far as the location of the poles is concerned—a continuous pull is exerted upon the periphery of the armature. In many respects these motors are similar to the continuous current motors. If load is put on, the speed, and also the resistance of the motor, is diminished, and more current is made to pass through the energising coils, thus increasing the effect. Upon the load being taken off, the counter e.m.f. increases, and less current passes through the primary or energising coils. Without any load the speed is very nearly equal to that of the shifting poles of the field magnet.

It will be found that the rotary effort in these motors fully equals that of the continuous current motors. The effort seems to be greatest when both armature and field magnet are without any projections; but as in such dispositions the field cannot be very concentrated, probably the best results will be obtained by leaving pole projections on one of the elements only. Generally, it may be stated that the projections diminish the torque, and produce a tendency to synchronism.

A characteristic feature of motors of this kind is their capacity of being very rapidly reversed. This follows from the peculiar action of the motor. Suppose the armature to be rotating, and the direction of rotation of the poles to be reversed. The apparatus then represents a dynamo machine, the power to drive this machine being the momentum stored up in the armature, and its speed being the sum of the speeds of the armature and the poles. If we now consider that the power to drive such a dynamo would be very nearly proportional to the third power of the speed, for this reason alone the armature should be quickly reversed. But simultaneously with the reversal another element is brought into action—viz., as the movement of the poles with respect to the armature is reversed, the motor acts like a transformer in which the resistance of the secondary circuit would be abnormally diminished by producing in this circuit an additional e.m.f. Owing to these causes the reversal is instantaneous.

If it is desirable to secure a constant speed, and at the same time a certain effort at the start, this result may be easily attained in a variety of ways. For instance, two armatures, one for torque and the other for synchronism, may be fastened on the same shaft, and any desired preponderance may be given to either one, or an armature may be wound for rotary effort; but a more or less pronounced tendency to synchronism may be given to it by properly constructing the iron core, and in many other ways.

As a means of obtaining the required phase of the currents in both the circuits, the disposition of the two coils at right angles is the simplest, securing the most uniform action; but the phase may be obtained in many other ways, varying with the machine employed. Any of the dynamos at present in use may be easily adapted for this purpose by making connections to proper points of the generating coils. In closed circuit armatures, such as used in the continuous current systems, it is best to make four derivations from equi-distant points or bars of the commutator, and to connect the same to four insulated sliding rings on the shaft. In this case each of the motor circuits is connected to two diametrically opposite bars of the commutator. In such a disposition the motor may also be operated at half the potential and on the three-wire plan, by connecting the motor circuits in the proper order to three of the contact rings.

In multipolar dynamo machines, such as use the converter systems, the phase is conveniently obtained by winding upon the armature two series of coils, in such a manner that while the coils of one set or series are at their maximum production of current, the coils of the other will be at their neutral position, or nearly so, whereby both sets of coils may be subjected simultaneously or successively to the inducing action of the field magnets.

Generally the circuits in the motor will be similarly disposed, and various arrangements may be made to fulfil the requirements; but the simplest and most practicable is to arrange primary circuits on stationary parts of the motor, thereby obviating, at least in certain forms, the employment of sliding contacts. In such a case the magnet coils are connected alternately in both the circuits; that is, 1, 3, 5 in one, and 2, 4, 6 in the other, and the coils of each set of series may be connected, all in the same manner, or alternately in opposition; in the latter case a motor with half the number of poles will result, and its action will be correspondingly modified.

The employment of multipolar motors secures in this system an advantage much desired and unattainable in the continuous current system, and that is, that a motor may be made to run exactly at a pre-determined speed, irrespective of imperfections in construction, of the load, and, within certain limits, of e.m.f. and current strength.

In a general distribution system of this kind the following plan should be adopted: At the central station of supply a generator should be provided having a considerable number of poles. The motors operated from this generator should be of the synchronous type, but possessing sufficient rotary effort to insure their starting. With the observance of proper rules of construction, it may be admitted that the speed of each motor will be in some inverse proportion to its size, and the number of poles should be chosen accordingly. Still exceptional demands may modify this rule. In view of this, it will be advantageous to provide each motor with a greater number of pole projections or coils, the number being preferably a multiple of two and three. By this means, by simply changing the connections of the coils, the motor may be adapted to any probable demands.

If the number of the poles in the motor is even, the action will be harmonious, and the proper result will be obtained; if this is not the case, the best plan to be followed is to make a motor with a double number of poles, and connect the same in the manner before indicated, so that half the number of poles result. Suppose, for instance, that the generator has twelve poles, and it would be desired to obtain a speed equal to $\frac{2}{3}$ of the speed of the generator. This would require a motor with seven pole projections or magnets, and such a motor could not be properly connected in the circuits unless fourteen armature coils would be provided, which would necessitate the employment of sliding contacts. To avoid this, the motor should be provided with fourteen magnets, and seven connected in each circuit, the magnets in each circuit alternating among themselves. The armature should have fourteen closed coils. The action of the motor will not be quite so perfect as in the case of an even number of poles, but the drawback will not be of a serious nature.

However, the disadvantages resulting from this unsymmetrical form will be reduced in the same proportion as the number of the poles is augmented.

If the generator has, say, n, and the motor n_1 poles, the speed of the motor will be equal to that of the generator multiplied by $\frac{n}{n_1}$.

The speed of the motor will generally be dependent on the number of the poles, but there may be exceptions to this rule. The speed may be modified by the phase of the currents in the circuits or by the character of the current impulses, or by intervals between each or between groups of impulses. Some of the possible cases are indicated in the diagrams Figs. 18, 19, 20, and 21, which are self explanatory. Fig. 18 represents the condition generally existing, and which secures the best result In such a case, if the typical form of motor illustrated in Fig. 14 is employed, one complete wave in each circuit will produce one revolution of the motor. In Fig. 19 the same result will be effected by one wave in each circuit; in Fig. 20 by two, and in Fig. 21 by four waves.

By such means any desired speed may be attained; that is at least, within the limits of practical demands. This systen possesses this advantage besides others, resulting from simplicity At full loads the motors show an efficiency fully equal to that of the continuous current motors. The transformers present an additional advantage in their capability of operating motors They are capable of similar modifications in construction, and will facilitate the introduction of motors and their adaptation to practical demands. Their efficiency should be higher than that of the present transformers, and I base my assertion on the following:—

In a transformer as constructed at present, we produce the currents in the secondary circuit by varying the strength of the primary or exciting currents. If we admit proportionality with respect to the iron core, the inductive effect exerted upon the secondary coil will be proportional to the numerical sum of the variations in the strength of the exciting current per unit of time; whence it follows that for a given variation any prolongation of the primary current will result in a proportional loss. In order to obtain rapid variations in the strength of the current, essential to efficient induction, a great number of undulations are required and employed. From this various disadvantages result. These are increased cost and diminished efficiency of the generator, more waste of energy in heating the cores and also diminished output of the transformer, since the core is not properly utilised, the reversals being too rapid. The inductive effect is also very small in certain phases, as will be apparent from a graphic representation, and there may be periods of inaction, if there are intervals between the succeeding current impulses or waves. In producing a shifting of the poles in the transformer, and thereby inducing currents, the induction is of the ideal character, being always maintained at its maximum action. It is also reasonable to assume that by a shifting of the poles less energy will be wasted than by reversals.

Notes.

CHEAP MATCHES.

"Indian Engineering" states that Japan is making rapid progress in the adoption of foreign machinery for cheaply manufacturing matches, as over 1,200,000 parcels of matches, valued at 300,000 dollars, were exported during the last year. It is believed that there is room for a similar industry in India.

PROPOSED FUEL TESTING STATION FOR LONDON.

In another part of the present issue will be found an important letter from Mr. Bryan Donkin, jun., on the above subject, in which he calls the attention of the coal producing and coal consuming public to the advantages which would follow the establishment of a systematically organised fuel testing station. Considering the vast quantity of coal yearly produced and consumed in England, it is surprising that this subject has never been brought before the public, especially as such stations have been in existence on the Continent for some time, and we hope that the scheme which our correspondent advocates will meet with the support of all those interested in the matter.

RECLAMATION OF LAND.

Our contemporary, *Indian Engineering*, states that an interesting work is about to be commenced in Northern Egypt. It is proposed to reclaim from the sea an area of land extending over 31,000 acres, and for this purpose works and steam pumps have already been erected at Abou-Kir.

BOILER EXPLOSIONS.

The Marine Department of the Board of Trade have issued their report on the working of the Boiler Explosions Act of 1882, for the year ended 30th June, 1887. During that period there were thirty-seven boiler explosions, causing twenty-four deaths, both figures being a little under the average of the years during which the Act has been in operation. In addition to the twenty-four persons killed by boiler explosions in 1886-87, forty-four were injured.

AGRICULTURAL MACHINERY IN ITALY.

The British Consul-General at Florence states that the small farmers of this district are opposed to innovations, and that improved ploughs, sowing and reaping machines, are but little known in the province. The nature of the ground also makes the use of machines difficult. Chaff cutters, however, have been generally adopted, owing to the increase in the number of stall fed animals. Thrashing machines, which are usually purchased by the landowners, are largely in use, and in the mountains which are difficult of access for steam engines, hand thrashing machines are used. All portable engines and thrashing machines supplied to the district should be fitted with efficient brakes.

BRITISH TEXTILES IN MEXICO.

In reporting on the trade of Vera Cruz, Consul Baker states that England has 63 per cent. of the trade in cotton goods, which form over 45 per cent. of her total imports at that port. France supplies 15 per cent., Germany 10 per cent., and the United States 10 per cent. The duties on cheap calicoes and prints were reduced last year, and an increase in the imports has consequently taken place. The Consul thinks that our proportion of the trade could be increased, as the French and Germans find a market for their goods not on account of greater cheapness, but because they consult the tastes of the consumers. Of the linen goods imported over 70 per cent. are British, but the trade is not very important. Of the imports of woollens, 50 per cent. are from France, and 26 per cent. from England, although British woollens are on the average cheaper. The reason given for this is that our rivals push their goods by means of clever salesmen in Mexico.

MANUFACTURE OF ALPHA-NAPHTHYLAMINE.

Dr. Otto N. Witt has recently described the methods used for successfully manufacturing this important base. It is essential that pure naphthalene be used, and a convenient charge consists of 250 kilo. mixed with 200 kilo. of nitric acid of 40° Bé., 200 kilo. of sulphuric acid, and 600 kilo. of the acid used in a former nitration. The operation is performed in cast iron cylinders, fitted with a cooling jacket to prevent the temperature from rising above 50°C. After twelve hours, the contents are transferred to leaden vats to cool, the waste acid run off, and the product washed with water until it is no longer acid. The reduction is effected in plant similar to that used for preparing aniline from nitrobenzene, iron borings and hydrochloric acid being the reducing agent employed. The temperature in this operation should not exceed 50°C. After about seven hours the reduction is complete, and milk of lime is added to the mixture. It is next distilled in a current of superheated steam, and the black oil is subsequently rectified in wrought iron stills. Naphthylamine prepared in this way is a colourless oil, solidifying to nearly white crystalline cakes, containing no β-naphthylamine, but small quantities of another base which is probably paranaphthylene-diamine. α-naphthylamine has been used for some time in the manufacture of "martius" or Manchester yellow, which is a salt of dinitro-(α)-naphthol, and is obtained from α-naphthylamine by the action of nitric acid. The sulphonate of this salt is obtained by the Schöllkopf Aniline and Chemical Company from α-naphthol-disulphonic acid by the action of nitric acid, and is known under the name of brilliant yellow. α-naphthol sulphonates are also used for the preparation of Tropœolin 0000 and scarlet G, which are azo colours obtained from them by means of the diazo compounds of aniline. When toluidine is substituted for the aniline, cochineal scarlet 2R is produced, and with xylidine the dyes formed are called azococcin 2R and cochineal scarlet 4R. Naphthylamine is also used for other dyes which are not at present the subject of any patent, and the demand for it is gradually increasing. It forms with sulphanilic acid and nitrous acid a red colouration which affords a very delicate test for minute quantities of nitrites.

Patent Record.

Compiled from "The Official Journal of the Patent Office," by W. E. Heys, *70, Market-street, Manchester.*

APPLICATIONS FOR PATENTS.

(The names in italics within parentheses are those of Communicators of Inventions.)

ENGINEERING.

25th May, 1888.

7654. Bohler, F. ..... Rail raiser.
7659. Ellis & Wilkinson ... Ejector mechanism of small arms.
7663. Smith, F. ..... Wire drawing.
7667. Finch, B. ..... Liquid fuel furnace.
7670. Harrison, J. ..... Sawing stone.
7672. Ormerod & Galloway Shedding motion of looms.
7686. Lake, H. H. ..... Manufacture of nails (*Cavalli*).
7692. Falkenstine & Varley Manufacture of screws, screw rivets, bolts, terminals, and other fittings used in connection with electrical appliances.
7698. Janiot, Madame ..... Gas engines.

26th May, 1888.

7704. Fawcett, F. B. ..... Manufacture of carpets.
7709. Thompson, W. P. ..... Ribbed tubes for boilers (*Serve*).
7710. Shackleton, R. ..... Additionally heating steam generators and feed water heaters by the application of hot air.
7711. Stott, A. H. ..... Mechanical stokers for marine boilers.
7716. Thompson, T. ..... Feed mechanism for cutting out and piercing tools.
7718. Watson, T. ..... Machinery for moulding dough.
7719. Mosley, T. ..... Apparatus for raking and loading hay.
7721. Brook, T. ..... Self lubricating revolving shafts.
7724. Chapman, G. ..... Propelling vessels.
7725. Igel, H. ..... Hosiery machines.
7729. Thomas, P. ..... Raising the temperature of the feed water supplied to the steam generator.
7733. Watson, R. F. ..... Yarn stretching and dyeing machine.
7734. Pass, E. de ..... Combing machines (*Imbs*).
7742. Brooke, R. G. ..... Injectors.
7752. Davis, S. ..... Car trucks.
7755. Kinipple, R. W. ..... Caissons and bridges to bridge across dock entrances.
7758. Baihe, C. R. ..... Waggon weighing apparatus.
7759. Barnaby, Sir N. ..... Battle ships.

28th May, 1888.

7764. Robinson, H. ..... Quick speed expansive fluid engines.
7766. Jackson, A. ..... Flue tubes of high pressure boilers.
7767. Fielding, J. ..... Pumping engines.
7769. Needham, W., & others. Manufacture of hollow fire bars.
7770. Bean, E. J. ..... Ships' steering gear.
7773. Gubbins, R. R. ..... Manufacturing wrought iron.
7785. Lock, C. ..... Couplings for railway vehicles.
7786. Werner, R. ..... Propulsion of boats.
7787. Boult, A. J. ..... Grain sorting machines (*Reitter*).
7790. Tate, G. ..... Propulsion of ships.
7791. Nordenfelt, T. ..... Automatic guns.
7794. Braun, J. ..... Lawn mowers.
7799. White, R. A. ..... Appliances for effecting the change of gauge of railway vehicles.

29th May, 1888.

7804. Gedge, W. E. ..... Propelling cars by compressed air (*The Auto-pneumatic Car Motor Co.*).
7808. Cocker, B. F. ..... Bearings for axles.
7813. Bullock & Bullock ... Extractor mechanism for drop-down small arms.
7822. Wilke & Schott ..... Manufacture of cut pile fabrics.
7823. Bonehill, C. G. ..... Breech-loading small arms.
7835. Rongier, H. ..... Weldless chains.
7836. Schuckert, S. ..... Machine for producing spherical, para boloidal, hyperboloidal, and ellipsoidal surfaces.
7837. Rae, R. J. ..... Ships' windlasses.
7845. Boult, A. J. ..... Saw mills (*Gowen*).
7859. Brook, E. ..... Arrangement of card cylinders in looms.
7861. Baker & Huyck ..... Concentric piston steam engines.
7868. Newton, H. E. ..... Delivery mechanism for web printing machines (*R. Hoe and Co.*).
7869. Lake, H. H. ..... Web printing machines (*Fowler and Henkle*).
7873. Lake, H. H. ..... Apparatus for drilling pipes containing fluids under pressure (*Roelants*).
7875. Joy, D. ..... Ordnance.
7877. Yarrow & Hilditch ... Fire engines.
7879. Whitehead, R. ..... Launching torpedoes.

30th May, 1888.

7886. Burke, J. M. ..... Securing railway rails to sleepers.
7893. Schnell, J. F. ..... Gas engines.
7895. Whitwam & Taylor ... Self acting mules.
7896. Michaelis, E., & others Gig mills.
7903. Sturgess & Towlson... Rotary engines and pumps.
7906. Pitt, H. H. ..... Pressed glass machine.
7908. Needham, N., & others.. Locking miners' safety lamps.
7912. Wentscher, E. ..... Type setting machine.
7918. Cary, F. ..... Pocket type writer.
7919. Quick, G. ..... Breech-loading ordnance.
7927. Stubbs, W. T. ..... Gas engines.
7928. Wootton & Clifton ... Manufacture of lace.
7934. Southall, J. ..... Gas engines.
7935. Tyler, E. H. ..... Submarine vessels.

31st May, 1888.

7941. Shalders & Thorman. Electromotive fountains and engines.
7945. Fairclough, G. ..... Lubricator.
7949. Higginson, A. ..... Pulleys and blocks.
7952. Rogers, J. E. ..... Frames for working pumps.
7953. White & Hardy ..... Condensing "exhaust steam" and supplying water to steam boilers.
7964. Thomson, W. ..... Axles of tram cars.
7965. Barnes, T. ..... Looms.
7967. Drage, J., & others..... Railway switches.
7969. Johnson, F. ..... Rotary knitting machines.
7970. Halot, E., & others ... Kneading or mixing machines.
7973. Bentall, F. W. ..... Lawn mowers.
7978. Bowen, T. ..... Engine pistons.
7982. Armstrong, J. W. ..... Fish joints for railways.
7983. Kortenbach & Rauh ... Machinery employed in the manufacture of umbrella ribs.
7991. Endicott & Abbey..... Starting gear for vehicles.
7995. Lake, H. H. ..... Converting iron into steel (*Hardmeyer, Hatch, & Jackson*).

ELECTRICITY.

25th May, 1888.

7655. Crompton, R. E. B..... Underground conductors of electricity.
7679. Sowerby & Chubb ..... Electric lamps.
7696. Coad, T. ..... Incandescent electric safety lamps.

26th May, 1888.

7720. Boardman, H. ..... Electric tell tales for checking watchmen.
7748. Hoppe & Hoppe ..... Electric motor for clocks, watches, and other apparatus.
7750. Dulait, J. ..... Electric arc lamps.

28th May, 1888.

7761. Burdon, C. B. ..... Applying electricity to a general system of traction.

29th May, 1888.

7805. Allison, H. J. ..... Distribution of electric currents (*Fritts*).
7826. Cox, H. B. ..... Galvanic generators.
7848. Thompson, W. P. ..... Indicators for alternating electric currents (*Westinghouse*).
7849. Thompson, W. P. ..... Detecting and locating faults in alternate electric circuits (*Westinghouse*).
7850. Thompson, W. P. ..... Alternate current electric distribution (*Westinghouse*).
7851. Thompson, W. P. ..... Switches for electric circuits (*Westinghouse*).
7852. Thompson, W. P. ..... Central station apparatus for system of electric distribution by alternate currents (*Westinghouse*).
7853. Thompson, W. P. ..... Storage batteries (*Gibson*).
7876. Willcox, B. ..... Electric batteries (*Abakanowicz and d'Arsonval*).

30th May, 1888.

7910. Schmidt, F. T. ..... Holders for incandescent lamps.
7916. O'Brien, T. ..... Transmitting written characters, and indicating and recording the indications of registering instruments by electricity.
7924. Boult, A. J. ..... Electric apparatus for firing mines (*Manet & Manet*).

31st May, 1888.

7977. Morris & Salom..... Filling secondary battery plates.

CHEMISTRY.

25th May, 1888.

7685. Forster, W. G. ..... Aluminium.
7687. Pitt, S. ..... Paint colours from nitrosophenols and their sulphonic acids (*Cassella & Co.*).

26th May, 1888.

7708. Goggs & Irvine ..... Metallic paints.
7746. Hardingham, G. G. M.. Manufacture of soap (*Magrini*).
7754. Tricket & Noad ..... Soda crystals and chlorides and oxides of various metals.

28th May, 1888.

7768. Spencer & Lord..... Apparatus for forcing and drawing chemical liquids.

29th May, 1888.

7830. Taylor, J. ..... Manufacture of soaps.
7867. Crookes, W. ..... Treatment of auriferous ores.

30th May, 1888.

7900. Bennett, J. E. ..... Treatment of metallic chlorides for extraction of metals therefrom.

31st May, 1888.

7997. Lake, H. H. ..... Colouring matters (*Oehler*).

MISCELLANEOUS.

25th May, 1888.

7656. Tattersall, A. A. ..... Increasing the draught in fire places.
7658. Birch & Baker ..... Door fastenings.
7661. Lee, C. ..... Gas burners.
7662. Lee, C. ..... Barometers.
7664. Fearon, H. S. ..... Fire proof flooring.
7671. Ormerod, B., and others Shuttle guards for looms.
7674. Lane, H. ..... Appliances for measuring air, gas, and other fluids.
7675. Gomm, F. R. ..... Ammunition.
7676. Moore, W. ..... Oil lamp.
7677. Wacks, W. ..... Utilisation of small coal or pit slack.
7682. Ashworth, J. A. ..... Chairs.
7683. Clarke & Williams... Systems of banding for spinning or twisting frames.
7684. Edwards, E. ..... Apparatus for damping and affixing postage stamps to letters (*Schneider & Schopf*).
7688. Nordenfelt, T. ..... Time fuses.
7689. Greatbach & Crake ... Igniting the fuses of blasting charges.
7690. Pitt, W. ..... Grab buckets.
7691. Chandler, S., & others. Washing and scrubbing gas.
7693. Kinslow, C. J. E. ..... Drain trap.
7695. Coad, T. ..... Lens for intensifying light.

26th May, 1888.

7703. Warrington, H. J..... Igniting fuses for blasting purposes.
7705. Bruce, A. ..... Three-way cocks.
7707. Thompson, W. P. ..... Aerating or storing natural mineral waters and other liquids (*Bravais*).
7713. Baker, F. R. ..... Oil lamps.
7715. Baker, F. R. ..... Extension lamps.
7723. Thurman, W. ..... Threading screws.
7726. Stead & Lancaster ... Purifying and softening water.
7727. Hawks, N. S. ..... Metallic packing for piston rods and valve spindles.
7728. Harrison, A. W. ..... Fire bars for circular grates.
7731. Forster, J. R. ..... Extracting corks from bottles.
7735. Moore, F. ..... Mordanting, dyeing, and washing wool and other materials.
7739. Jennings & Badère ... Stoppering bottles.
7740. Spong, C. W. ..... Supplementary door fastener for railway carriages.
7741. Tabrar & Dingwall ... Hermetically sealing bottles.
7744. Foster, C. F. ..... Stoppers for bottles.
7747. Snelus, G. J., & others... Cement.
7753. Adamson, T. A. ..... Cooling the bearings of machinery.
7756. Heartfield, H. ..... Stoppering bottles.
7757. Bell, F. ..... Bicycles.

28th May, 1888.

7763. Innes, T. ..... Printing blocks and type.
7765. Lehmann, A. J. ..... Drawing corks.
7776. Lotz, W. F. ..... Combined presser foot and tension regulator for sewing and embroidering machines (*von Pittler*).
7777. Scott, G. L. ..... Oil lamps.
7781. Smith, J. C. F. ..... Manufacture of cement.
7792. Ford, A. H. ..... Sliding doors.
7796. Bohringer, C. ..... Dyeing, washing, and drying fibrous or textile materials.
7798. Belmor, G. E. ..... Treatment of bituminous rock to adapt the same for paving.

29th May, 1888.

7800. Stuart, C. ..... Spanners and pipe wrenches.
7802. Smith, C. H. ..... Subjecting printed fabrics to the action of steam.
7806. Rae, J. ..... Forcing beer or other liquids.
7807. Gregory, G. F. ..... Oil tank (*Hutchins*).
7810. Miller, S. ..... Fire grates.
7811. Orr & Brown ..... Glazing.
7812. Cary, R. E. ..... Cycles.
7814. Turner, W. H. ..... Placing ware in enamelling kilns.
7815. Champion, J. K. ..... Lock bricks.
7819. Woodville, G. ..... Knives for cutting hay.
7820. Shelley, T. R. ..... Glazing.
7821. Rose & Daltry ..... Fire hose couplings.
7824. Yeadon & Sutcliffe... Healds employed in looms.
7846. Alexander, C. J. ..... Dyeing wool tops (*Alexander*).
7857. Day, C. A. ..... Jacks (*Warren*).
7858. Bommer, L. ..... Spring hinges.
7862. Parcelle, A. L. ..... Clocks.
7864. Day, S. P. ..... Self closing valve boss.
7865. Sutcliffe, M. ..... Stoppering bottles.
7866. Savage, F. ..... Extinguishing lamps.
7870. Klein, N. ..... Registering apparatus.
7872. Chapman, F. M. ..... Taps.
7878. Hobson, G. A. ..... Metal floorings or roofings.

30th May, 1888.

7883. Barry, J. H. ..... Purification of sewage.
7884. Trotter, A. P. ..... Transmitting the indications of thermometers.
7887. Grisenthwaite, J. ..... Combined swivel rowlock and fixed pin for feather oars and pin oars.
7889. Waterhouse, J. ..... Drain traps.
7890. Scotson & Willis ..... Anti-corrosive enamel for propeller blades.
7897. Homan, E. J. ..... Stencilling apparatus.
7899. Day, St. J. V. ..... Drying yarns and cloth (*Swan*).
7905. Dougall & Harries ... Artificial stone.
7909. Parkinson, J. ..... Parallel vice.
7913. Henderson & Wood ... Fastener for beltings.
7914. Löffler, H. L. ..... Locks.
7915. Fleiner, A., & others... Portland cement.
7917. Gritton & Whitherington ..... Removal of dust and sludge.
7920. Price, W. H. ..... Revolving lamps.
7925. Holloway & Holloway Block floors.

Digitized by Google

7929. Garton & Barkley ... Black varnish or enamel.
7936. Christophe, L. ..... Making roads.

31st May, 1888.

7943. Miller, A. T. ..... Arrangement of ships' yards, masts, rigging, and sails.
7946. Rowley, J. W..... Withdrawing corks from bottles.
7947. Jagger, B. ..... Purification of sewage.
7948. Greenwood, H. ..... Shuttle guards of looms.
7950. Vaughan & St. Aubin. Locks.
7955. McGlashan, A. ..... Valve for engines used for raising and forcing fluids.
7956. Griffin, J. ..... Springs for vehicles.
7957. Tonge, J. B. ..... Preventing down draught in chimneys.
7959. Ballardie, D. ..... Lamps.
7971. Fletcher, W. ..... Cleaning tramway lines.
7976. Margetts, W. G..... Portland cement.
7979. Staeber, G. ..... Pedomotive carriage for common roads.
7980. Undén, G..... Canoes.
7981. Abel, C. D..... Sieving apparatus (*Stringer*).
7992. Sault, L. A. ..... Transport and preservation of ice.
7993. Faller, F..... Clocks.
7996. Schladetz, H. W..... Velocipedes.
7998. Holman, F..... Shades and reflectors for incandescent electric lamps.

COMPLETE SPECIFICATIONS ACCEPTED.

Persons interested in opposing the grant of the following patents may give notice of opposition at any time within two months after the dates given.

ENGINEERING.

2nd June, 1888.

5989. Pohl, O. E. ..... Steam engines.
6643. Brierley, J. H. ..... Looms.
7726. Deacon, R. W..... Centrifugal drying machines (*Maxwell*).
8164. Hickling, W. E. ..... Sewing machines.
8449. Wehrstedt, A. R. J.von Magazine fire arms.
8497. Hax, C. F..... Automatic sharpening of saws.
8629. Robertson, J. ..... Shaping metal rings.
9284. James, J. W. H. ..... Transverse sleepers.
9568. Jochumsen, N. C. F. ... Furnaces for melting iron (*Hansen*).
9780. Whiteman, W. T. ..... Weighing and weight printing machinery (*United States Machine and Inventions Co.*).
9819. Hornsby, J., & others.. Sheaf binding harvesting machines.
10072. Mason, S. ..... Stone breaking machines.
10176A. Hahn, E. J. ..... Carburetters for gas motors. (This Application having been originally included in No. 10176, dated 20th July, 1887, takes, under Patents Rule 23, that date.)
10285. Adams, J. ..... Anti-friction apparatus for land and road rollers.
10325. Anderson, W. ..... Loading apparatus for breech-loading guns.
10327. Platt, J. ..... Machines for printing designs in correct register on both sides of a fabric at one operation.
10387. Wailes, J. W. ..... Open hearth steel melting furnaces.
10431. Farmer, Sir J..... Machinery for printing textile fabrics.
10434. Heys, W. E. ..... Lubricators (*Verny*).
10450. Godsal, P. T. ..... Breech-loading fire arms.
10459. Donovan & Wigham ... Combined disc stop and reversing valve applicable to steam winches and similar structures.
10460. Griffin, S. ..... Double cylinder gas motor engines.
10476. Holdsworth, G..... Machine for moulding cylinders and pipes.
10482. Reynolds, O. ..... Hydraulic brakes for causing and measuring resistance on rotating shafts.
10501. Long, J..... Metal ships.
10503. Guhl, H. A. H..... Type writers.
10579. Trueman & New..... Platen printing machines.
10590. Murgatroyd, E..... Securing the bosses of split pulleys upon shafts.
10596. Petrie & Dowell ..... Valves of steam engines.
10691. Savill, A. S..... Feeding steam generators.
10871. Galloway, C. J. ..... Steam boilers.
11214. Jackson & Martin..... Lock stitch sewing machines.
12696. List, G. A., & others ... Petroleum engines.
12863. Körting, E..... Gas engines.
13954. Irish, W. E..... Electrical railways.
15880. Vogt, H. C. ..... Propelling ships by means of air propellers.
16044. Hopton, A..... Platform for cooling wheel tyres.
18018. Burckhardt & Weiss... Surface condensers for steam engines.
18031. Hignette, J. J. ..... Centrifugal grinding mill. (Received 8th March, 1888. Ante-dated 18th October, 1887, under International Convention.)
248. O'Brien, J. O. ..... Rock boring machines. (*Bornet*).
1208. Martins & Rocha. ..... Operating railway switches and signals.
4038. Alexander, A. E..... Polished sheet iron. (*Craig*).
4273. Boult, A. J. ..... Increasing the frictional contact between the wheels and rails in railways. (*Ries*).
5293. Martin, B. D. ..... Manufacture of chill rolls.
5310. Thompson, W. P..... Fluid pressure motors and speed regulating devices therefor (*Benham*).
5709. Mauser, P. ..... Cartridge expellers for breech-loading fire arms.
5720. Cowburn, T., & others.. Continuous brake apparatus.
5914. Lake, H. H. ..... Hydrocarbon engines (*Spiel*).
6058. Robinson, C. H. ..... Tube expanders.
6163-4. Daniels, F. H..... Reeling apparatus for rod rolling mills.
6181. Hollingworth, E..... Shedding and taking-up motions of looms (*Hutchins*).
6211. Witthöfftt, L. ..... Circular saws.
6249. Okes, J. C. R. ..... Pumps.
6286. Anderson, A. ..... Sewing machines (*Singer Manufacturing Co.*)
6306. South & Bursch ..... Couplings for railway cars.
6352. Yaryan, H. T..... Purification of water in steam boilers.
6443. Sutro, L. ..... Knitting machines.
6445. Granville, B. ..... Type writing machines.
6473. Thompson, W. P..... Screw vessels (*Sylven*).
6886. Bookwalter, J. W..... Malleable iron or steel (*Robert*).
7050. Lake, H. H. ..... Universal shaft couplings (*Robes and Haskell*). (This Application was originally numbered in error 18037, 1887.)

ELECTRICITY.

2nd June, 1888.

7865. George, F..... Dynamos.
9191. Scott, G. A..... Type printing telegraphs.
9843. Goolden & Evershed.. Compensating electric measuring instruments for temperature.
10606. Gerard, L. ..... Distribution, storage, and regulation of electric currents.
10748. Schanschieff, A..... Portable batteries for electric light.
12645. Sandwell, W. D..... Electrical batteries for driving tramway vehicles.
1406. Turton & Turton ..... Combined electric and mechanical clock alarum.
4524. Barber-Starkey, W. J. S. ..... Portable galvanic batteries.
6237. Millar, A..... Cells for electric batteries.
6416. Hoppe & Hoppe ..... Galvanic elements.
6481. Lake, H. H. ..... Electrical transmission of power (*Tesla*).
6502. Lake, H. H. ..... Generation and distribution of electric currents (*Tesla*).

CHEMISTRY.

2nd June, 1888.

9690. Leuchtenberger and Moiske..... Purification of saccharine solutions.
10260. Kolbe, C. ..... Salols.
3793. Johnson, J. Y..... Metallic alloys (*La Société Anonyme Le Ferro-Nickel*).
6460. Lake, H. H. ..... Aluminium (*Seymour*).
6428. Thompson, W. P..... Preventing the decomposition of organic substances (*Moro*).

MISCELLANEOUS.

2nd June, 1888.

8056. Fiechter, L. B. ..... Separating dust from air (*Hardenbergh*).
8148. Breden, A. ..... Automatically extinguishing lamps.
8761. Munro, S. C. ..... Locks.
9109. Ewart, W. D. ..... Driving chains.
9285. James, J. W. H. ..... Lock nuts for screw bolts.
9367. Gibault, A. C..... Stop cocks.
10305. Hutchinson, E. H..... Compressing sea salt.
10383. Ashberry, P. ..... Sheep shears.
10395. Macdonald, J. K. ..... Shuttles and shuttle carriers for sewing machines (*Singer Manufacturing Co.*).
10410. Gillman & Spencer ... Bottling liquids.
10468. Burt & Edmonds ..... Lamps.
10477. Bosshardt, F. ..... Grinding grain (*Ricci*).
10490. Marston, R..... Lamps.
10512. Stewart & Charlton.. Storing volatile liquids.
10513. Stewart & Charlton.. Storing and transporting volatile liquids.
10591. Robertshaw, J. ..... Dyeing, sizing, washing, and wringing hanks.
10628. Mackenzie & Moncur.. Radiators for heating purposes.

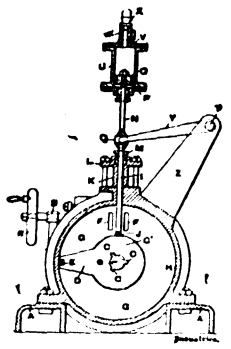
ABSTRACTS OF BRITISH PATENT SPECIFICATIONS.

Compiled from the Published Specifications by W. E. Heys, 70, *Market-street, Manchester.*

ENGINEERING.

Mules.—*E. Edwards, London.* (*R. Schneider, Biala, Austria.*)—In order to alter the direction of rotation of the spindles on an ordinary mule, the driving belts have to be altered or crossed. This invention is intended to obviate this disadvantage, and to effect the alteration by a special mechanism. The accompanying figure is a plan of the middle part of the spindle carriage and of the driving gear. The driving pulley G is mounted upon the hollow shaft F, which fits freely upon the solid shaft E. Motion is transmitted to the inner shaft by means of two bevelled toothed wheels, one being fixed upon the hollow shaft, and the other upon the solid shaft near one end; a third bevelled



wheel is arranged between them upon a separate shaft at right angles to the main shaft. By means of the movable couplings at the two ends of the hollow shaft, the two shafts may be connected and disconnected at will. If the two shafts are coupled, and the intermediate wheel thrown out of gear, the driving cord pulley will drive the spindle drums upon the ends of the inner shaft in the same direction. If the couplings are disconnected, and the three bevelled wheels thrown into gear, the driving pulley will continue to turn the outer shaft in the same direction, but that of the inner shaft and spindle drums will be reversed. The uncoupling and coupling is effected by means of sliding clutches. One claim is made.—No. 5837. April 21st, 1887. 8*d*.

Digitized by Google

Refining Iron.—*G. Lindenthal, Pittsburgh, Pennsylvania.*—In the ordinary Bessemer process the silicon and carbon are burned out first, and the sulphur and phosphorus leave the iron afterwards in the presence of basic material. According to this invention, after the desiliconisation and decarbonisation has been effected, a certain quantity of aluminium is added to the molten iron in order to increase the fluidity of the metal. The metal is then transferred to a rotary furnace, having an iron ore or basic lining. As the aluminium has reduced the melting point of the metal, the action of hardening takes a longer time, and thus a greater opportunity is allowed for dephosphorisation. The best proportion of aluminium for effecting this object, without at the same time introducing any other disadvantageous property, is about one-tenth per cent. The inventor makes three claims for the addition of aluminium for the purpose of delaying the hardening of the molten iron, in order to allow a longer time for dephosphorisation.—No. 4951. April 3rd, 1888. 6*d.*

Rotary Engine.—*T. T. Kemp, Bristol.*—The special features of this invention consist of a sliding abutment in the piston chamber, whose movements are effected by steam, and of a check valve for preventing the waste of steam during the withdrawal of the abutment. The arrangement of the rotating disc and other parts is shown in cross section in the figure. The disc C' and plate D are fixed to the shaft B by means of the keys C. The packing piece E insures a tight joint between the plate D, and the sides of the cylinder H. The steam ports are shown at F, and the sliding abutment at I. The piston rod N is connected to the piston O, which works in the cylinder U, and the lever Y works at one end in the box Q, and is fixed at the other to the shaft T, which works in bearings in the projection Z. In working the engine, steam is admitted through one of the ports F, and the piston is consequently driven round; when it reaches the sliding abutment I the steam is cut off, and a cam on a boss on the shaft outside the cylinder causes the lever Y to be raised by suitable

links and levers, and by the simultaneous admission of steam into the cylinder U. The abutment will thus be raised and the plate D will be allowed to continue its travel, the exhaust steam passing out at the other port. The steam enters the cylinder through a check valve, which is adapted to prevent a waste of steam during the time that the sliding abutment is temporarily raised to allow the piston to pass. This valve is operated by an eccentric on the main axis, so that the steam is cut off during the above mentioned part of the revolution of the disc. In the descent of the abutment, the steam under the piston in the cylinder U acts as an unbreakable spring; the check valve performs also another duty, viz., to make the engine act expansively. Six claims are made for this arrangement of disc, ports, and abutment, and for the combination of the parts for operating them; and for the use of the check valve for the purposes described.—No. 7654. May 26th, 1887. 1*s.* 1*d.*

Cap Spinning and Twisting Frames.—*L. Binns, Philadelphia.*—In order to prevent the driving bands of the whirl tubes prematurely losing their power and tightness, the inventor applies an automatic adjustment to them. An endless band connects and drives the whirl tubes or their whirls, and traverse bars on opposite sides of the frame are given a reverse alternate motion simultaneously with each other. The bobbins have a uniform motion up and down. The whirl tubes are accordingly constantly giving and receiving more length of band as is necessary, without stretching the band or straining the spindles. Two claims are made.—No. 3153. March 1st, 1888. 8*d.*

Valve Gear.—*J. M. MacCulloch, Garston, Lancashire.*—The link motion here described is operated by a single eccentric, and the slotting action of the block in the link is also much reduced. The curved slotted link is connected to the eccentric strap by means of two rods pivoted at each end; and another shorter rod connects the eccentric strap with a fixed point on the frame. The reversal of the engine can be effected by moving the link up or down, so as to make the block assume different positions in the slot. Two claims are made.—No. 8057. June 4th, 1887. 8*d.*

Stone Working Machines.—*F. Trier, London.*—The circular rotating cutters are placed on the slides of planing machines with tables which are driven by a crank action. When the length of stone to be dressed renders the direct action inconvenient, the table is driven by a crank in connection with a log and plank motion similar to that employed in printing machines. The tool holders can have the necessary skew imparted to them, and may be reversed as required by the alternating movement of the table. Another improvement relates to the method of cutting out internal angles; two cutters are mounted on separate converging slides, and their axes may be placed either in the same plane or in different planes. Seven claims are made.—No. 7036. May 13th, 1887. 8*d.*

Pneumatic Tram Locomotive.—*W. P. O'Neill, Longford, and F. O'Neill, Dalkey, near Dublin.*—The locomotive here described combines the characteristics of horse power tram engines, viz., that extra power shall be available for starting the engine and for ascending inclines. A petroleum motor actuates an air compressing pump, and the compressed air passes to a receiver and afterwards to a double acting motor cylinder. There is a vapour producer for moistening the air before entering the compresser, in order to reduce the loss of power owing to the rise of temperature of the compressed air. There is also a reducing valve between the compresser and the motor cylinders, by means of which the supply of air may be adjusted to requirements. Six claims are made for moistening the air and for the construction of the compresser and receiver.—No. 4813. March 29th, 1888. 11*d.*

Hydrocarbon Furnaces.—*C. R. Hoopes, Philadelphia.*—The oil supply pipe is led through a hot air chamber, which is provided with a blast nozzle close to the oil nozzle. A pressure blower forces air through a series of pipes in the furnace, in order to heat it before it issues through the blast nozzle. The highly heated air while in the hot air chamber surrounds the oil supply pipe, and thus imparts some of its heat to the oil. The vaporised oil, on mixing with the hot blast of air, burns completely, and no deposition is left in the tube, nor does any spray of oil fall unconsumed to the bottom of the furnace. Thirteen claims are made.—No. 3910. March 13th, 1888. 8*d.*

Slide Valves.—*A. Tolhurst & H. Skinner, Gravesend.*—The object of this invention is to provide improved means for relieving the back of the slide valves from the pressure of steam, and thus to reduce the wear of the bearing surfaces. Fig. 1 shows the application of this method to a single slide valve. The back of the slide valve A is faced as well as the front, and a plate C is held against the back, and is adjustably carried

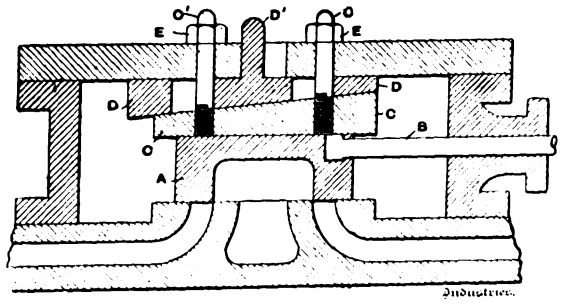


Fig. 1.

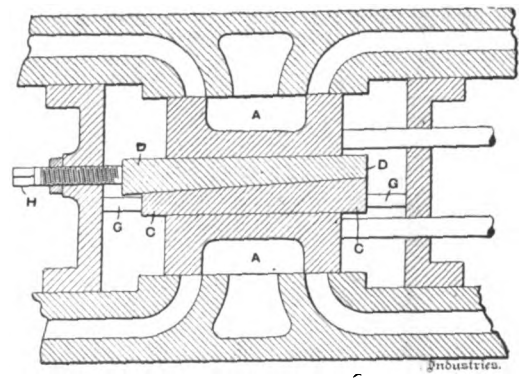
by the cover of the chest. The upper surface of C is somewhat inclined, and between it and the cover is interposed another wedge D, which can be moved endwise in order to shift the plate C towards or away from the valve. The plate has pins projecting from its upper side, and passing through slots in the wedge D, and through holes in the cover. A pin D' also projects



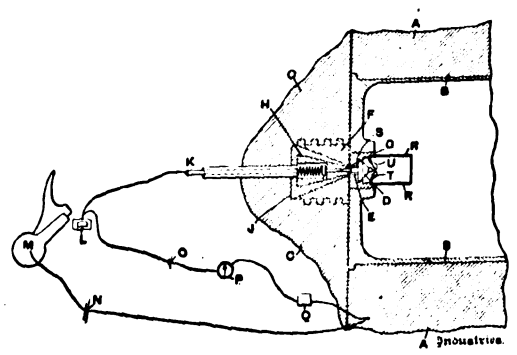


Fig. 2.

from the back of the wedge through a slot in the cover, and by means of this pin the wedge can be moved longitudinally. Fig. 2 illustrates the application of the same principle to a valve chest containing a pair of slide valves working back to back. Two wedge plates C and D are interposed between the two valves A. The plate D can be moved longitudinally by means of the screw H, and the other plate is prevented from similar motion by the stops G; but it can, however, be moved towards or away from the valve on which it bears. Four claims are made for the ways of carrying out this invention, described in the specification, by preventing the steam exerting its pressure on the back of the slide valve.—No. 8097. June 4th, 1887. 8*d.*

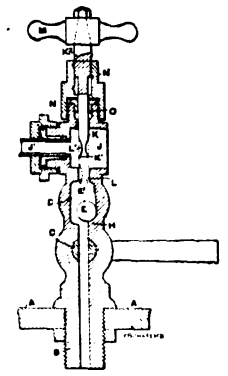
Plate Bending Machines.—*J. Barrow, Johnstone, Renfrew.*—It is sometimes necessary to construct the vertical plate bending machine in such a way that after a plate is bent to a complete circle the third driving roll may be lifted clear of the work, to allow of the removal of the plate. The object of the present invention is to obviate some of the disadvantages incident on the ordinary method of lifting the third driving roll. The journals of the roll are carried in blocks, which act as nuts, and screws are fitted into these nuts, to regulate the distance apart of the bending rolls. A rack gearing with a pinion is attached to the bottom block, and the top framing is arranged so as to allow the top block a free exit and entrance. The foundation plate is extended at the place where the lower block is fitted. With this arrangement, the two adjusting screws can be screwed out of the nuts after the plate has been bent to a complete circle, and the motion of the third roll can be continued by means of the rack and pinion until it is clear of any obstruction; the roll can then be either lifted clear of the work, or the work itself can be removed. The inventor claims: In vertical plate bending machines, arranging one of the rolls in bearings fitted in horizontal slides in the upper and lower parts of the framing, so that the roll or the work may be removed sufficiently far outwards for being lifted vertically upwards.—No. 13945. October 14th, 1887. 11*d.*

ELECTRICITY.

Firing Ordnance by Electricity.—*T. Nordenfelt, London.*—The accompanying figure shows a longitudinal section of the fuse and part of the gun and breech block, and also the arrangement of circuits in diagram. The cartridge case B carries a tube R containing the priming. T is a plug of vulcanite, and U is a loop of platinum wire, whose ends are connected to the tube R. The metallic button D is carried by the rear of the plug T, and is in contact with the loop of the wire U; the shoulder of

the button rests against the disc S at the base of the priming tube, being separated from it by a minutely thin layer of vulcanite, mica, or other insulating material; and its stem passes partially out at the rear of the priming tube, and is surrounded by an insulating collar. The priming is forced into the tube R under great pressure in order to insure its mechanical contact with the platinum wire, and the end of the priming is then soaked in varnish to render it secure and water tight. The steel plug F is screwed into the breech block, and is made hollow to contain a spring pin G, which is surrounded by the metal box H and the insulating material J. The insulated wire K is in electrical connection with the spring pin G. The insulated contact L enables the trigger M to close the circuit from the low resistance firing cell N through the gun. O is the indicator cell, P is a galvanometer in the indicating circuit, and Q is a switch which may or may not be used. The inventor makes six claims for the combination of the disc S, button D, and thin layer of insulating material; for the combination of the tube R, plug T, and button D; for the hard plug F and spring pin G, and metal box H, as described.—No. 8710. June 16th, 1887. 8*d.*

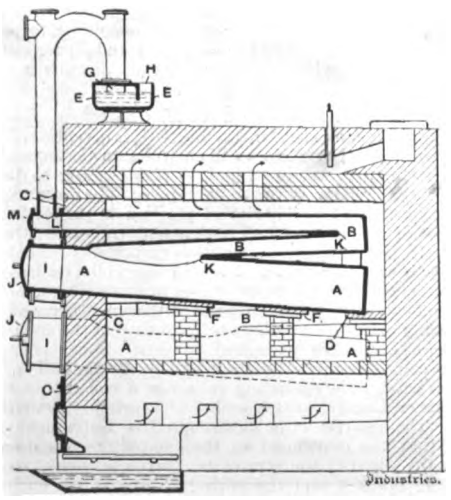
Regulating Dynamos.—*F. George, Uley, Gloucestershire.*—For the purpose of regulating dynamos, a shunt coil is wound upon the electromagnets, whose magnetisation may thus be diminished or increased according to the direction of the current in the shunt. By means of this current a secondary battery is introduced into parallel arc with the dynamo, and the current from it, being sent through the shunt coil in either direction according to the requirements of the case, serves to regulate the e.m.f. of the dynamo. A similar arrangement is applicable for maintaining a uniform e.m.f. between two or more dynamos coupled in parallel. In this case the secondary battery is omitted, and the dynamos act as regulators for each other, by being connected at the brushes, and by the connections being carried as shunt coils round the field magnets of each in such a manner that, should the e.m.f. of any exceed that of the others, the direction of the current would cause the magnetisation of its field magnets to be diminished, and that of the others to be increased. If the e.m.f. of any fell below that of the rest, the reverse action would take place. Three claims are made: (1) For the use of a coil or coils on the field magnets carrying a reversible current, increasing or diminishing the magnetisation according to the direction of the current; (2) for the use of accumulators coupled in parallel with the dynamo by means of such a coil; and (3) for coupling two or more dynamos in parallel by means of such a coil or coils.—No. 7553. May 25th, 1887. 4*d.*



Voltmeters.—*J. A. Fleming & C. H. Gimingham, London.*—The instruments, constructed according to this invention, depend upon the principle that when a coil encircles an electromagnetic pole, there will be a force brought into play tending to displace the movable coil relatively to the fixed pole. The force required to bring back the coil to its original position is proportional to the product of the strengths of the current traversing the two windings. A bar carries a coil at each end, and is mounted at its centre on a needle point. Each of the coils encircles the poles of the two electromagnetic helices in line with each other; and all the helices are joined in series with each other, and with the encircling coils, the windings being such that the ends of the electromagnetic helices presented to each other where the encircling coils surround them are of like denomination. The bar, which carries the encircling coils, has a coiled steel spring fixed to one end, and the other end of the spring is secured to a bracket. The electric circuit through the instrument is so arranged that the movement of the encircling coils does not interrupt the circuit; the circuit is, therefore, made to pass through the bracket and the spring to one of the encircling coils, then round the other encircling coils to the seating which receives the pivot, and round the helices. A scale and pointer are fixed on the instrument; the pointer is fixed to a part of the apparatus, by the motion of which the spring can be displaced from its normal position. Attached to the coils is another pointer, which points to zero when the instrument is adjusted. When a current traverses the instrument, the encircling coils move on their supporting pivot and compress the spring. To take the measurement, the first pointer is moved round until the second points to the zero mark; the first pointer then indicates the e.m.f. When the instrument is required for use as a watt meter, the encircling coils are wound with a fine wire, ending in one pair of terminals for attachment on either side of the lamp or other device, so that the coils are in a shunt from the line. The helices are wound with coarse wire, and like poles are encircled by the coils as before; this coarse wire is carried to the terminals on the instrument to which, while

Digitized by Google

testing, the line is attached; the windings of the helices are thus in series with the line. Five claims are made.—No. 10963. August 10th, 1887. 11*d*.

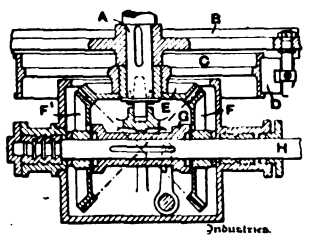


MISCELLANEOUS.

WATER GAUGES FOR STEAM BOILERS.—*S. Matthews, Sunderland.*—This invention relates to that class of water gauges in which a ball valve is used; the modifications here introduced will be understood by reference to the accompanying figure. A is the end plate of the boiler, and C is the ordinary gland cock for controlling the connection between the inside of the gauge with the boiler. The ball valve E works in the chamber D, to which access is gained from the outside by a screwed plug for the purposes of cleaning. The bottom of the chamber D is sloped towards the boiler, so that the normal position of E shall be at the lowest point at H. The gauge glass J¹ is fitted into the chamber J, and the area of the aperture L is governed by the position of the spindle K. The end K¹ is hollowed out to the radius of the ball valve, and its diameter for a short distance from that end is reduced and fluted. The outer end of the spindle is made of a somewhat larger diameter than the inner end, and the nut N, through which the spindle passes, is arranged

with a quick pitched thread, so that a half turn of the handle M gives a horizontal travel to the spindle accordingly. The nut N also screws the gland O upon its packing. This arrangement of the double nut, with threads of different pitch, allows the spindle to be removed without the nut and the glands being disturbed. Under ordinary conditions, the cock C is open, the valve E rests on its seat at the bottom of the chamber D, and the spindle is in the position shown in the figure. When it is necessary to blow through the apparatus for the purpose of cleaning the glass, the ball is forced into the position E¹, and the spindle is not only arranged with sufficient travel to hold the ball off its seat, but its fluted ends afford a passage for the steam and water past the spindle and through the port L. When a gauge glass bursts, the ball E is immediately forced by the steam into the position E, which effectually prevents the egress of steam and water from the boiler; the attendant having closed the cock C, the ball returns to its seat by gravitation, and a new glass can then be fitted. The inventor makes two claims for the combination of the inclined seating, the adjustable plug, the spindle K, and nut N, as described.—No. 3347. March 5th, 1888. 6*d*.

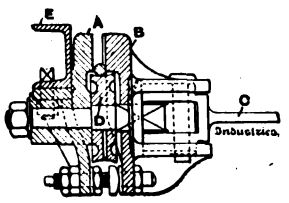
MANUFACTURE OF GAS.—*J. H. R. Dinsmore, Liverpool.*—The objects of this invention are to cause the heavier hydrocarbons to become more permanently suspended, and to arrest a great portion of the tar before it reaches the hydraulic main. For



these purposes the retorts and apparatus are arranged as shown in the accompanying figure. A is the main cast iron retort, and B is a duct through which the distilled gases pass, after their evolution in the retort. The retort door is shown at J; the seating consists of the front wall C and the pedestal D. In practice three retorts may be used, and their settings are such that they shall be protected from the destructive effect of the flames, and maintained at equal temperatures. This is done by shielding those parts nearest the fire by brick work, and by the slabs F. In order to allow of all the parts being cleaned, the retort and duct are so constructed that they may all be scraped from their mouths, and the parts K are formed as a feather edge. The ascension pipes lead to a hydraulic main E, whose dip pipes G are inserted into the liquor for a small depth only. The gas is thus allowed to pass freely out and into the main, and little back pressure is caused in the retort. The main is open at E² to the atmosphere, and any undue pressure is thus prevented within it. It is claimed for this arrangement of the retort and duct, and flues surrounding them, that a greater lighting power of the gas is obtained by the heavy hydrocarbons being more thoroughly utilised by their subsequent heating in the duct. Two claims are made for the retort and duct, and for the arrangement of the hydraulic main as described.—No. 1767. February 4th, 1887. 8*d*.

JACQUARD CARDS.—*W. Martin & W. T. Martin, Nottingham.*—In the process of selecting and punching patterns in jacquard cards, the inventors use a bed with a pair of perforated punch plates, which work up and down by means of eccentrics and connections from a revolving shaft. The punch plates are grooved so as to allow the cards to pass between them, and the cards are fed from a bottomless box by means of endless bands. These bands are studded the exact width of the cards, and they travel under the bottomless box and between the punch plates by means of an arrangement of rocking apparatus. Above the bed is a block, which is perforated horizontally for the selecting keys, and vertically for the punches; the block is also fitted with perforated slays, which together with the block carry the selecting keys and the punches. On each key is a spring, which returns the key to its proper position after being drawn back by the string in the ordinary way. When the bed containing the punch plates is at its lowest point, the bands travel the width of one card; but while the bed and plates ascend and lift the card to the punches, the bands do not move. The punches, being held in their proper position by the keys, perforate the card; immediately afterwards the bed and the plates descend, and the same motion which takes the blank card into the plates brings the punched card out of the plates, and propels it down a slope into another box. The arrangement of rocking apparatus above mentioned consists of a ratchet wheel and pawl, with a connection lever and spring worked by a cam on the eccentric shaft. By this invention, only one attendant is required to select the keys. Four claims are made.—No. 6389. May 2nd, 1887. 8*d*.

DUST COLLECTOR.—*C. R. Grundig, E. Löwe, & F. Zahn, Dresden.*—The apparatus is in the form of a spiral passage, through which the current of dusty air passes. There are a number of slotted tubes arranged along the outer sides of the passage for the purpose of catching and evacuating the suspended matter. The centrifugal force imparted to the air current in the curved passage causes the matter to be deposited on its outer sides, and the slotted tubes afford an escape for it. The dust is collected in bags as it falls from the apparatus. Four claims are made for the spiral channel and slotted tubes.—No. 4269. March 20th, 1888. 6*d*.



GERMAN PATENT ABSTRACTS.

REVERSING GEAR.—*C. Daevel, Kiel, and the firm Benz & Co., Mannheim.*—The operating shaft A is fitted with a fly wheel B, to which the brake strap D is connected. The brake drum C is firmly connected to the bevel wheel E, but C and E are free to

rotate on the shaft A. The bevel wheel E gears with two bevel wheels F and F¹, and either of them may be connected to the shaft H by the coupling G. The interposition of the brake drum C and the strap D avoids the shock when reversing the motion of H by engaging the coupling G with F or F¹.—No. 42819. September 1st, 1887.

CABLE TRAMWAYS.—*T. Otto, Schkeuditz.*—This invention relates to an improved apparatus for connecting the cars to the wire

rope. The rope is gripped between a vertical jaw A, fixed to the frame E of the car, and a movable jaw B. B is actuated by the lever C. Between the two jaws a roller D is arranged for supporting the wire rope.—No. 43000. January 25th, 1887.

UNITED STATES PATENT ABSTRACTS.

COLLECTING LINT.—*J. W. Shell, Evening Shade, Arkansas.*—The receiver for the lint rolls upon a track, and is provided with a foraminous door at one end and sliding doors at the end adjacent to the gin. After the receiver has been filled from the gin flue it is rolled back to the press. The foraminous door is then removed, and the sliding door is drawn through the receiver, compressing the lint in its passage. Two claims are made.—No. 382775, dated 15th May, 1888.

LOOMS.—*Z. T. McKinney, Piedmont, South Carolina.*—This invention relates to the shuttle relief mechanism. One of the swords of the lay carries a bell crank lever which is connected at one end to one of the lay pitmen, and carries an anti-friction roller at the other end. This roller bears upon an arm connected to a rock shaft, which carries a finger, and a spring in proximity to the shaft normally presses the finger against the guard. Just before the forward movement of the lay the levers release the pressure of the finger from the shuttle binder. Three claims are made.—No. 382995, dated 15th May, 1888.

CONSTRUCTION OF IRON ROOFS.—*H. C. Hodges, Detroit, Michigan.*—The inventor here introduces an improved method of joining together the roof sheet, the purlin, and the rafter. Two blocks of metal D and E are employed; the upper surface of D is rounded to conform with a corrugation in the roof sheet C and its lower surface grasps the purlin B. The block E is grooved

FIG. 1

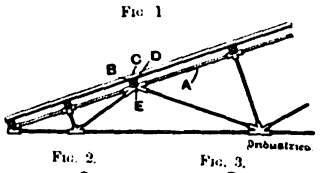


FIG. 2.

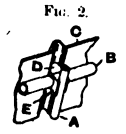

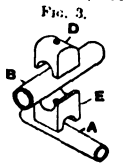

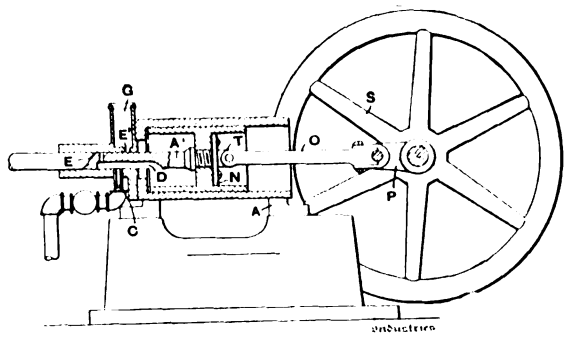

FIG. 3.

on the upper and lower sides with two channels at right angles to each other, to receive the purlin B and to rest on the rafter A respectively. Holes are drilled through the blocks in order to allow a bolt to pass through, for the purpose of holding the parts together. Four claims are made for the use of these blocks.—No. 381137, dated 17th April, 1888.

GAS ENGINE.—*G. W. Stewart, New York.*—This invention relates to a method of introducing the gas into the cylinder of the engine, and the accompanying figure illustrates the mechanism employed for that purpose. The piston has an extension A¹, which passes through the hinder end of the cylinder. In this circular rod is a groove D, which allows the gas to find access to the cylinder from the gas supply pipe C. There is also a narrow

port E in the rod A¹, and a port E¹ in the surface on which the rod bears. When these two ports register with each other the flame in G is communicated to the charge in the cylinder, and the explosion takes place. The air supply and the exhaust mechanism are not shown in the drawing. Four claims are made for the extension A¹, and for the grooves in it, as described.—No. 381488, dated 17th April, 1888.

COTTON BATTING.—*E. Walker & D. Williams, Cohoes, New York.*—In this method of making cotton batting the fleeces from several carding engines are obliquely deposited upon an apron travelling at right angles to the front of the engines. A bat is thus formed of layers whose fibres lie obliquely to the direction of the length of the web, and the fibres of each layer lie across the fibres of the layer beneath. The bat is afterwards folded in a direction parallel with the edges, the best grade of stock being used for the outside layer. Three claims are made.—No. 382916, dated 15th May, 1888.

ETCHING GLASS.—*E. Nienstadt, New York.*—This process for etching glass and porcelain consists in first stamping the design upon the surface with a sticky compound of resin and fatty oil, and afterwards spreading the stamped portion of the surface with pulverised hydrofluorate of ammonia, which contains a portion of free hydrofluoric acid. The material when in this state is subjected to the action of slightly warmed moist air. The advantage of this process is that the action of etching is delayed until the preparation of the surface is completed, as the etching materials cannot commence their action until the warm moist air has affected them. One claim is made.—No. 382318, dated 8th May, 1888.

The full specifications of the British and United States patents, and the Official Journals of the German Patent Office, from which the above abstracts have been compiled, and the Official Journal of the United States Patent Office, may be seen by subscribers and clients at the Reading Room, Manchester Office of INDUSTRIES, *where also Patent Indexes from* A.D. 1617 *may be consulted. Copies of the British specifications may be obtained on application to* H. READER LACK, ESQ., *Comptroller-General, Patent Office, Southampton Buildings, London, W.C. The published price must be remitted, together with a sum sufficient to cover postage, which may be reckoned at ½d. for every* 10*d. or fraction of* 10*d. Remittances exceeding one shilling must be made by Post Office Order.*

GLASGOW INTERNATIONAL EXHIBITION.

English Steel Exhibits.—The English steel manufacturers are fairly well represented, though several eminent firms, such as Sir Joseph Whitworth & Co., Messrs. Firth, the Butterley Company, and others, which have been prominent exhibitors in recent years at other places, are conspicuous by their absence. All the larger steel exhibits are situated in the main avenue of the machinery section, and adjacent to the trophies of the leading Scotch firms. Taking them in the order in which they are approached by the visitor entering the section from the main building, there is first the splendid exhibit of the Hadfield Steel Foundry Company, Sheffield. This large and varied display, comprising hundreds of different articles, weighing in all some 50 tons, seems intended to illustrate almost every possible purpose to which cast steel can be applied. An idea of the general character of the exhibit will be best conveyed by a rough classification of the different specimens according to their intended uses. The supply of castings for colliery, mining, and contractor's plant was, we believe, the earliest branch of Messrs. Hadfield's business, and in this department are shown various descriptions of wheels and axles—several of them being patented specialties—pedestals, rollers, cage guides, pulleys, crossings, stamps, cams, levers, and, in short, everything required in connection with mining which can be cast in steel. The magnitude of this branch will be realised when it is mentioned that considerably over 2,000,000 Hadfield cast steel wheels and axles are now in daily use in different parts of the world. A pair of trolley wheels mounted on an axle, which fell down a colliery shaft 1770ft. deep, without suffering any further injury than bending of the axle, and a small wheel with the arms forged out into a knife, fork, &c., as well as other specimens of interest, testify to the strength and toughness of the material used. Hydraulic engineering is represented by a group of eight cast steel cylinders, which are, perhaps, the most striking feature of the exhibit. They range in length from 6ft. to 20ft., with internal diameters of from 6in. to 36in.; and the soundness of the metal is proved by the turned and polished portions of their exterior surfaces. The requirements of railway and tramway engineers have been well considered, and locomotive wheel centres up to 8ft. diam., cast steel roof stay bars, horn blocks, axle boxes, motion plates, crossheads, and the well known "Hecla" patent railway and tramway wheels are shown in a great variety of forms. Some "Hecla" wheels, cast entirely in one piece without any rolling or forging, have proved when tested under express locomotives, practically equal in durability to the best rolled steel tyres, while for tramway purposes these wheels are favourably known all over the world. We may here mention that since the opening of the Exhibition Messrs. Hadfield have been successful in obtaining large orders for general locomotive castings from Glasgow builders in face of severe home and foreign competition. For rolling mills and general gearing purposes are shown a number of pinions, spindles, anvils, &c., and every description of spur, bevel, mitre, segment, and worm wheels, with both straight and helical teeth, and either machine moulded or made from full patterns. Marine engineers and shipbuilders' castings are not so largely represented; but there are several good examples of crank, lever, crosshead, and propeller blade castings, as well as a number of requisites for dredgers, including Hadfield's patent cast steel buckets, bucket backs, lips, links, tumblers, &c. War material forms another specialty of this firm, and they give some interesting exhibits of their patent cast steel projectiles, shells, and machine gun carriages. A cast projectile for a 9·2in breech-loading gun, which penetrated two "Cammell" wrought iron armour plates, with a combined thickness of 24¾in. and 2ft. of wood backing, and a 6in. projectile which has passed through an 8in. wrought iron plate, both remaining practically uninjured, are especially worthy of notice. A forged 6in. steel projectile is also shown, which penetrated a 9in. compound "Cammell" plate. This is claimed to be the first English projectile that has successfully pierced the compound armour plates. Our space will only permit a passing allusion to the numerous and instructive collection of test bars of both unhammered and forged cast steel, giving tensile strengths ranging from 26 tons to 125 tons per square inch, with corresponding elongations from 40 per cent. to 1 per cent. With a brief reference to the patent manganese steel specimens contained in the cases on the south side of the stand, we must close our notice of what is undoubtedly the finest display of steel castings in the present Exhibition. Full abstracts of the two able papers entitled "Manganese in its Application to Metallurgy," and "Some Novel Properties of Iron and Manganese," were published on page 250 of our present volume. Those papers were read by Mr. Robert A. Hadfield before the Institution of Civil Engineers, the samples alluded to above being used to explain and illustrate his remarks. One of the many remarkable properties of this metal is its small susceptibility to magnetisation, and some of the specimens are arranged to show the diminution of the magnetic qualities as the percentage of manganese increases. Professor W. F. Barrett has stated that its peculiarity in this respect indicates a large employment of manganese steel for the construction of dynamos and other electric appliances.

The ponderous exhibit of Messrs. Charles Cammell and Co., Limited, next invites inspection. The gigantic three-throw crank shaft, resting upon the top of the specimen armour plates, at once strikes the eye as being among the most imposing objects in the machinery section. The effect it produces is somewhat lessened by the discovery that it is only a well finished wooden model of a shaft, weighing nearly 60 tons, made for the steamship "Aurania," of the Cunard Line. At the front of the stand lies a splendid forging of about 24 tons weight, intended for the core of a 68-ton gun. It is turned and polished on the exterior, the interior being rough bored, ready for finishing; and is in every respect a creditable specimen of ordnance manufacture. Smaller gun pieces are disposed behind; the entire assortment representing forgings for guns from 6in. B.L.R. up to 13·5in. B.L.R. In the centre of the stand is placed a large gun trunnion ring, with a glass case containing a neat arrangement of files, tool steel bars, &c., fitted into the end facing the spectator. Armour plates, as may be expected from the well known reputation of the firm, form a prominent feature of the exhibit. The great superiority of compound armour over solid iron armour is demonstrated by two heavy tested plates which are exhibited. In the one case the projectile, though broken, has penetrated the iron plate, while the steel faced plate, under precisely similar conditions of testing, has sustained comparatively little damage. A full sized model of the 10½in. compound plate tested at Portsmouth on the 24th March last, is also shown. This plate was struck by three Holtzer forged steel projectiles and two Palliser chilled cast iron projectiles, fired at the close range of 10 yards, but all completely failed to penetrate it; and the makers claim that it is the finest piece of compound armour ever made. The methods of securing the armour plates to the backing are illustrated by sections cut through actual plates and bolts. A variety of steel projectiles, forged shells, various marine and railway castings, sections of rails and fish plates, and assortments of bearing, volute, conical, and spiral springs, tastefully grouped among the larger objects, give completeness to this effective exhibit.

Messrs. John Brown & Co., Limited, Atlas Works, Sheffield, occupy a larger floor space than any other steel firm. They have a frontage of 60ft. in length on the south side of the main avenue, and show a number of large and interesting examples of their well known manufactures. This firm has long been famous for armour plates, and one of the most instructive sections of the exhibit consists of five plates of different periods, showing the advances made in this branch of defensive warfare. The first plate (No. 1) shows the early type of solid iron armour, and the impression made on it by the now obsolete spherical cast iron shot. Another iron plate (No. 2) demonstrates the superior penetrative power of the pointed chilled cast iron Palliser projectiles which superseded the spherical shot. Plate No. 3 is machined off an iron plate 22in. thick, the heaviest armour ever actually used; and plates No. 4 and No. 5 are specimens of the compound or steel faced armour plates presently manufactured by the firm under the patents of Mr. J. D. Ellis, now one of the leading partners. The severe tests which these compound plates have successfully withstood can leave no possible doubt as to their superiority over the older description of armour. The great feature of this exhibit, however, is an immense Siemens steel propeller shaft forging, 60ft. long and 19in. in diameter, with a 23in. collar and a 42in. coupling flange. This truly magnificent piece of work, which takes up the full length of the front of the stand, has been entirely executed under the large hydraulic forging press recently erected by Messrs. Brown & Co. This is probably the largest forging appliance in existence, and enables the firm to produce with ease the very heaviest classes of marine and ordnance forgings. The Atlas works has also an exceptionally complete equipment of machine tools for dealing with heavy masses of steel, and but for want of time the propeller shaft would have been shown bored through from end to end. Another prominent object occupying the west end of the stand is a huge marine boiler front plate, with four Purves patent ribbed steel flues attached in position. The merits of these flues, of which Messrs. Brown & Co. are the sole makers, will be more fully discussed at another time; but we may mention here that, though only of recent introduction, they have met with such favour that over 1200 have already been ordered. The flanging of the four furnace holes and sides of the front plate is effected at one heat by special hydraulic plant. At the back of the stand is a very large steel boiler plate, which is sure to attract attention. It is said to be the largest plate yet rolled, and measures 28ft. in length, 9ft. in width, and is 1⅛in. thick. It is one of a considerable number made for the Fairfield Shipbuilding Company, Limited; and it is noteworthy that several of the Sheffield houses do a good trade in boiler plates with the Clyde, none of the Scotch steel makers being as yet in a position to supply them of the required dimensions for the largest class of marine boilers. A large chemical pan, 9ft. 4in. in diameter, 2ft. 4in. deep, and ⅜in. thick, pressed by hydraulic power from a solid steel plate, and a super-heater plate of Siemens-Martin steel, are also interesting to boiler makers, and display excellent workmanship. Among the steel castings exhibited, a powerful propeller tube stern bracket for a twin screw steamer, and a large propeller blade intended for one of the two Inman and International vessels at present being built by Messrs. J. & G. Thomson, at Clydebank, are noticeable for solidity, finish, and general excellence. We may conclude this notice by calling attention to the fine collection of locomotive crank axles, tyres, springs, buffers, pressed wheels; to a large weldless steel hoop for a chemical furnace; and to the two suspension bridge chain links, similar to those made for the new Hammersmith Bridge. These massive links, with their enlarged heads, may be considered unique products of the rolling mill, as they leave the rolls in a finished state, without requiring any subsequent forging or machining.

Messrs. John Spencer & Sons, of Newburn Steel Works, Newcastle-upon-Tyne, whose steel castings are so widely and favourably known among engineers, have only a very small stand, chiefly occupied by patented specialties such as crank shafts, &c. These are dealt with under the head of marine engineering; and it only remains for us to state that a cast steel locomotive driving wheel centre, 6ft. 6in. diam., and some specimen castings, forgings, &c., will repay examination, and to make some allusion to Messrs. Spencer's latest specialty in the shape of what are called "Newburn homogeneous iron" castings. This homogeneous iron is, according to the makers, a special kind of very soft steel, with a tensile strength of from 22 tons to 25 tons per square inch, and an elongation of 30 to 40 per cent. It is particularly adapted for making castings to replace small and complicated forgings, and for many details of engine work it has a decided advantage over ordinary cast steel in that it will case harden, also in that it generally requires no annealing. The material can, moreover, be forged and welded like wrought iron. The makers keep the process of manufacture a secret; but we understand that they have discovered a method of making castings of soft iron by the addition of a small quantity of some metal—other than aluminium—to the iron scrap in the crucibles. A considerable number of these castings are shown, and to all appearance they seem likely to come into competition with "Mitis" castings, especially as their price is moderate.

Mr. T. Nordenfelt exhibits on the next stand a large and interesting assortment of the well known "Mitis" castings. Mitis metal results from the addition of from 0·05 to 0·1 per cent. of aluminium to melted malleable iron or steel, and by varying the percentage of carbon the metal is obtained of any desired degree of hardness. The effect of the small addition of aluminium is to render the molten metal remarkably fluid, so that it will run freely into the smallest impressions of the mould, while at the same time gaseous bubbles, which would otherwise be a cause of unsoundness, are allowed to escape. The cast material possesses great strength and toughness; and the numerous excellent specimens shown on the stand illustrate the multiplicity of uses to which these castings may be applied. They will, no doubt, meet with wide adoption, in spite of their somewhat high price.

(To be continued.)

BALANCED HYDRAULIC LIFTS.

We illustrate on pages 584 and 585 several forms of hydraulic lifts which are the patented inventions of Mr. Samuel Chatwood, of Chatwood's Patent Safe and Lock Company, Limited, Manchester, the well known firm of safe makers. These lifts are constructed on novel and ingenious principles invented by Mr. Samuel Chatwood, whose mechanical skill and ingenuity will be, no doubt, known to many of our readers. The leading feature of the invention is the introduction of a separate cylinder, fitted with a plunger, and known as the balancing cylinder. This cylinder is connected by means of a pipe with the lift cylinder, and the plungers are so arranged that when one is out to the fullest extent the other is forced home. A fixed quantity of water, which is practically incompressible, is contained within the two cylinders and the pipe connecting them, so that if one plunger or ram is pushed in the other is necessarily pushed out, as the volume of water remains the same. The action is thus like a lever with the fulcrum between the power and the weight—as one end moves up the other end moves down—the extent of motion depending on the position of the fulcrum, while in this arrangement it depends on the relative areas of the two cylinders. The balancing cylinder being weighted, or such pressure being

Digitized by Google

BALANCED HYDRAULIC LIFTS.

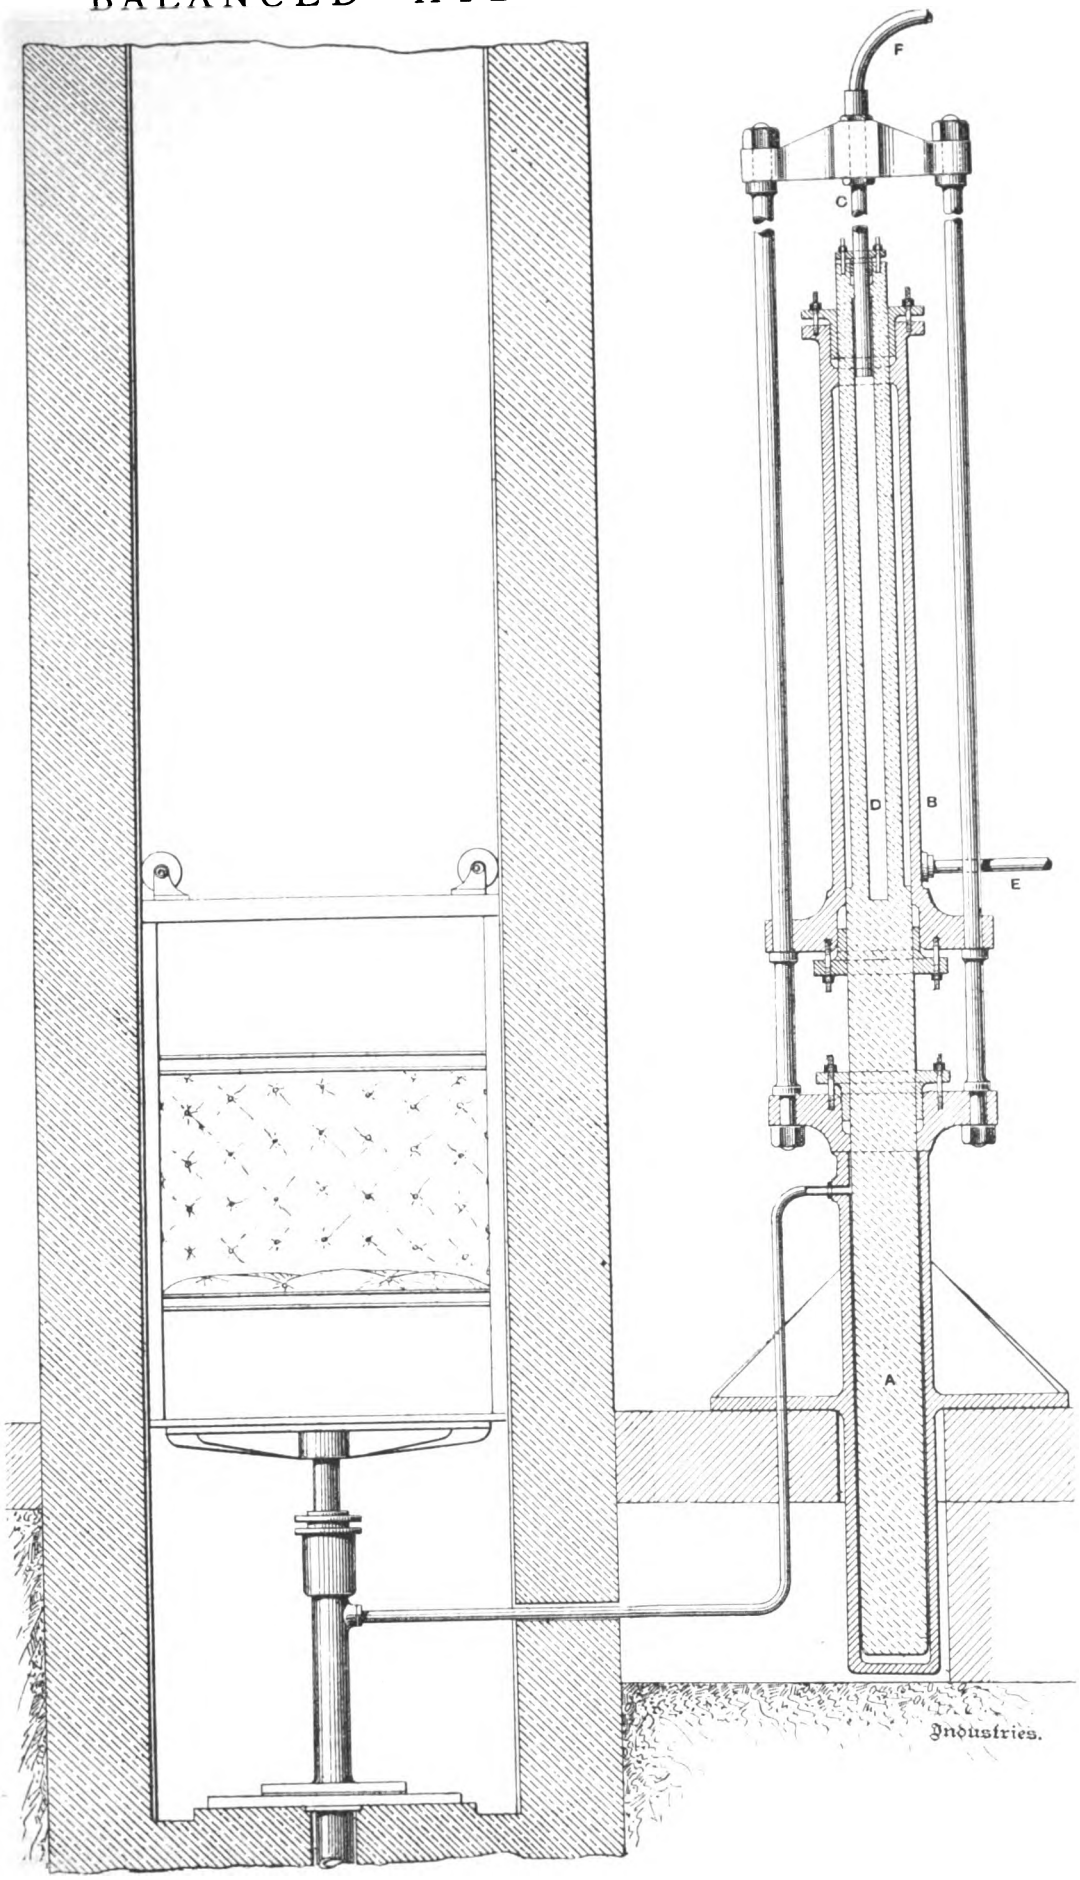

FIG. 1.

applied to one surface of its ram that the weight of the cage and its appliances is just balanced, it is only necessary to apply just sufficient pressure to overcome the friction of the leathers, guides, &c., in order to produce motion of the cage upwards, and to withdraw double this additional slight increment of pressure to bring down the cage. This comparatively slight pressure may usually be obtained from the town water mains. The arrangement is especially useful where a large and tolerably constant load requires to be lifted or lowered when desirable, as in the case of books or cash in bankers' safes. The arrangement is also very useful as applied to passenger lifts. Among the incidental advantages possessed by this system we may mention that it avoids all overhead chains and balance weights, which are not only inconvenient but often dangerous. Another advantage is that the cylinders and rams may be made as small as may be desired, consistent with the necessary strength and stiffness, by properly proportioning their respective diameters. Of course, a great saving of water is effected by this arrangement, as the fixed quantity enclosed between the two pistons or rams is used over and over again, only the small quantity required to produce the difference of pressure being wasted.

Before describing the illustrations in detail it may be well to give a general account of the apparatus and its

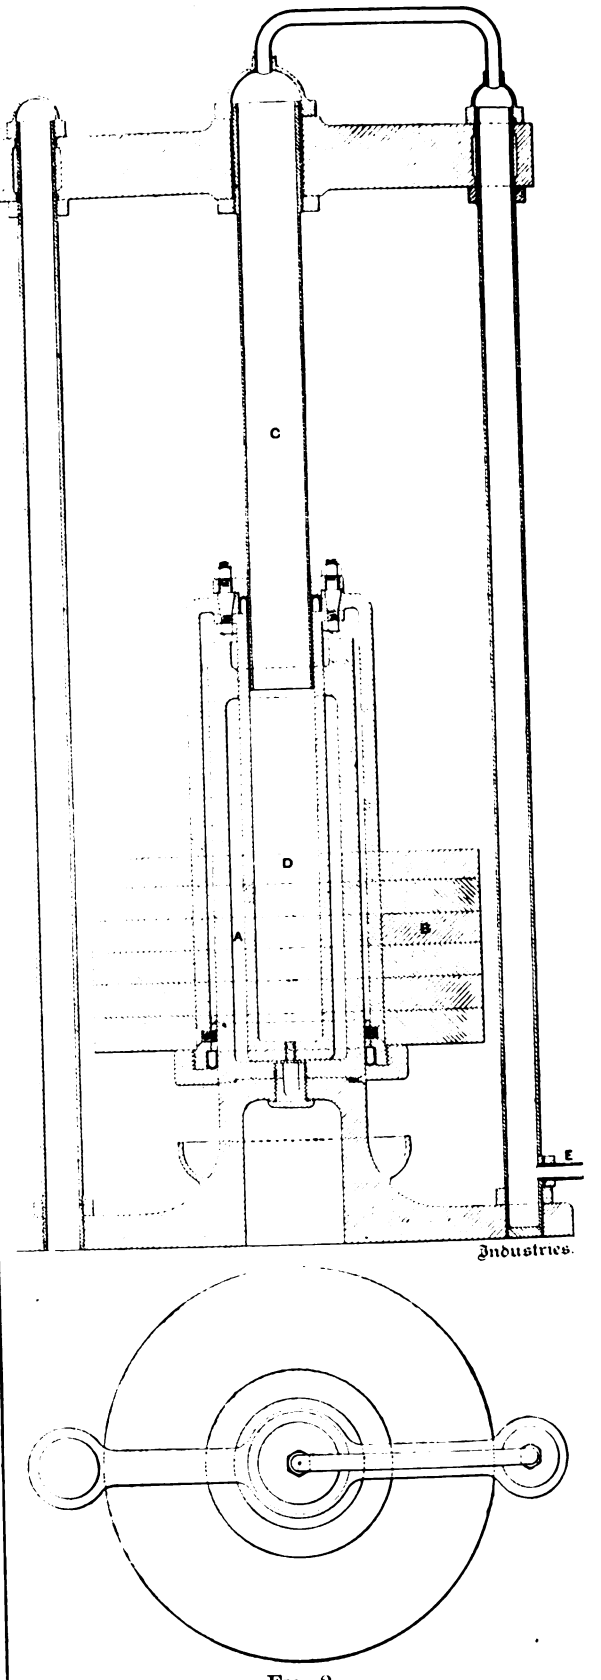

FIG. 2.

action. The cylinder of the lifting ram is connected with the balancing cylinder by a pipe, the respective areas of the two cylinders being suitably proportioned. When the ram of one cylinder is raised, the ram of the other is lowered in exactly the same way as the weights on a scale beam. Suppose the weight on the lifting ram is 1 ton, then to balance it, such a weight must be placed on the ram in the other cylinder as the proportion of the areas of the two cylinders requires. If the ram of the lifting cylinder is in its lowest position, and it is desired to raise it, a further weight must be applied to the ram of the balancing cylinder, so as to overcome the friction of

Digitized by Google

the packings of the two cylinders and the other resistances. The weight having been applied and the ram of the lifting cylinder raised, when it is desired to lower it again the extra weight that has been applied to the balancing cylinder must be removed and a corresponding increase of weight must be brought to bear on the ram of the lifting cylinder, in order to overcome the friction of the machinery. This extra balancing weight may

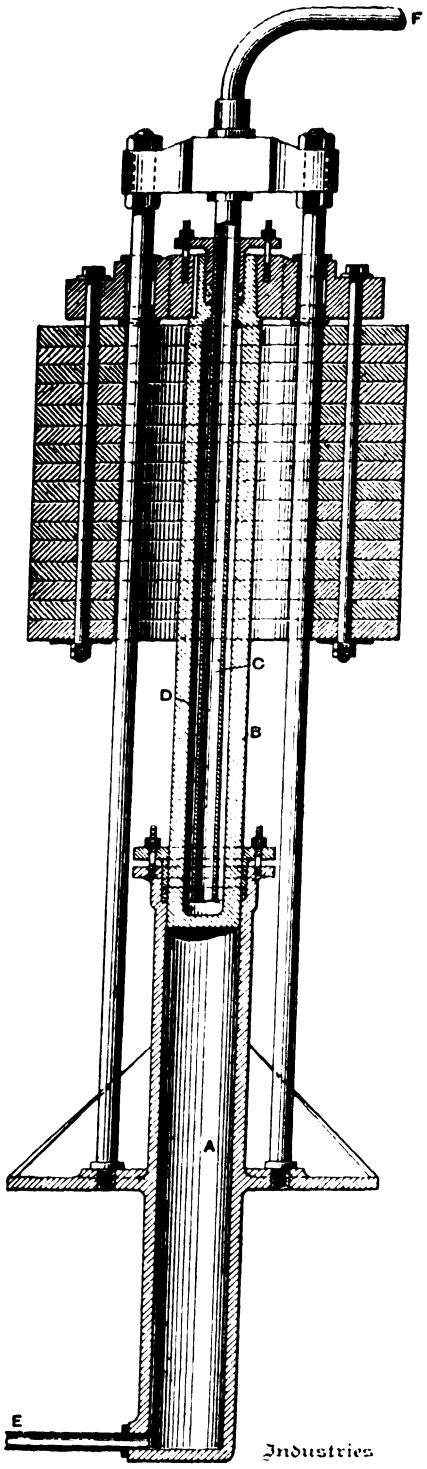

Fig. 3.

virtually be applied to the lifting cylinder by removing a corresponding weight from the balancing cylinder, without altering the weight on the lifting cylinder. Now, if it be supposed that the ram of the balancing cylinder in passing out of its gland is attached to another cylinder, and that this other cylinder is inverted in such a way that it covers, or partially covers, the balance cylinder proper, and at the same time let the upper portion of the balance cylinder be enlarged outside, so as to form a water tight joint with the interior of the inverted cylinder. Then, if the inverted cylinder which is carried by the ram of the balancing cylinder is made very thick, or is arranged so as to carry weights, its weight can be so adjusted that it will always raise the lifting cylinder ram. If the ram of the lifting cylinder has been raised in this manner, and it is desired to lower it again, then in order to remove some of the weight from the ram of the balancing cylinder, water at a suitable pressure is admitted into the space between the bottom of the inverted cylinder and the top of the balancing cylinder. Since this inverted cylinder must, from its position, have an area greater than that of the ram in the balancing cylinder, which latter area must be subtracted from the former so as to give the effective area, a considerable upward pressure is exerted by the pressure water introduced into the inverted cylinder; this water pressing upwards and virtually removing a portion of the weight from the ram of the balancing cylinder, thus causing the lifting ram to descend. Or instead of taking off the unbalanced weight by admitting pressure water into the annular space between the ram and the sides of the converted cylinder, the ram may be used as a small supplementary cylinder open to the available water pressure, which on being open to waste will remove the portion of the lifting weight due to the area of the hollow ram, which serves also as a supply pipe, and by which it is worked. In the former case, the lift will descend when the valve is open to pressure; and in the latter case, when it is open to discharge. The inverted cylinder may or may not be used, according to circumstances. A convenient method of doing this is to use the plunger as a cylinder, and to allow it to work on a hollow ram attached to a fixed crosshead, when the weight on the lift cylinder will be balanced and raised, partly by the fixed weights and partly by the hydraulic pressure on the interior of the ram. By this arrangement it is obvious that a small fixed weight will be required. Fig. 2 shows the weighted inverted cylinder with its plunger used as a small supplementary cylinder. Fig. 1 represents a sectional elevation of one form of cylinder. A is the balancing cylinder, in which a solid ram works through a water tight collar, the ram being continued into another cylinder B vertically over the balancing cylinder A, and working through another water tight collar at the top of this second cylinder. At its upper end the ram is bored

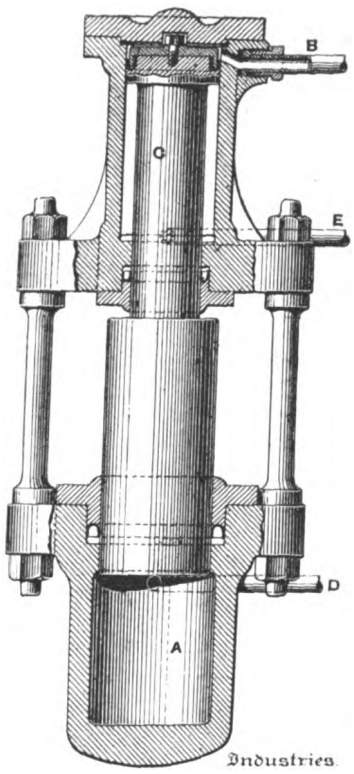

Fig. 4

out so as to form a hollow cylinder, and as the ram is raised, a pipe attached to a fixed crosshead and working through a water tight collar enables water to be supplied to this inner cylinder for raising or lowering the lift. This pipe thus forms a fixed ram for the sliding supplementary cylinder. An annular space round the ram, in the cylinder B, enables such pressure to be exerted on the ram as is required to balance the lift and its load—less friction. The cylinder A is connected by the pipe shown with the lift cylinder, and in this system a fixed quantity of water always remains. Into the cylinder at B water at a high pressure is admitted, which acting on the ram produces a pressure downwards which balances the lift and its luggage or load. The steel tube C supplies water to the small supplementary cylinder which is formed inside the ram, and on being opened to the supply will exert a pressure downwards on the ram and thus raise the lift, while on opening it to discharge the lift will be lowered. Fig. 3 shows an alternative arrangement for balancing the lift and its weights or load by means of fixed weights attached to the ram. Here, as before, A is the balancing cylinder, in which the ram B works. To a crosshead at the top of the ram the weights are attached, which balance the lift and its ram minus friction; these weights taking the place of the cylinder B in Fig. 1. The ram is hollow, thus forming a supplementary cylinder D which has a water tight collar working on the steel supply pipe C. If this pipe is open to supply the lift is raised, and if it be open to discharge the lift is lowered. Fig. 5 shows another arrangement of the cylinders. In this case also, A is the balancing cylinder, and is connected with the lift cylinder by the pipe shown. The ram is continued upwards into a smaller cylinder B, which is always open to the accumulator or service of supply, and balances the dead load minus friction. A crosshead attached to the upper part of the ram is connected by side bars, with a crosshead attached to a ram in a third cylinder C placed vertically under the two cylinders A and B. The cylinder C is open to the accumulator when the lift is being raised, and is open to the discharge when the lift is descending. Fig. 4 shows an arrangement in which only two cylinders

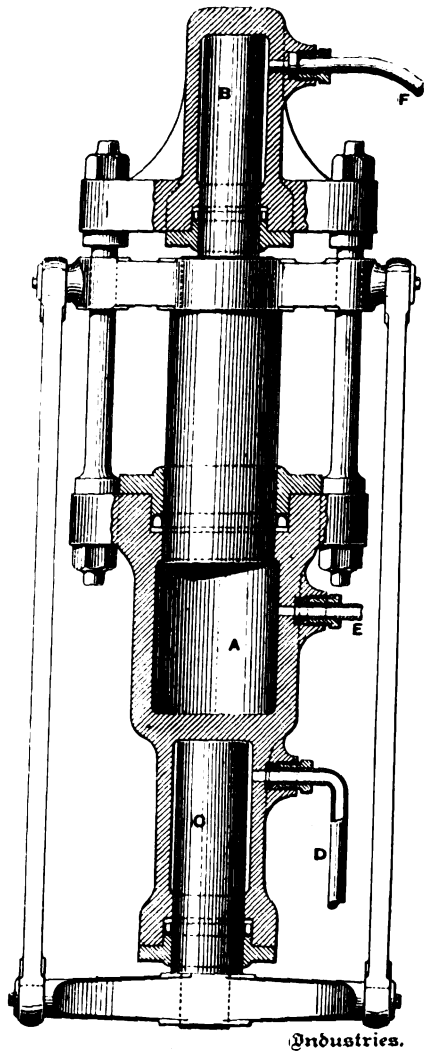

Fig. 5.

are employed. As before, A is the balancing cylinder, and is in free communication with the lift cylinder. The ram is continued upwards into the cylinder C, and at its upper end it is fitted with a piston. The space above the piston is always open to the accumulator or service of supply, and lifts the total load. When the space under the piston is open to the accumulator the lift will descend, and when it is open to the discharge the lift will ascend. Mr. Chatwood's invention, of which various forms have been described above, was patented by him in 1878. Hydraulic lifts constructed on these principles were shown by Mr. Chatwood at the Paris Exhibition, 1878, and several forms were shown at the Manchester Royal Jubilee Exhibition last year, including working models of Chatwood's patent hydraulic balance applied to a banker's strong room, to a passenger elevator, and to a jeweller's window; together with various other models of the hydraulic balance.

THE INSTITUTION OF CIVIL ENGINEERS.

The annual general meeting—to receive and deliberate upon the report of the Council on the state of the Institution, with the annual statement of the accounts, and to elect the Council and officers for the ensuing year—was held on Tuesday, the 29th ult., Mr. George B. Bruce, President, in the chair. It will be within the recollection of the members that a special general meeting was held on the 16th of November, 1886, at which a petition was adopted praying the Queen in Council to grant to the Institution a supplemental charter. In answer to this application, the Institution had received Letters Patent, dated the 3rd of August, 1887, under the great seal of the United Kingdom, extending the power to acquire and hold a hall, messuages, lands, tenements, and hereditaments, from £1,000—as authorised by the original charter—to a sum not exceeding

Digitized by Google

HODSON'S PORTABLE DRILLING MACHINE.

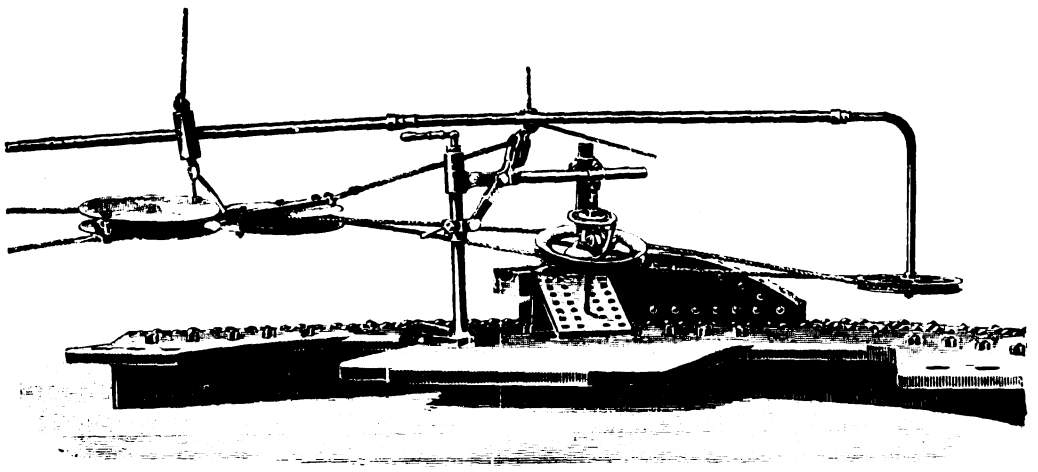

FIG. 1.

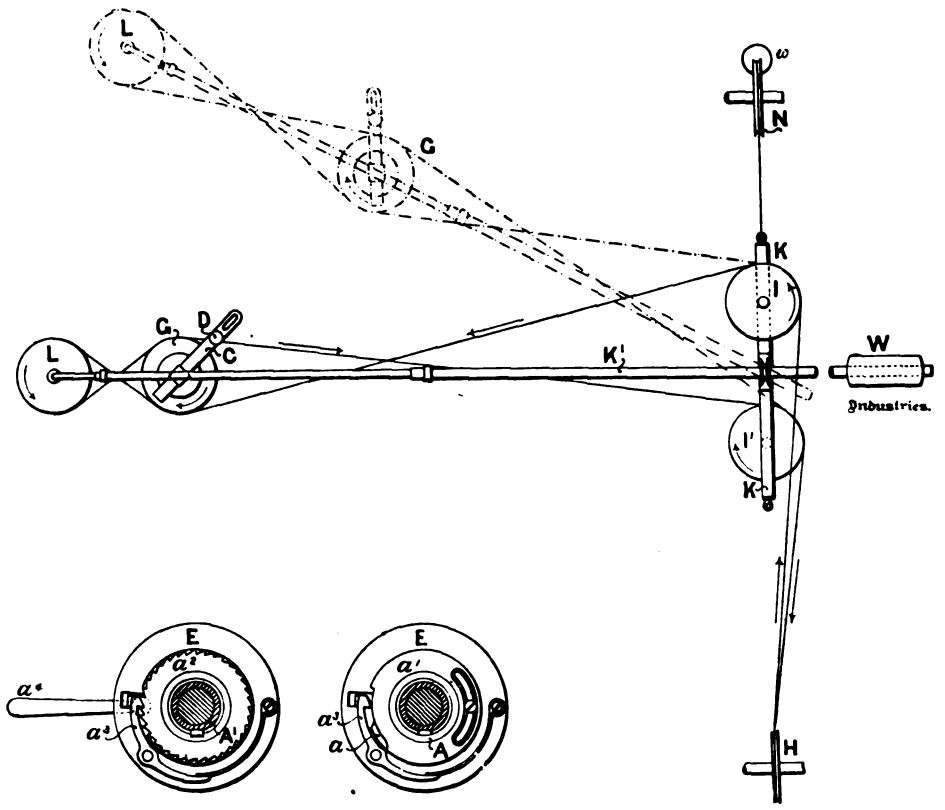

FIG. 2.

£8,000 in annual value. A copy of this supplemental charter had been sent to every member, together with the biennial issue of the original charter, by-laws, and list of members. At midsummer last, the freehold of No. 24, Great George-street, embracing the portion of the premises already occupied on lease, was purchased for £15,000. The Institution was now the owner of three contiguous houses, obtained at a cost of £40,000, exclusive of legal and incidental expenses. In accordance with the recommendation of the last Council, openings had been made between the basements, the ground floors, and the first floors of Nos. 24 and 25. The Council had presented a petition against the Westminster (Parliament-street, &c.) Improvements Bill, which contemplated taking by compulsion the freehold premises above referred to. The result of this petition was the insertion in the Act—which received the Royal Assent on the 23rd August, 1887—of clauses for the protection of the Institution, the substance of which was as follows: The conveyance to the Institution of the fee simple in possession of a plot of land on the northern side of Great George-street, having an area of 11,000 sq. ft.; the payment of a sum of £35,000 as full compensation for the buildings, and for all consequential damage; the use of the present premises for eighteen months after possession had been given of the substituted site and the above payment had been made; and unless within one month after the expiration of twelve months from the passing of the Act a sum of £10,000 should be paid to the Institution as security, the powers of the Act, so far as the Institution was concerned, would lapse. Up to this time, no intimation had been received whether the powers of the Act were to be put in force. Communications having been received from a committee promoting the registration of architects, engineers, and surveyors, inviting the Council to offer suggestions upon a draft Bill to be brought forward this session, that committee was informed that the Council did not intend to take any part in furthering the proposed measure. Later on, however, it became evident that active steps must be taken to oppose the Bill, which vitally affected the interests of the Institution, as well as those of the cognate bodies representing architects and surveyors. On behalf of the Institution a statement of reasons against the measure was drawn up, and this formed the basis of a petition to the House of Commons, which was duly presented by Mr. A. Giles, M.P., V.P.Inst.C.E. As the provisions of the Bill became better known, opposition increased in various other quarters, and, on the second reading, the opinion of the House was so clearly opposed to the Bill that its promoters withdrew it rather than risk a division. During the twelve months ended the 31st of March, 1888, there had been an addition to the roll of 49 members and 183 associate members, the number of non-corporate associates being reduced by 23. The increase had been 4·6 per cent. per annum, as compared with 4·19 per cent. for the previous twelve months. The students had increased by 25. At the date named there were on the books 1617 members, 2458 associate members, 461 associates, 20 honorary members, and 974 students—together 5530. The receipts on account of income during the twelve months under review were £16,071. 12s. 2d.; on account of capital, £4,248. 11s. 2d.; and from trust funds, £433. 15s. 1d. The general expenditure had amounted to £13,956. 10s. 10d., of which more than one moiety constituted the cost of the publications. A sum of £6,476. 18s. 9d. had been invested in the purchase of £5,000 London and North-Western Railway 4 per cent. debenture stock, and the outlay on account of the trust funds amounted to £476. 6s. 11d. These figures constituted the ordinary receipts and disbursements. Owing, however, to the purchase of No. 24, Great George-street, it had been necessary to sell railway debenture stocks of the nominal value of £9,000, and to transfer from the yearly receipts a sum of £4,617. 11s. 3d., to meet this outlay. The papers read at the ordinary meetings had been of more than usual interest, and had given rise to animated discussions and to much correspondence. For some of the papers the Council had awarded medals and premiums to Messrs. R. A. Hadfield, P. W. Willans, Dr. Edward Hopkinson, Messrs. E. B. Ellington, Josiah Pierce, jun., Sir Bradford Leslie, K.C.I.E., and the Manby Premium to the late Mr. Hamilton Goodall. For papers printed in the "Proceedings" without being discussed a Watt Medal and a Telford Premium had been awarded to Professor Dwelshauvers-Déry, and Telford Premiums to Messrs. W. M. Thompson, J. W. Wyatt, and D. Drummond. Advantage had been taken of the increased accommodation to hold exhibitions of models, appliances, instruments, and specimens in connection with some of the subjects which came under discussion, viz.: "Accidents in Mines," "Manganese Steel," and the "Use of the Plane Table in Topographical Surveying." The success of these exhibitions had formed a most acceptable feature of the Tuesday evening meetings of last session, and it was hoped that they might be repeated and further developed as opportunity occurred. There had been twelve supplemental meetings for students, held on Friday evenings, generally at fortnightly intervals. Three of the papers read and discussed had already appeared in the "Proceedings," and five others had been deemed worthy of publication. The Council was glad to notify a distinct advance in the general care and attention devoted to the preparation of these papers, and in the thoughtfulness manifested, as a rule, by those of the students who had taken part in the discussions. Miller Prizes had been awarded to Messrs. D. S. Capper, L. Gibbs, H. M. Martin, J. H. Parkin, A. Chatterton, J. Holliday, A. W. Metcalfe, and R. J. Money. In conclusion, the Council had noticed with pleasure the part taken in the discussions at the ordinary meetings during the past session by the younger members of the profession, which promised well for the future reputation of the Institution and of its proceedings.

The adoption of the report was moved, seconded, and carried, and it was ordered to be printed in the minutes of proceedings. Hearty votes of thanks were then passed to the President, to the Vice-Presidents, and other members of the Council, to the auditors, to the secretaries and staff, and to the scrutineers.

The ballot for Council resulted in the election of Mr. G. B. Bruce, as President; of Sir John Coode, Mr. G. Berkley, Mr. H. Hayter, and Mr. A. Giles, M.P., as Vice-Presidents; and of Mr. W. Anderson, Mr. B. Baker, Mr. J. W. Barry, Sir Henry Bessemer, F.R.S., Mr. E. A. Cowper, Sir James N. Douglass, F.R.S., Sir Douglas Fox, Mr. C. Hawksley, Mr. J. Mansergh, Mr. W. H. Preece, F.R.S., Sir Robert Rawlinson, K.C.B., Sir E. J. Reed, K.C.B., F.R.S., M.P., Mr. W. Shelford, Mr. F. C. Stileman, and Sir William Thomson, F.R.S., as other members of the Council. The session was then adjourned until the 16th November.

HODSON'S PORTABLE DRILLING MACHINE.

THE increased size of iron structures, and the greater accuracy in workmanship required, render the advantages of portable drilling machines obvious. The days when the rivet holes in boiler plates were brought to meet by drifting, prising, and rimering may be said to have passed, and for the best modern work the holes in the two plates must be drilled together, which necessitates either the bringing of the work to the drilling machine, or the employment of some kind of portable apparatus, the latter expedient being evidently preferable, because not requiring the handling of heavy masses. We illustrate herewith an apparatus devised for this purpose by Mr. Richard Hodson, manager at the Thames Iron Works, for drilling, boring, tapping, or screwing holes in boilers, bridges, pontoons, and other structures. Figs. 1 and 2 show the general arrangement of the machine, and the rope gear by which it is driven, and Figs. 3 and 4 show details of the drilling machine itself. We will first describe the latter, and then pass on to notice the ingenious method by which Mr. Hodson transmits the power from a countershaft to the drilling machine without interfering with its perfect portability. In Figs. 3 and 4, A A¹ is a compound drill spindle bored out to receive the drill B, the cylindrical part of which is notched, and fastened in the usual way by a locking pin. The holder A, which has not been cross sectioned in Fig. 4 for the sake of clearness, is threaded internally to receive the threads of the screw spindle A¹, which is centred by means of a conical head held in an abutment C¹, and the collar F. To prevent the spindle from dropping out, the head is undercut, and held in place by the collar pin *c*. The abutment C¹ is carried, and can slide, on the arm C; it is, moreover, connected by means of the bar F¹ to the bearing F. The abutment C¹ can be clamped in any position on the bar C by means of the screw and handle on the top. The bar C itself can be placed at various angles by means of the screwed sleeve C², the fulcrum D², and connecting link C⁴. The inclination of the bar C is set by simply turning the handle on the top of the sleeve C², and thus a horizontal and angular adjustment is provided in addition to the vertical adjustment of the drill. The upright D¹ is clamped to the piece of work operated upon. Motion is transmitted to the drill by means of a rope passing on either side of the grooved pulley G. The rope does not lie at the bottom of the groove, but takes its bite against the inclined surfaces. Within the rope pulley, which is made in halves, there is the speed reducing gear, consisting of four spur wheels, the wheel 1 being keyed to the drill holder A, the wheel 2 forming part of the sleeve E, whilst the wheels 3 and 4 are cast in one, and revolve loose on a stud S, which is fixed to the pulley. When this pulley rotates and the sleeve E is held tight in the bearing F, rotary motion is communicated to the drill holder by reason of the wheel 2 acting as a fulcrum over which the wheel 4 rolls, thus causing the rotation of the wheel 3, which, being in gear with wheel 1, causes it to revolve at a slower rate than the pulley G,

Digitized by Google

HODSON'S PORTABLE DRILLING MACHINE.

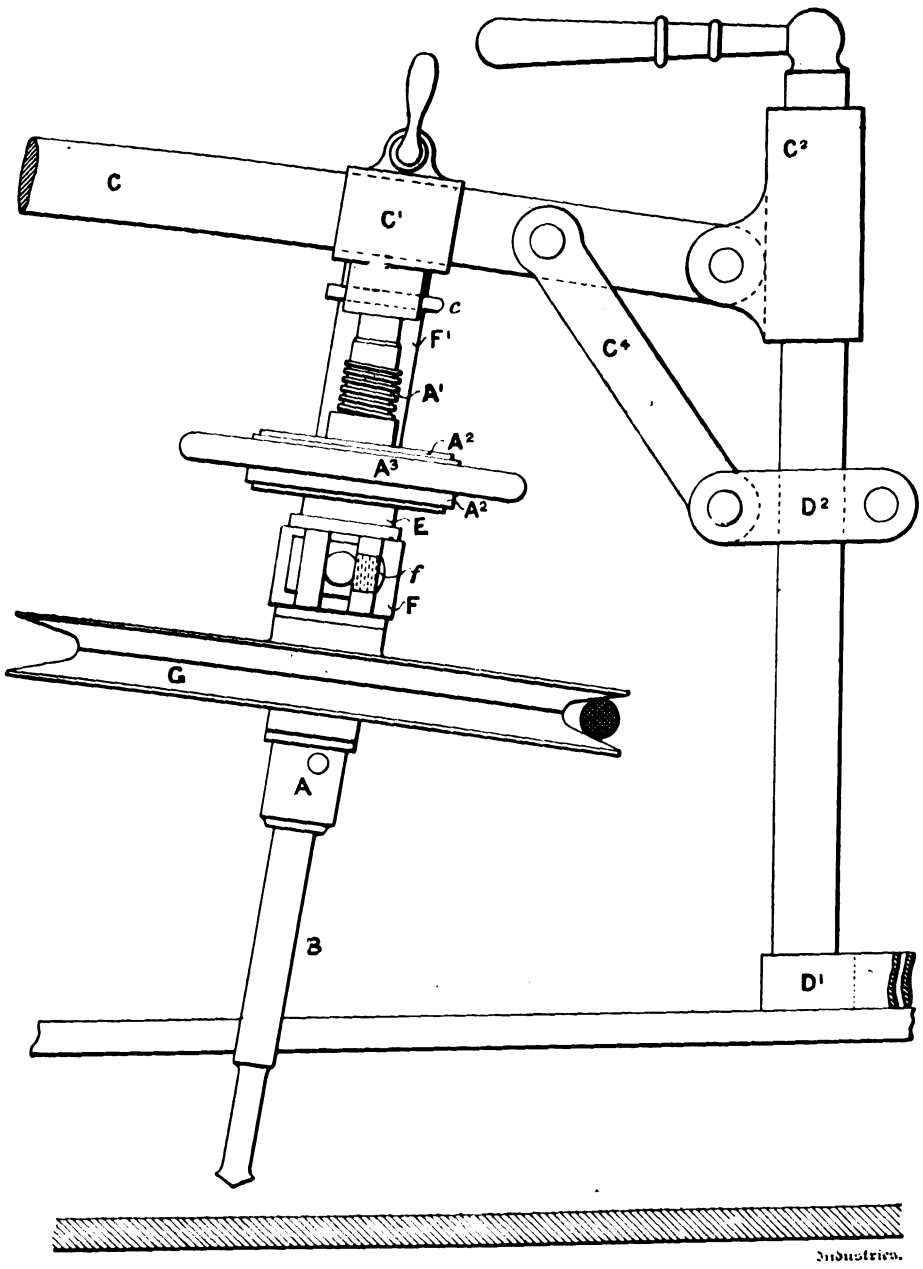

FIG. 3.

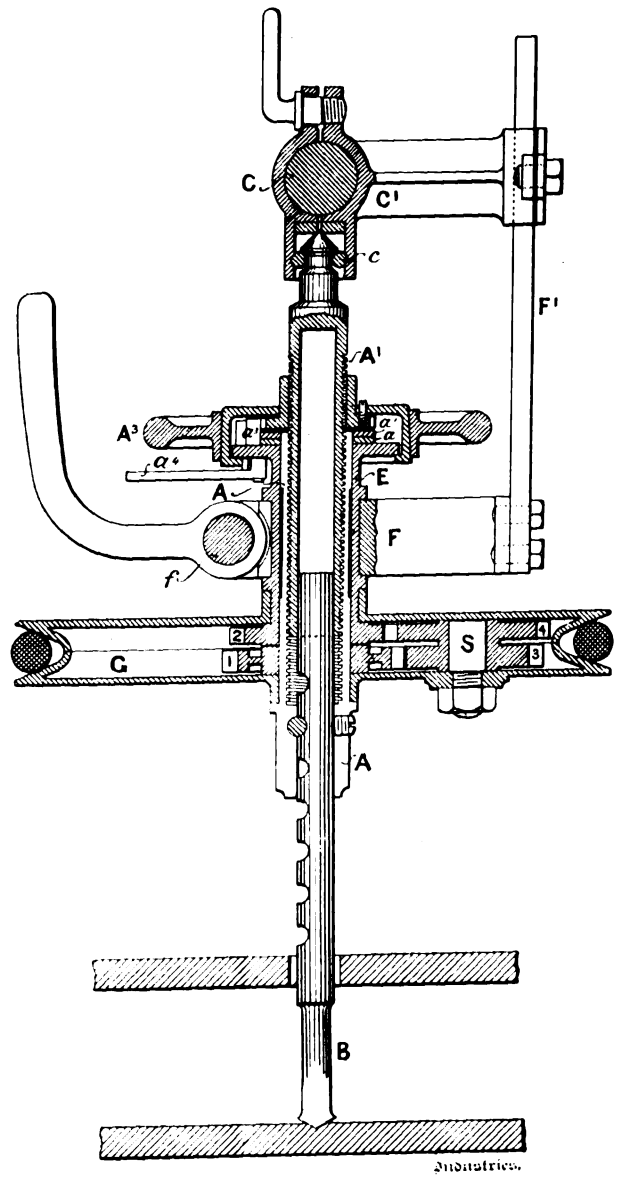

FIG. 4.

the reduction in speed being determined by the number of teeth in the wheels. The speed of the drill is varied by inserting another set of wheels into the pulley G. To stop the drill without stopping the rope, it is only necessary to move the curved handle above the rope pulley on its pin *f*, which slackens a screw, and thus takes off the friction between the bearing F and the sleeve E, allowing the latter to revolve with the pulley G. It is thus possible to instantly stop and start the drill as may be required by the simple movement of a lever. The feed motion may be given either by hand or automatically. The upper part of the screwed spindle A^1 is provided with a longitudinal groove in which slides a feather made fast to the sleeve of a ratchet wheel a^2 (Fig. 2) situated immediately above the two notched discs $a\,a^1$. The disc a^1 is keyed to the upper end of the tool holder A, and the disc a is made fast to the disc a^1. The ratchet wheel is free to slide up and down the screwed spindle, but must participate in its rotation, and it is locked in position by means of a pawl a^3, which is pivoted in a flange of the sleeve E and controlled by a lever a^4. The parts just described are enclosed within a cover made in halves, over which is placed a hand wheel A^3. By turning this hand wheel the drill can be advanced or withdrawn, as desired. The apparatus, however, serves also for the automatic feed motion. While the pawl is engaged with the ratchet wheel the tool holder A advances the drill slowly to its work; but on tripping the pawl within the gear by means of the lever a^4 this advance ceases. For automatically tripping the pawl during the operation of feeding, the notched discs $a\,a^1$ are used. Whilst these discs are in the position shown in Fig. 2 the pawl is in gear with the ratchet wheel a^2, and feeding takes place; but during the continued rotation the notch of the disc a^1 raises the pawl a^3 out of gear with the teeth of the ratchet wheel a^2, and thus interrupts the feed motion until the notch of the disc a has come round and allowed the pawl again to drop and engage with the teeth of the ratchet wheel, when feeding will again take place. The action is thus precisely similar to that of an ordinary ratchet brace, where from time to time the workman advances the tool holder by a definite amount. In the present case the amount of advance is determined by the length of the notch, which is regulated by the angular position of the two discs $a\,a^1$. This position is fixed by means of a screw working in a slot, as shown in Fig. 2. The feed motion is also automatically stopped when the rotation of the drill is stopped by turning the bent lever already mentioned. In this case the sleeve E will be carried round until the cam lever a^4 strikes the upright F^1, and thus lifts the pawl out of gear.

Mr. Hodson's portable drilling machine is specially adapted for drilling holes in line through two plates some distance apart, as shown in Fig. 4, such, for instance, as the shell and furnace plate of a boiler. The hole is first drilled through the shell, the drill is then liberated, advanced through the holder, and fixed again in position to drill the furnace plate. When this operation has been performed the drill can be replaced by a tap, which is, however, not fixed in the drill holder except in so far as it is forced to participate in its rotation. By this means two holes may be drilled and tapped without moving the apparatus from its position.

The arrangement of the rope driving gear will be understood from the general view (Fig. 1) and from the diagram (Fig. 2). Power is supplied from a countershaft and rope pulley H, the rope passing over the pulley I^1, partly round the pulley of the drill G, then round the pulley L at the end of a telescopic arm K^1, then partly round the pulley G on the other side, over the pulley I, and back to the pulley H on the countershaft. The pulleys I I^1 are mounted upon the cross piece K, which also carries the telescopic arm K^1 with its counterbalance W, and the rope is kept in tension by means of a weight *w* passing over a pulley N, which tends to draw the cross piece K away from the countershaft. The telescopic arm K^1 is carried in a cross piece K by means of a swivel joint, so that it may be shifted into any convenient position, as indicated by the dotted lines. By this means the drill is rendered portable within a radius of from 20ft. to 30ft. without shifting the pulley H on the countershaft or altering the length of the driving rope.

The advantages of this drilling machine are its extreme portability and lightness, one man being able to carry it about and fix it; its great power, due to the multiplying gear within the rope pulley, so that large holes may be drilled with only a few pounds tension on the driving rope; its accuracy, there being no unbalanced tension from the rope on the drill spindle; and its automatic action and facility of control. This machine is in use at the Thames Iron Works, where we had recently an opportunity of seeing it.

ITALIAN CUSTOMS DUTIES.—The Foreign Office has received information that a notification has been issued by the Italian Director-General of Customs, that invoices will no longer be accepted as proof of the origin of goods imported into Italy. All goods, in order to enjoy conventional treatment, must be furnished with a certificate of origin, except such as have come straight from the country of production or have been merely transhipped in a French port.

FOREIGN INDUSTRIES.

(From our own Correspondents.)

PARIS, 12TH JUNE, 1888.

THE IRON MARKET.—The iron market is calm, but not dull. There is a steady current of business arising from the present needs of consumers, but the speculative spirit has wholly disappeared from the market. This state of things is likely to continue. The insecurity of the political situation tends to check the expansion of trade, and as no immediate improvement is to be looked for in this respect, the year will probably pass away without bringing that degree of activity which the events of the third and fourth months led us to hope for. The situation, however, is not one to complain of. Trade has recovered in a sufficient degree to make it fairly remunerative to the manufacturer, and this recovery is likely to be maintained. It is safe to predict a steady current of business till the end of the year. The Paris market is still unsettled, merchants offering bars at £5. 12s. and joists at £5. 4s.; but in the provinces the rates are firmly upheld. Old rails fetch £3. 6s. a ton.

THE GOVERNMENT AND THE WORKING CLASSES.—The acts, both of the Legislature and of the Executive, evince a desire on the part of the Government to conciliate the working classes. Some of the concessions accorded, however, are of a nature to cause discontent among the employers of labour, and to obstruct the natural development of industry. Thus, the *Journal Officiel* has published a decree regulating the conditions according to which associations of working men are to be permitted to execute Government work. Such associations may tender publicly, or enter into contracts privately. They are relieved of the necessity of providing caution money for contracts below £2,000. When there is equality in the tender between a workmen's association and a contractor, the former is to have the preference, and the association may draw money on account every fortnight.

THE EXHIBITION OF 1889.—The Minister of Commerce has just been informed that Finland will take part in the great Exhibition of next year. An influential syndicate of Finnish manufacturers has been formed to promote this object. It is also officially announced that the United States will exhibit on a large scale. American manufacturers of mining machinery will be strongly represented. In bringing this class of machinery to Paris, the exhibitors are, it is said, aiming not so much at the European as at the South American, South African, and Australian markets. In electric motors, and systems of transmitting power by electricity, the United States section will be particularly strong. It is proposed by an American firm to put up a 100-stamp mill at the Sheba Mine at Barberton, South Africa, and to drive it by electricity generated at a waterfall ten miles distant. It is probable that a working model of this mill will be exhibited here.

PROSPECTS OF THE HOP CROP.—The hop market is becoming agitated. The dry weather following on a cold spring is beginning to tell unfavourably upon the new crop. The bines are yellow and weak, and growers are becoming alarmed at the prospect before them. In consequence of these apprehensions, a brisk demand has sprung up for old hops, for which higher prices are readily paid. From Alsace it is reported that a large proportion, fully half the possible yield, of the growing crop has already been sold at prices varying between 60fr. and 70fr. (55s. and 63s.) per cwt. These sales are evidence of a want of money on the part of the growers, a want which is more felt every year.

THE DECANVILLE LIGHT RAILWAY.—Visitors to the Laon Exhibition will find something to interest them in the light railway or steam tramway laid down by M. Decanville from the railway station to the exhibition building, a distance of a mile and a quarter. The gradients are as steep as 6 in 100, and some of the curves have a radius of only 26 metres. The rails are laid on the highway; their weight is 9·5 kilo. per metre run, and the gauge of the line is 60cm. The whole distance was laid by forty men in four days. A compound locomotive on the Mallet system is used, weighing 12 tons, inclusive of water and coal. There are three cars in the train, each constructed to carry thirty-two passengers.

BERLIN, 11TH JUNE, 1888.

THE COAL MARKET.—The steady improvement in the price of all classes of coal and coke still continues, and as regards coke the immediate effect has been to increase the number of ovens at work. A change of considerable importance has taken place in the Upper Silesian coal industry, viz., the purchase by Messrs. Friedländer & Co. of the extensive colliery hitherto belonging to Count Henckel von Donnersmarck, which has an annual production of 800,000 tons. The same firm has also acquired the colliery of Count Schaffgot in the same district, and as these two collieries are amongst the most important in Upper Silesia, the firm is likely in future to control the market.

ACTIVITY IN THE COAL TRADE.—The official report of the Dortmund Coal Club on the state of the market says that business is still animated, and in some directions increasing, though we have arrived at a season when trade is usually dull. It is further stated in confirmation of this remark that many colliery companies have sold the whole of their output for the present year.

THE IRON MARKET.—The general tone of the iron market is firm, but the amount of business being done is less than in the corresponding period of the previous year. The rolled iron syndicate of Mid-Germany have decided at their last meeting to maintain the present prices. The most important reason for the refusal of the society of Westphalian wire nail makers to join the German wire nail syndicate, to which I referred last week, has now transpired. It appears that the Society has a specially good foreign connection, and does not want its customers' names to become known to the syndicate. The industrial importance of the present crisis in the wire nail trade may be inferred from the fact that if the Society succeeds in breaking up the syndicate, the present average price of 160s. per ton for wire nails would inevitably recede to its former low level of 120s. The loss would be most felt by the wire nail makers of Hamm, who produce collectively about 24,000 tons of nails annually. In Upper Silesia business is normal, and the output of crude iron is quite up to the demand. The erection of new blast furnaces and accessory apparatus at the works of the Falvahütte and Friedenshütte is making rapid progress, owing to the favourable weather. The rolled iron syndicate contemplate a further rise in prices for the third quarter of the year, and a new sales bureau at Frankfort-on-the-Main is also projected. The recent tenders for steel rails and steel sleepers invited by the Bavarian railway administration are instructive. The supply was for 13,500 tons of rails and 11,100 tons of sleepers, and the order has been divided amongst the following firms: For rails, Messrs. Stumm Brothers, of Neunkirchen, 3600 tons at 117s. 5d.; the Aachener Hütten Aktien Verein, 3600 tons at 117s. 5d.; Bochum, 3000 tons at 117s. 9d.; the Rheinische Stahlwerke, of Rührort, 1800 tons at 117s. 7d.; and the Phœnix Company, of Laar, 1500 tons at 117s. 8d. For sleepers, Messrs. Stumm Brothers, 3000 tons at 119s. 6d.; Bochum, 2640 tons at 119s. 5d.; De Wendel & Co., 1500 tons at 119s. 10d.; the Phœnix Company, 1320 tons at 119s. 6½d.; the Hösch Works, of Dortmund, 1320 tons at 119s. 7d.; and the Rheinische Stahlwerke, 1320 tons at 119s. 3d. These prices are free on rails in Mannheim, and the greater part of the orders must be filled between March and July next year, the remainder before December. No foreign firms have tendered in this competition. The Cologne railway administration have asked tenders for fourteen tender locomotives and fifty-nine waggons of various sizes. The offers received from private firms were throughout lower than those of the State railway shops. For three coupled tender locomotives, Henschel, of Cassel, tendered lowest with £965 each.

GERMANY'S FOREIGN TRADE DURING APRIL.—The statistics recently issued concerning the import and export trade during the month of April of this year are by no means encouraging to German industry. In nearly all branches of the iron trade the exports have receded as compared with the same month of the previous year, the deficiency being most felt in crude iron, bar iron, iron and steel wire, and zinc. For rolled iron and wire nails the returns are somewhat more favourable, but the decrease in the export of crude iron is very great. In April, 1887, there were exported over 25,000 tons of pig, whereas in the same month of the current year only 9000 tons were exported. The exports of cement, coke, and iron ores have, however, increased. The imports show an increase in rye, oats, copper, tin, and cotton.

VIENNA, 11TH JUNE, 1888.

PAPER.—The present position of the paper industry throughout Austria is by no means satisfactory. One of the largest mills was forced a short time ago to go into liquidation, and another large mill, which used in former years to pay good dividends, is now unable to pay its shareholders any dividends at all. Generally speaking, the paper mills manage with difficulty to pay even the interest on their capital expenditure, to say nothing of profits, and this state of things is ascribed partly to overproduction, and partly to excessive competition and cutting of prices, which are, to a certain extent, encouraged even by the Government and public administrations. It has of late become the rule to give the orders to those firms who have sent in the lowest tenders, quite irrespective of the reputation and standing of these firms, and the result is that the quality of the paper supplied under these contracts becomes worse from year to year. I have recently heard of a case where a Government office had to spend a large sum on mending official documents written on paper which was supplied only three years ago, and thus the saving effected in the acceptance of the lowest tender becomes to a great extent illusory. Some of the more respectable paper mills are now trying to mend matters by forming a syndicate of paper makers, which would regulate quality, prices, and quantity produced; and a circular has been issued to the paper mills in Austria-Hungary with this object. Of the 267 mills applied to, only twenty-two have, however, agreed to the proposal, and thus the project must be considered as having failed. It is now proposed to form six local syndicates in various parts of the country, each to select a representative, who will join the general syndicate, and this proposal seems to be more favourably received.

THE IRON MARKET.—The general tendency of the market is quiet, and there is every indication that business will not revive again during the summer season. On the whole the spring season has been bad, and has not fulfilled the expectations which were entertained at the beginning of the year. The sudden demand for building iron which then set in was only of a temporary nature, and the sales of girders, joists, and special sections for building purposes have been less this year than during the same period in the previous year. As a set off for the smaller volume of business, the prices have on the whole ruled rather higher; but the difference was not sufficient to make up for the loss in volume. The present demand for crude iron, merchant bars, and fine sheets is very feeble. On the other hand, heavy sheets still continue to be in good request. Engineering works, especially those in Bohemia and Moravia, are busy with plant for sugar factories, being either new machinery or repair jobs. Some small orders for railway waggons have been distributed during the last week amongst a few of the Austrian waggon works. These orders will help them to tide over the dull season.—The proposed railway line (Eisenerz-Vordernberg) has at last passed the Parliamentary stage, and will soon be taken in hand. When completed, this line will form a very valuable aid to the Styrian iron industry, which has for the last few years been very much depressed.—On the 1st of this month an agreement was arrived at between the Austrian makers of wire and wire nails, under which the price of both articles will be raised 10fl. (about 16s.) per ton. The agreement is equivalent to syndicating this trade, a measure which appeared almost inevitable in view of the steady decline of prices which has taken place within the last ten or twelve years. In 1875, the average price of wire was 232fl. per ton, and in 1878 it was 178fl., whilst in 1881 it had sunk to 157fl. In the following two years there was a slight recovery to 167fl., but then prices again began to drop until last year, when they reached, for wire and nails, the low level of 148fl. From these figures it will be seen that the rise resolved upon by the syndicate will only bring the price back to the average of 1881.

EXPLOSIVES.—The manufacture of explosives has assumed considerable proportions in this country, especially as regards gelatine dynamite and an explosive called rhexite. The first is made by the Nobel Company, and the latter by Messrs. Borkenstein & Co., of St. Lamprecht. The composition of these explosives is, according to a technical committee instituted by the War Office, as follows:—

GELATINE DYNAMITE.	Per cent.
Nitro-glycerine	64
Dinitro-cellulose	2·47
Soda saltpetre	24·85
Wood pulp	7·73
Soda	·57
Ferruginous clay	·38

RHEXITE.	Per cent.
Nitro-glycerine	61·4
Nitrated wood	9·1
Wood pulp	12·6
Potash saltpetre	16·9

Both of these explosives are similar in action and require treatment similar to the old form of kieselguhr dynamite.

PORTABLE ELECTRIC LIGHT PLANT.—Messrs. Siemens and Halske, of this town, have constructed an electric light car containing boiler, steam dynamo, and accessories, which weighs without coal or water 3 tons 8cwt. Steam is supplied by a vertical boiler of 90 sq. ft. heating surface. The dynamo is direct driven by an inverted engine developing 9 h.p. It has a Gramme armature, with internal poles of the type which you illustrated some time ago. The output is 90 ampères at 55 volts pressure, and the makers claim that they obtain one electrical h.p. with an expenditure of 44lb. of feed water per hour.

BRUSSELS, 12TH JUNE, 1888.

THE COAL MARKET.—Coal for industrial purposes and for coking is dear, and stocks generally are smaller than is usual at this season. The demand for household coal has, however, decreased. At Charleroi and in the central districts unscreened industrial coal is quoted at 6s. 5d. to 8s., and coke at 12s. At Liège rates are rather higher. From that district considerable quantities of coal are being sent to Paris. At Mons unscreened coal is quoted at 7s. 7d. to 8s. The situation is very favourable, and promises well for the period when contracts will have to be renewed. The contracts for briquettes for the Ostend mail steamers have been given to M. Felix, of Haynin, and to the Houillères-Unies, at 9s. 11d. and 10s. 4d. per ton respectively.

THE METAL MARKET.—There is now less difficulty in obtaining pig iron, and stocks are becoming larger. Sellers, in consequence, have to make concessions. This is fortunate, as the exceptionally high prices which have been ruling have had an injurious effect on the export trade in finished iron. The prices of 38s. 5d. to 40s. for white pig, and 43s. 2d. to 44s. for grey pig, are now looked upon as the maximum rates. Luxemburg pig is quoted at 38s. 5d., or about 42s. 8d. delivered at Charleroi. The syndicate price of merchant iron is maintained, no sales being made in the home market at less than 96s., or for export under 92s. The price of No. 2 sheets is 120s., and of large plates, 112s; steel sheets are 140s. Business in sheets is active, but for small iron the demand has decreased. Large quantities of iron ore from the Haute Moselle are being imported into the Charleroi district. It forms about 25 per cent. of the total ore used, and this proportion is likely to increase. With respect to the contract for Goliath rails, to which I referred in a recent letter, although some complaints have been made in industrial circles at part of the contracts having gone to the French works, there is no doubt that had our Government declined to accept the tender, the French would have retaliated when an opportunity offered. The Dyle-Bacalan works have received a contract for fourteen locomotive tenders for the State railways at £2,740; La Métallurgique Works quoted £2,869.

THE EXHIBITION.—The inauguration of the Exhibition by the King took place on Thursday last, when speeches were made by the Foreign Minister, and by the President of the Exhibition, in reply to which His Majesty pointed out the importance of promoting the interests of home industries. The King then went through the various sections, and was presented by M. Muzet, the French delegate, with a magnificent Sevres vase. In the Belgium section he was received by Comte A. d'Oultremont, the Commissioner-General. He was taken through the machinery gallery by the engineers, Messrs. D. Robinson and H. Delchambre, two of the large engines being at work. The first engine which was ready in this department was one of 50 h.p., made by M. Heinrichs, of Hodincourt-lez-Verviers. The King showed considerable interest in the exhibits of Messrs. Westinghouse. The electrical section was under the charge of M. Bandsept. A part of the electric lighting, viz., that of the Electrique Company, was ready. The Thomson-Houston Company have an 80 h.p. high speed engine, two dynamos respectively for 45 and 35 arc lamps of 10 ampères, and a plant for electric welding. Messrs. Ganz & Co. have a high tension alternator of 25 ampères and 1000 volts, supplying 200 glow lamps. The Khotinsky Company show two of their storage batteries, each for 250 lamps, and a Toury dynamo. Buckaert & Schuckert have six dynamos and a military search lamp. The Société Industrielle exhibit various sizes of the Lahmeyer dynamo, some in conjunction with 7 ampère arc lamps. In the English section, which looks very well and which is complete, Mr. Lee Bapty received the King. This section is lighted by the Brush Corporation. The honours of the German section were done by M. Corneli, those of the Austro-Hungarian section by Consul-General Duckers, and of the Italian section by Conte Miraflore. There were 50,000 visitors on this day, and the Exhibition promises after all to turn out a success.

DÜSSELDORF, 11TH JUNE, 1888.

THE COAL TRADE.—Though we are in the midst of what is usually the dullest season of the year, the coal trade is characterised by great activity and rising prices. The demand for present consumption is strong, and consumers and merchants are seeking to contract far forward, in anticipation of larger requirements. Production is being pushed to the utmost of what the pits are capable, hampered only by an insufficient supply of railway trucks. The quantity of coal daily dispatched from the Ruhr district averages about 9000 truck loads. This strong demand for fuel in the summer season is the best possible evidence of reviving trade throughout the country. Notwithstanding the larger output of the home mines, more foreign coal is being purchased. The imports in the first four months of the current year amounted to 2,226,778 tons, against 2,053,731 tons in the corresponding period of 1887, an increase of 8·43 per cent. This increase is chiefly in the trade with England. The shipments of British coal to Germany down to April 30th, amounted to 631,580 tons, against 576,157 tons last year. The exports of German coal in the four months reached a total of 3,242,318 tons, against 3,182,759 tons last year, an increase of 1·87 per cent. The ratio of imports to exports is for the current year 0·687; that is, for every ton of German coal sold to foreign consumers, 0·687 ton of foreign coal has been purchased for consumption in Germany. Last year the ratio was 0·645 ton.

THE IRON MARKET.—The iron market is on the whole steady, the current of business being fairly strong, and prices firmly maintained; but the trade in pig is dull, and there are indications of greater languor to come. Consumers, who, for the most part, have provided for their probable wants in the next four months, exhibit an unwillingness to speculate further; yet, as the cost of ore and coke continues to increase, higher prices for pig are expected. The circumstances of the finished iron trade, however, do not justify another advance; on the contrary, they call for lower rates. It has become painfully clear that if relief be not speedily afforded, the export trade will be utterly ruined. An incident of some significance occurred last week. A Frankfort firm offered to sell 10 per cent. spiegel pig 10s. a ton below current rates for delivery at the end of the year. This fact points to a belief, on the part of these merchants at least, that the inevitable collapse is not a very distant event. The manufacturers, however, have shown their determination to maintain their prices to the last moment, by combining to boycott the Frankfort firm during the remainder of the year. The consumption of pig iron in Germany in the first four months of the year, estimated from the production and imports, less the exports in that period, amounted to 1,400,305 tons, against 1,157,847 tons last year, an increase of 242,458 tons, or about 21 per cent. Makers of bars and sectional iron are busy on old orders, but new work is being booked slowly. The trade in joists is animated. A somewhat brisker demand has sprung up for wire, both on home and foreign account. Efforts, likely, it is said, to prove successful, are being made to save the wire nail syndicate, by inducing the outstanding Westphalian firm to join it.

LILLE, 12TH JUNE, 1888.

TEXTILE MANUFACTURES.—There is not much that is new to report in the state of the trade in textile goods, dulness continuing to prevail. Here and there, however, we see a partial recovery. Thus, at Armentières the week has been a good one in the linen goods trade, a fairly brisk demand having sprung up within the last few days. This revival is probably due to the activity prevailing in the flax and yarn markets since it became evident that the growing crop must be a light one. There is but little life in the cotton goods trade. In spite of favourable weather, business at Rouen is very dull. The buying is not sufficient to absorb the production, which is already considerably restricted. Manufacturers complain bitterly of the languid tone of affairs. In woollens there is scarcely more life, considered from a point of view embracing the whole trade. In one or two classes of goods, fancy articles, there is some activity, but the long expected revival is delayed. The Lyons silk goods trade is dull and languid. Manufacturers are altogether dissatisfied with the amount of business transacted in the month of May. The favourable accounts received from nearly all the silk-producing localities point to lower prices for the raw material. This circumstance tends to restrict the trade in woven goods.

FLAX AND YARN MARKETS.—The activity which characterised the flax and yarn markets last week is maintained, and even increases. The prospects of the new crop are very discouraging. It is stated by a competent authority that even with favourable weather the yield must be much below the average. Rain has fallen in considerable quantity in the last two or three days. All home grown flax offered for sale has been eagerly bought at prices in every case above those quoted last week. Large transactions, too, have taken place in Russian produce. The change in the weather has checked the upward tendency of the market; but, whatever the season may now be, a return to former prices is now impossible. Yarns have been in brisk demand. In most cases spinners have been able to obtain some advance in prices. They are, however, by no means eager to commit themselves to important contracts for long forward delivery, the outlook being yet uncertain. The general impression is that prices will go higher. Jute yarns have shared in the activity of the last week, and prices have become very firm.

THE IRON MARKET.—The iron market preserves the even tenor of its way. There is no speculation, and nothing that can be described as animation; but fresh orders to hand are numerous if not large, and manufacturers are without difficulty able to maintain their prices. The Northern Railway Company are purchasing Vignoles rails, 12 metres in length, and weighing 43 kilo. per metre. Several miles of line have been laid with these rails, with highly satisfactory results. The "way" possesses greater stability, and jolting is much lessened.

AMSTERDAM, 12TH JUNE, 1888.

THE MAILS.—In connection with the popular route between England and the Continent, *viâ* Queenboro' and Flushing, negotiations have taken place between the German and Dutch Governments, as far as the mail trains are concerned which run between Germany and the Dutch port. Hitherto the route chosen was by Boxtel and Wesel. The German authorities do not consider this the most direct and best, and have therefore suggested another route, *viâ* Crefeld and Venlo. The Dutch Government did not agree to this, and dispatched two delegates to Berlin, in order to negotiate with Herr Stephan, the German Postmaster-General. They do not seem to have entirely succeeded, for it is announced that the German Government is only willing to continue the use of the route *viâ* Boxtel and Wesel for North Germany, particularly Hamburg and Bremen; but for Berlin and Central Germany Herr Stephan insists upon the route by Crefeld and Venlo.

MADRID, 11TH JUNE, 1888.

THE BARCELONA EXHIBITION.—Notwithstanding the fact that the Exhibition has been formally opened by the Queen, it is still in an incomplete state. During the hottest of the summer months it will be closed, and will be re-opened again in September. By that time there will be some novelties of general interest representative of Catalan industries.

IRON ORE.—Stocks of iron ore are accumulating at Carthagena, shipments having been smaller than the quantities raised, and complaints as to the state of business are being heard in consequence.

IRON WORKS.—The iron works at Beasain, which include two charcoal blast furnaces and a Siemens-Martin furnace, are for sale. The owners have found it advisable to transfer their plant for the manufacture of tin plates and for general purposes to Bilbao; but the works are very suitable for making the best pig iron for special steel, and for mitis castings.

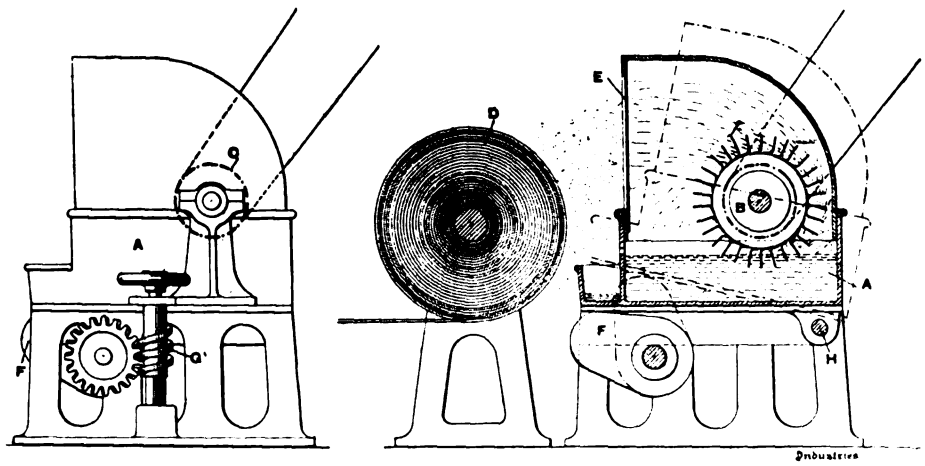
ELECTRIC LIGHTING.—Some theatre proprietors, whose arrangements are not sufficiently far advanced to allow of their installing the electric light by next September, as required by the present regulations, have agreed to petition the Government for an extension of time. In the meantime two of their number have been deputed to visit France and England, to inquire into the best system to be adopted; but as they are not technical men, the probabilities are that they will return about as wise as they were when they started. The Gülcher Company are going to light part of Madrid, the installation being one of about 4000 lights. It is quite clear that a large central station of 20,000 to 30,000 lights would be a profitable speculation in Madrid, as the light could be sold at a high price. The mistake made by those who took the matter up was in aiming at making a profit on erecting the installation instead of on supplying the light.

NEW YORK, 2ND JUNE, 1888.

THE COAL MARKET.—The anthracite coal market shows a better tone than it has done for some time past, but the quantity of business is no greater. Individual operators who have been doing the heaviest cutting in prices have in some cases advanced their rates a little, having taken orders which will keep them employed for some time, and being in consequence more independent. Bituminous coal is still dull, but the market is nearly sold out. There are a few large buyers who are still waiting for lower prices, but this is not likely to occur.

THE IRON MARKET.—The principal topic of interest to the iron trade has been the reduction made by the Thomas Iron Company, and there is no doubt that there will be a re-adjustment of prices all around. Until this is done trading will be limited to the small lots of iron required for immediate use. Prices of pig iron are all lower, but sellers are not generally inclined to meet the Thomas Company's prices. Good No. 1 foundry iron cannot now be bought in the market at less than $19 per ton, and the Thomas Company will only sell to their own customers at $18. The market is still a waiting one, and it is by no means certain that competition is at an end. A month ago the iron masters told the railroad managers that they must have lower rates or shut down, and having been granted part of the reduction asked for, they have now reduced the price of iron, hoping that that will increase the demand; with regard to manufactured iron a decided improvement is noticeable in the number of inquiries, and in the case of a few leading mills a moderate addition has been made to the orders in hand. Prices are very low, however, and give no indication of improving; but with fuller employment and cheaper material manufacturers are disposed to think that the worst is over. Some very large orders have been taken within the past week, and it is understood that other contracts are only waiting the completion of financial arrangements, which, with the present easy money market, ought to be easily done. The general market rates are about 1·8c. to 1·9c. per lb. for bars, and 2·0c. to 2·1c. for plates and angles; but special rates can be obtained for large orders. There has been no new business in steel rails, but prices remain at $31 to $31·50 per ton at the mill.

THE METAL MARKET.—The most noteworthy thing in the copper market has been the pool sale to consumers. Though nominally made by the combination of mining companies, it was practically made by the syndicate. The sale amounted to about £9,000,000, and covered deliveries for June, July, and August, at 16½c. per lb. Instead of selling to customers in a body, as has heretofore been done, contracts have been made with individual consumers, who are not allowed to part with more than a small quantity of their purchases, and that only at ¼c. above the price paid by them. There has been little inclination to speculate in near deliveries, but some sales have been made for January delivery at 16c. The tin market at the beginning of the week was dull; but the situation is becoming stronger, as the stocks of dealers and consumers are getting very low. Closing quotations are at 21½c. per lb. for spot. There has been a little more business in lead, sales amounting to about 300 tons at prices as low as 3·95c. per lb. The price is likely to decline during the coming summer months, and consumers are looking for it to reach 3½c.



ELECTRIC LIGHTING.—The Westinghouse Electric Company are engaged in making experiments to obtain data regarding the long distance distribution of electric lighting on their system. A number of lights were put up at a distance of four miles from the dynamo, and as a result of their trial several changes were found necessary in the methods used. The firm is now erecting two plants, one at Bernardino and the other at Riverside, California.

THE PHONOGRAPH.—The Edison Phonograph Company has been incorporated at Newark, New Jersey, with a capital of £60,000. It is stated that the factory at Bloomfield, N.J., is turning out phonographs at the rate of twenty per day, and unless something unexpected occurs the first order will be filled by the middle of June or sooner. The price of the commercial phonograph, which Mr. Edison expects will take the place of the short hand clerk, is £17.

THE DISTILLATION OF SEA WATER.—The Government is fitting a distilling apparatus in many of the new ships, which has several features to recommend it. It has been necessary heretofore to have a donkey boiler, or to set one main boiler aside for use in distilling, and either plan has its inconveniences. As steam will be used constantly in the new ships for power purposes, with the new arrangement, the same boiler can also be used for making fresh water without the oily unpleasantness that usually accompanies distilled water made from a boiler fed from a surface condenser. Steam from a special boiler is led through a series of coils, which are contained in a vessel supplied with sea water. The steam is condensed, or partly so, and falls into the condenser. A portion of the sea water is evaporated and is carried into a second coil in which it is also condensed, and this water is of excellent quality. The first vessel is fitted with blow-off and brine cocks, and occupies very much less floor space than a donkey boiler of the necessary capacity would do. A test made with one of these arrangements, having 52 sq. ft. heating surface in the evaporator, maintained a pressure of 51lb., and had a capacity of 900 gallons of water per day.

BREADNER'S COPPER DAMPING BRUSH.

BREADNER'S COPPER DAMPING BRUSH.

THE above illustrations show an improved copper damping brush, introduced by Mr. E. Breadner, Ogden's Chambers, 134, Deansgate, Manchester, which has been designed with a view to furnish paper makers, calico printers, and bleachers with an apparatus for thoroughly and evenly damping materials. As will be seen from the illustrations, the machine consists of a tank A, in which a roller B is revolved by means of a belt on the pulley C. The roller B is provided with a great number—about 14,000—brush points, which take the water from the tank A and throw it against a sheet of wire gauze E, thereby producing a fine and evenly distributed spray, which damps the roll D of the material under operation. The tank A is pivoted at H, and may be raised into the position indicated by the dotted lines by means of a cam F, which is actuated by the worm G and a worm wheel. By thus raising or lowering A a finer or coarser spray is accordingly produced. The advantages claimed for this machine are, that the damping is done more thoroughly and more evenly than with the apparatus now in use, and that the copper brush does not wear to the same extent as fibre or bristle brushes, which, when worn, distribute the water unevenly, besides being a source of constant trouble and expense.

EMERY TESTING MACHINE.*

ALMOST from the commencement of modern engineering practice, the need has been recognised of obtaining accurate knowledge of the strength of materials as a basis for all work of design and construction; and the earlier engineers addressed themselves to this object with an earnestness and intelligence which will always command admiration, especially in view of the fact that the circumstances of their times required all such work to be done at their own expense, and usually with their own hands and heads. The ability which they brought to bear upon it, and the thoroughness with which it was accomplished, are best evidenced by the fact that the determinations of Tredgold, Buchanan, Rennie, and many others, were accepted by the engineering profession at large for more than half a century, and have only recently been superseded by the more accurate and extensive determinations of later investigators, assisted by modern appliances, and often aided materially by governmental support. Nearly all the earlier determinations of the strength of metals, whether made by the older authorities above named, or by the succeeding group, represented by Fairbairn, Stephenson, Clark, Kirkaldy, and many others, were based upon small specimens, of which the greatest transverse dimension rarely exceeded 1in. The co-efficients determined from these small specimens were for a long time accepted as a true index of the resistance per unit of section in all structural members composed of the same material, whether of large or small size. In recent years, however, engineers have had forced upon their attention the fact that material produced and used in large masses does not generally possess the same physical qualities as in the smaller and carefully prepared forms that were usually adopted in making the earlier experimental investigations. All doubts on this point were speedily dispelled, as soon as testing appliances were provided, however crude, of capacity sufficient to test specimens of even the smallest sizes usually employed in engineering construction. As a result the present tendency is towards the multiplication of testing machines, for enabling every large engineering works to test the whole of its important material; and is still more markedly in the direction of employing machines of such capacity and strength as to enable material of all kinds and of nearly all dimensions used in practice to be tested up to the point of deformation or destruction. In the United States, the importance of this matter was early recognised and discussed, with the result that in 1875 a committee was appointed by Congress for the special object of conducting investigations in regard to the strength of materials, and funds were appropriated for the purpose. This body, which became known as the United States Board for Testing Iron, Steel, and Other Materials, entered upon their work in 1875, and during that and the succeeding three or four years made a great number of experimental investigations, which were subsequently published by the United States Government, and have been of great value. One of the most important actions of the Board, and the one which probably constitutes their chief monument, was the acquisition of the 400-ton (American ton of 2000lb., 400 tons American = 357 tons English) testing machine erected at the United States Arsenal at Watertown, Massachusetts, and still situated there. From the commencement of their work, the Board recognised the importance of securing a testing machine possessing a degree of accuracy far greater than had previously been attained, and enabling it to be justly ranked as an instrument of precision. A machine of 800,000lb. or 357 tons capacity, was accordingly ordered from Mr. A. H. Emery, of New York, which was guaranteed by the maker to possess the stipulated qualities of precision, endurance, and general adaptability to the work. The machine was completed and put into use in 1879, since which year it has been in constant service, having tested up to the present time more than 15,000 specimens, of dimensions varying throughout the entire range of its capacity. It was subjected originally to a test load of 1,000,000lb., or 25 per cent. beyond its intended limit. The largest section of wrought iron that has been broken in it had a diameter of 5·04in., or an area of 20 sq. in. The machine will test in tension specimens up to 28ft. long by 30in. wide, and in compression columns up to 30ft. long. Its sensitiveness is such as to show distinctly on the indicator a force of only one pound applied to the specimen. During all its years of constant service it has maintained unimpaired its efficiency, accuracy, and sensitiveness, and is to-day as perfect in its action as when first erected: its mechanism is remarkable as well for originality as for perfection. During the past five years the construction of testing machines on the Emery system has been regularly carried on in the works of the Yale and Towne Manufacturing Company, Stamford, Connecticut, under the direction of the writer, where numerous machines have been built of various dimensions and capacities adapted to the requirements of commercial work. It is therefore believed that a description of one of these machines, including what is novel and worthy of remark in its details, will not be without interest to English engineers. The designs selected for description are those for a vertical testing machine of 300,000lb., or 133 English tons capacity, two of which have already been built and have proved exceptionally excellent in actual service. The illustrations given hereafter clearly show the construction of this machine.

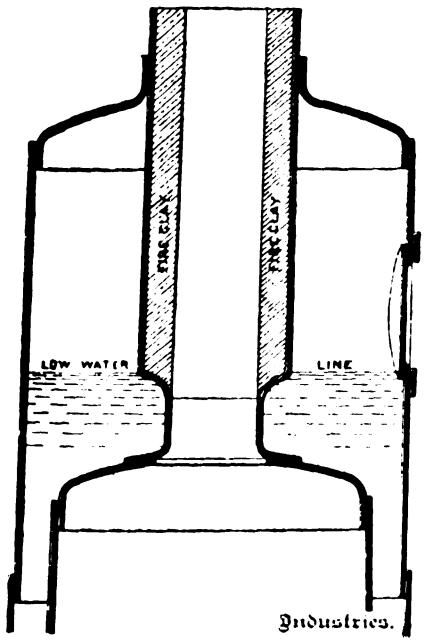
Principles of the Emery Machine.—In the broad principles of construction on which the Emery system of testing and weighing machinery rests are included two radically new and highly important elements, viz.: (1) An arrangement of hydraulic chambers and diaphragms, capable of receiving without injury pressures and shocks of great intensity, and of transmitting these simultaneously, without loss from friction, to a convenient point for the purpose of measuring and recording them; and capable also of reducing them to such lower term or degree as may be desirable. (2) A means for flexibly uniting a vibrating scale beam either to a fixed abutment or to another beam of the same system, in such manner as absolutely to eliminate friction, and to preserve indefinitely the fulcrum intervals or distances precisely as first adjusted, and to resist and transmit all the pressures and shocks to which the fulcrums are subjected, without in the slightest degree impairing their sensitiveness or durability.

Hydraulic Chambers.—The hydraulic construction is such that through it the load or strain put on the specimen is transmitted without loss to a hydraulic chamber or "support," in which is confined a thin film of liquid, usually 0·015in. in thickness, the plane of which is normal to the axis of the machine and to the direction of strain. The area of this film is such that the maximum strain applied to the specimen, and through it to the hydraulic support, shall not be more than can be borne with safety in its most exposed part by the thin diaphragm which seals the chamber. There may be several of these supporting chambers, as in the case of the Watertown machine, where the load is received upon four such supports; or there may be only one, as in the case of the machine now to be described. The pressure per square inch on the liquid within the hydraulic support is transmitted through a small copper tube, without loss from friction or otherwise, to a much smaller chamber or "reducer," containing a similar thin film of liquid. The acting area of the liquid in the reducer is less than that in the larger chamber or support, in the proportion in which the load on the specimen is desired to be reduced before it is received upon the beams in the scale case where it is measured or weighed. In the present machine this reduction is as 30 to 1. The maximum load of 300,000lb. on the large support is thus reduced to a maximum of 10,000lb. on the reducer; and this latter strain is all that is transmitted to the beams in the scale case. The elastic resistance to bending of the sealing diaphragm in the hydraulic support causes a slight reduction of the pressure transmitted to the liquid under the sealing diaphragm of the reducer. As the diaphragms, however, are of very thin sheet brass, usually not more than 0·005in. thick, and as the maximum motion of the piston of the support is less than 0·001in. while the free span of the diaphragm is 0·10in., this reduction in pressure is very slight, and is practically immaterial, for the reason that it is fully taken account of in the adjustment of the weighing mechanism.

Levers.—In the scale case containing the weighing mechanism, the pressure transmitted from the reducer is received at one end of a system of levers, and is accurately measured by means of devices described later on. It is first received upon a single lever having a ratio of 20 to 1, whereby one-twentieth of the pressure is transmitted to a second lever, from which is suspended a series of poise rods arranged to carry the balancing weights for weighing the load. This second lever, having a ratio of 25 to 1, is also connected to a third lever or indicator bar, the arms of which are as 40 to 1. The motion of the point of the indicator bar is consequently 20,000 times that of the reducer piston, and therefore 600,000 times that of the piston in the main support, which is directly connected with the specimen under test. As the force required to move any one of the poise weights for showing a change of balance will vary directly as the square of the velocity of its movement, it follows that, since the poise weights move only one-fortieth as much as the indicator, their resistance to the movement required by the indicator for showing a change of balance is only $\frac{1}{1600}$th part of what it would be, if, as in other scales, the same extent of movement had to be made by the very lever carrying the weights. A movement of one six-millionth of an inch at the specimen produces a motion at the indicator point of one-tenth of an inch, which is easily visible; and being resisted by no friction, and having only so slight a resistance of inertia from the poise weights, the indicator shows clearly any slight or sudden change in the balance of the scale. It thus enables the exact point to be detected at which the load falls off slightly, as in the case of a tension specimen when a strain is reached which gives it a slight permanent set; the sudden change in the balance of the machine, shown by the vibration of the indicator, at once denotes the point at which the limit of elasticity in the specimen is reached. This is due to the fact that a slight reduction in the strain always occurs at that point, owing to the sudden elongation of the specimen, which is practically instantaneous, while the movement of the straining press for taking up this slack requires a sensible length of time.

Fulcrum Plates.—Each of the supporting and connecting fulcrums in the system of levers consists of a thin plate of tempered steel, and acts absolutely without friction or back lash. Each fulcrum plate offers a slight elastic resistance to bending, but this resistance is recognised and fully balanced in the adjustment of the poise weights; in other words, if this and the other elastic resistances of the mechanism amounted to one-thousandth part of the load, the poise weights would then need to be one-thousandth part lighter than if the mechanism offered no such resistance. The poise rods which carry the balancing weights are also suspended by thin steel plates, which give no frictional resistance. In common scales there is unavoidably a large frictional resistance, whereby more or less of the pressure transmitted by the load is absorbed, and thus fails to reach the balancing weights. This defect is magnified by the tendency of the frictional resistance, first to hold the balancing bar from moving forward until the pressure has accumulated somewhat; and then, after it has moved forward under this impulse and has been carried too far, to hold it in that advanced position and not allow it to recede and come to rest at the true point corresponding with the load. The Emery system of construction is such that none of these frictional resistances occur. Certain elastic resistances are developed at various points, but these are all duly considered in adjusting the poise weights as above stated. The distinction may be briefly stated thus: Frictional resistance and elastic resistance both absorb power, but the former absorbs it finally, whereas the latter simply stores it up and subsequently gives back whatever power or impulse it has received. This difference is one of great importance in any mechanism for weighing. The thickness of the fulcrum plates varies from 0·004in. to 0·06in. When they are 0·01in. thick or more, they are used in compression; but when of less thickness, they are usually employed in tension. When used in compression, they are held by being forced, under pressures generally of 60,000lb. to 120,000lb. per square inch of section, into grooves planed or sawn in the pieces they are to unite; when used in tension, they are generally clamped in position. The maximum working strains on the fulcrum plates, whether in tension or in compression, are usually limited to 50,000lb. per square inch. The exposed or free portion of each fulcrum plate varies in length from 0·1in. to 0·2in., this being the interval separating the two parts that are connected by the plate. The angular motion of the lever causes a bending of the fulcrum plate which carries it; but this bending is very minute, except only in the case of the fulcrum plates carrying the last lever or indicator, and these are thin and long. The resistance of the fulcrum plates to bending is very considerable, but is always well within the elastic limit of the material; so that their resistance is entirely elastic, and not frictional, and is provided for as above explained. The above devices, whereby pressures of high intensity are received, transmitted, rendered visible, and measured, are made available for their intended purposes by means of other details, equally novel and important, whereby the parts that receive and transmit the load are securely held against displacement or derangement in any direction save only one, which is parallel to the true line or axis of strain: in which direction they are left entirely free to move, without friction of any kind, and without any resistances except such as are taken account of in the total resistance of the weighing mechanism.

(To be continued.)



* Paper read by Mr. Henry R. Towne, of Stamford, Connecticut, U.S.A., before the Institution of Mechanical Engineers, on the 3rd ult.

SOME RECENT OFFICIAL REPORTS ON BOILER EXPLOSIONS.

Report No. 258 refers to the explosion of a small vertical boiler, 2ft. 8in. diam., on board the trawl boat "Pioneer," about 57 tons register, which occurred at 11-40 p.m. on the 5th January, while under sail in Botany Gut, in the North Sea. The boat was owned by Messrs. Morgan Brothers, Gorleston. This explosion is precisely similar in character to that which is reported to have occurred on board the "Pilot," and described recently, but more serious in its character and results, the skipper being severely scalded. The uptake above the water line was corroded so much that it partially collapsed at the ordinary working pressure, although only 8in. diam. and originally $\frac{3}{16}$in. thick, rupturing the plate and allowing the steam to escape through the fire hole door. The Engineer Inspector observes that "the conditions under which these boilers (of trawl boats) are worked render it most desirable that frequent examinations of them should be made by a competent person. When subjected to similar treatment to that received by this boiler, where steam was raised and the pressure allowed to fall at least twice daily, it must be expected that parts subject to the action of the fire will soon decay."

There is no doubt that had this uptake been examined by a competent person its dangerous condition could not have escaped notice; and the necessity for examination, not only of these but any other steam boilers, is generally admitted. But the concluding portion of the Engineer Inspector's remarks is not quite so clear, and no suggestion is offered for the prevention of similar accidents in future. The rapid deterioration of plates exposed to the action of fire on one side, and steam on the other, has long been known, and the effect can easily be provided against in the case of vertical fire box boilers, by the simple device of protecting the uptake by a fire clay, or, if sufficiently large to admit it, fire brick lining; or in the case of boilers already made, by the introduction of a cast iron sleeve or lining of $\frac{3}{4}$in. to 1in. thick. If the uptake of such boilers were constructed as shown in the sketch below, accidents arising from unequal and special corrosion in this part would be prevented; the uptakes would also be protected from the chronic state of over-heating to which they are subject, grooving of the flanges, crown of the shell, or top of fire box—according to mode of construction—would also be obviated, and the safety of the boiler greatly increased.

Report No. 259 describes the explosion of a small saddle boiler, such as is usually adopted in hot water circulating arrangements, at the smithy of Mr. W. Thomson, Alloway, near Ayr. The boiler was 5ft. 4in. long, 3ft. 4in. wide, curved to a radius of 2ft. 6in., and about 15in. deep. It was not provided with any stays, and it had been made of $\frac{3}{8}$in. plate, about twenty-five years ago, and used for heating purposes at the Ayr county prison, but removed and sold to Mr. Thomson for £2. 5s. about eighteen months before the explosion. Despite its age, no particular defects were discovered in the boiler by the Engineer Inspector, and the explosion, which resulted in the slight injury of five persons, was due to working the boiler at a pressure for which it was never intended.

On the 13th inst. the Town Council of Brighton decided to retain the electric railway.

Great Northern Telegraph Company.—Traffic Returns.—Receipts in May, 1888, £23,200; 1st January to 31st May, 1888, £108,400; corresponding months, 1887, £103,520; corresponding months, 1886, £100,960.

Notices of Meetings.

NEXT WEEK.

Society of Architects.—Tuesday, 19th June, 7 p.m. Fifth annual general meeting.

Royal Meteorological Society.—Wednesday, 20th June, 7 p.m. Papers to be read: "First Report of the Thunderstorm Committee; On the Photographs of Lightning Flashes," drawn up by the Hon. Ralph Abercromby, F.R.Met.Soc.; "The Cold Period from September, 1887, to May, 1888," by Charles Harding, F.R.Met.Soc.; and "Observations on Cloud Movements near the Equator, and on the general character of the Weather in the Doldrums," by the Hon. Ralph Abercromby, F.R.Met.Soc.

Royal United Service Institution.—Friday, 22nd June, 3 p.m. Paper to be read on "Fire Discipline and the Supply of Ammunition in the Field as provided for by Foreign Powers," by Captain W. H. James, F.G.S.

PRICES CURRENT, 14th June.

Do. at Hull (on quay)	5/-

Messrs. Carrick & Brockbank, Manchester, report as follows:—

Copper.—Quotations for Chilli gobs have been steady during the past week. Spot parcels £82. 10s. to £83 per ton; three months, £79 to £79. 10s. per ton. The market is kept steady by the operations of the syndicate. The consumptive demand continues to be very light, and the copper trade generally is without life.

Tin.—Straits sharp cash parcels are fully £3 per ton lower since our last, quotations are £80. 10s. to £80. 15s. per ton. English is also lower, £89 to £90 per ton; there is a fair business doing at the above prices.

Lead.—Steady. Spanish, £12. 5s. to £12. 7s. 6d. per ton.

Spelter.—Quiet, at £16 to £16. 5s. for warrants.

SHIPBUILDING NOTES.

The screw steamer "Spindrift," built by Messrs. Russell and Co., Greenock, and engined by Messrs. Dunsmuir and Jackson, of Govan, was recently subjected to an official trial. The "Spindrift," which is of 3500 tons gross register, has been built under the superintendence of Mr. David Pollock, consulting naval architect, and will form an important addition to the fleet of the China and Japan Shippers Union.

On Saturday, the 9th inst., Messrs. Wm. Doxford & Sons, Pallion, launched the screw steamer "Callisto," which was built to the order of Messrs. Pinkney, Sons, & Clare, of London. Her dimensions are 250ft. by 36ft. by 18¼ft., and she carries 2400 tons dead weight all told. The triple expansion engines were built by the same firm, with cylinders 18in., 29in., 48in., by 33in. stroke. She is built of steel, with all the latest improvements, including lap jointing of the shell under water. The "Callisto" has been sold by Messrs. Pinkney, Sons, & Clare to Messrs. Hudig and Veder, of Rotterdam.

On Saturday, the 9th inst., the steamer "Henry," of Liverpool, 1550 tons dead weight capacity, was taken out for her trial trip. The vessel belongs to Messrs. Curwen Brothers, of Liverpool, who contracted at the beginning of the year with Messrs. Westgarth, English, & Co., of Middlesbrough, to fit her with completely new triple expansion engines. Considerable improvements and alterations to the ship have been carried out by Messrs. R. Craggs & Sons, of Middlesbrough, and both the ship and engine work has been done under the superintendence of Mr. W. C. Lang, of Liverpool. The engines have cylinders 15in. by 23½in., and 39in. by 33in. stroke, and throughout the day their work gave entire satisfaction to the owner and engineers on board. The vessel was in ballast trim, and made a speed of 10¾ knots.

The s.s. "Zancla," one of the Mediterranean fleet of Messrs. John Glynn & Son, went for her official trial trip last Saturday, the 9th inst., after having had her engines converted from the ordinary compound to the triple expansion type. The high pressure cylinder is 19in., the intermediate 30in., and the low pressure 49in. in diameter, each having a stroke of 33in. The boiler is of steel, 15ft. 3in. diam. by 10ft. long, fitted with four of Brown's patent ribbed furnaces, 3ft. 2in. internal diameter. With a steam pressure of 150lb. per square inch, and seventy-eight revolutions per minute, 770 h.p. was indicated, the vessel attaining a speed of 11½ knots per hour. The whole of the work of conversion has been executed by Messrs. D. Rollo & Sons, of Liverpool, under the superintendence of Mr. S. Hepburn, the company's consulting engineer.

HOME INDUSTRIES.

MANCHESTER, 14th June, 1888.

The Ribble Scheme.—At a special meeting of the Preston Town Council, held on the 7th inst., the report of Mr. James Abernethy, C.E., on the present condition of the Ribble works, was presented and read. The report first dealt with the variations of the works which were authorised by the Act of 1883. These were principally the enlargement of the dock area from 30 to 40 acres, the lengthening of the lock 50ft., the provision of a greater depth on the sill of 2ft. 6in., which gave 23ft. 6in. of water in neap tides, the construction of an entrance dock and a timber pond, and the dredging and deepening of the river as far as Lytham. Mr. Abernethy disapproves of the enlargement of the dock, and expresses the opinion that the lock should be widened as well as lengthened. He also recommends the construction of an invert to the lock instead of a thin layer of concrete only being placed on the sandstone rock. The next subject referred to in the report was the formation of a channel to the sea. Beyond Lytham, where the dredging is to end, there are a range of sandbanks six miles wide and seven miles long, which are exposed to the full force of the westerly winds. Mr. Abernethy therefore recommends that the channel seven miles in length beyond Lytham should be formed, not through the shifting sands, but along the north or shore channel. This channel would be protected seaward by the Salthouse Bank, which is in some parts 18ft. above the level of low water, and would have a hard foreshore as its landward bank. This work, it is estimated, would take four years to carry out, and an approximate expenditure of £300,000 would be incurred in addition to the cost of dredging at present contracted for. No discussion of the report took place; but it is already quite clear that the works sanctioned in the last Act will for the present be suspended.

The Engineering Trade.—The condition of business amongst stationary engine builders still continues to be satisfactory, and in some cases a higher price is being obtained than has previously been possible. There are better reports on all sides, and it is scarcely probable that there will be any lack of work during the present year. Millwrights, boiler makers, and locomotive builders are better off for work, although the improvement in the condition of the last mentioned is not very noticeable as yet. Machine tool makers are gradually filling their order books, and are in a more satisfactory condition than for some months past. A good many special tools are being made, and even where ordinary types are used changes in details are frequent. Messrs. James Spencer and Co., of Hollinwood, have considerable orders on hand for the Indian States Railways, and are also constructing a special plant for making finished nuts for Messrs. S. Marsden & Co. Messrs. Hetherington & Co. have a planing machine in hand for planing steel plates for bridge work, the bed being over 50ft. long, and also a special machine for milling up the ends of girders instead of chipping them. The latter machine can be used for ending up a number of plates together if so desired. The same firm are constructing two wheel lathes with 9ft. face plates. Machine makers are all well sold, and are extremely busy generally. Carding engines of the modern type are largely ordered, and improvements of their details continue to be made. Messrs. Ashworth Brothers have recently adopted a plan by which the pull of the belt is received by the boss of the pedestal on which the driving pulley revolves, and the cylinder is driven by means similar to those employed to revolve a shaft in the lathe. This improvement is intended to prevent forward wear in the cylinder bearings. Mr. Thomas Knowles, of Bolton, has patented an improved method of sustaining the flats during the grinding of the wire, by which the "heel" is accurately maintained, and Mr. John Tatham is making the apparatus. Loom makers are not obtaining fresh orders at the rate they would desire, and are not in quite such a good condition as they were. Constructional iron work is in poor demand, and generally speaking iron founders are in a very bad condition. Electrical engineers are busy generally, and the same may be said of gas engineers. The West Gas Improvement Company, Limited, are busily engaged in the construction of machines for charging the retorts of gas works.

Cotton Trade Wages.—The Bolton cotton spinners have decided to grant an advance of 5 per cent. in the wages of operative spinners and card room hands, and 10 per cent. to strippers and grinders and blowing room hands. This decision affects 30,000 workpeople. The loomers and drawers in Blackburn have resumed work on the understanding that an increased price be paid on certain classes of goods, and that the remainder be subject to an arrangement to be made by a joint committee of the employers and operatives.

LONDON, 14th June, 1888.

The Money Market.—But for the requirements of the Stock Exchange for account purposes, the money market would have been duller than ever this week. The lowering of the Bank rate last week was followed at once by a corresponding drop in other rates, which are now almost as low as they can possibly be. The stock markets are dull, and devoid of tone. Home railway stocks are fairly healthy; but the dividend anticipations are not particularly hopeful, and with the exception of Great Westerns, and a few others, they are not being extensively bought. The recent new loan issues have called attention to Colonial stocks; the older issues are cheap in comparison with the new ones, and hence there has been some buying. The American market is very lifeless, and there is no support from New York at all. Mining shares do not offer a very hopeful channel for investment, and the course of prices in the principal speculative departments of this market is so singular as to puzzle the most acute. A breakdown in copper is expected, but the French syndicate seems to be still confident. There has been a remarkable collapse in diamond shares.

Companies.—The following new companies have been registered since our last report: Tulladega Iron and Steel Company, Ld., with a capital of £100,000, to carry on business as iron masters, &c., at Alabama, U.S.A.; The International Cotton Seed Cleaning Company, Ld., with a capital of £75,000; The Wimbledon District Brick and Tile and Pottery Manufacturing Company, Ld., with a capital of £50,000; Joseph Ashforth & Co., Ld., with a capital of £50,000, to carry on business at the Bruce Works, Sheffield, as manufacturers of steel, files, nuts, bolts, tools, &c.; The Austro-Hungarian Petroleum Company, Ld., with a capital of £16,320; The Santa Fé and Cordova Great Southern Railway Construction Company, Ld. (Argentine Republic), with a capital of £500,000; Fleming's Oil and Chemical Company, Limited, with a capital of £50,000; The Highfield Tanning Company, Limited, with a capital of £30,000; The Anglo-Indian Fibre Company, Ld., with a capital of £25,000; The Manchester Patent Box Company, Ld., with a capital of £50,000; The Wood Top Loom and Power Company, Ld., with a capital of £20,000; B. Vickerman and Co., Ld., with a capital of £200,000, to carry on business as woollen manufacturers; W. T. Beesley & Co., Ld., with a capital of £40,000, to purchase rolling and wire mills in Sheffield and Rotherham; The Coventry Machinists, Ld., with a capital of £100,000; The Zuid Afrikaansche van Outplofbare Stoffen Company, Ld., with a capital of £84,000, to manufacture gunpowder, dynamite, &c.; The Petroleum Engine Company of America, Ld., with a capital of £150,000, to acquire the patents for the United States of the Priestman Petroleum Engine—a description of which appeared in our issue of the 18th ult.; The Taquah and Abosso Gold Mining Company, Ld. (Gold Coast), with a capital of £100,000; The Douglas Head Mining Company, Ld. (Isle of Man), with a capital of £20,000; The Venezuelan Mines, Ld., with a capital of £2,000,000; The Roman Gold Mines, Ld., with a capital of £200,000; The Golden Chance Mining Company, Ld., with a capital of £400,000; The Orense Tin Mining and Smelting Company, Ld. (Spain), with a capital of £250,000; and The Swan River Gold and Silver Mines, Ld., with a capital of £200,000. The total capital of the companies registered during May amounted to £84,749,644.

Railways—The gross receipts of the twenty-three principal railways in the United Kingdom, for the week ending 3rd June, amounted to £1,235,847 on 15,861¼ miles, as compared with £1,322,257 in the corresponding period of 1887, when the mileage was 15,741 miles. An increase is thus shown in the mileage of 120¼ miles or 0·7 per cent., and a decrease in the receipts of £86,410 or 6·5 per cent. This decrease is due to an ordinary week's traffic being compared with a week which included part of the Whitsuntide traffic of last year.

The Navy.—The keel plates of two new war vessels, the "Barrosa" and the "Beagle," have been laid down at Portsmouth. The former is a protected cruiser 220ft. long, 35ft. broad, and with a mean load draught of 14ft. She is of the "Blanche" class. The "Beagle," which is of the "Buzzard" type, will be 195ft. long, 30ft. broad, and with a mean draught of 12ft. 5in. A new set of boilers is to be provided for the coast defence vessel, the "Glatton." Orders have been received at Sheerness dockyard to prepare for building the "Barracouta," a cruiser of a new type designed by Mr. W. H. White. She will be 233ft. long, 35ft. wide, and have a displacement of 1580 tons, and is to have triple expansion engines of 3000 i.h.p. Four ships of this class are to be laid down. Two other vessels of a somewhat similar type, the "Barham" and the "Bellona," are also included in this year's building programme. The new twin-screw composite sloop "Daphne" has been launched at Sheerness Dockyard. Her length is 195ft. between perpendiculars and 212ft. over all, with a breadth of 30ft., and a displacement of 1090 tons. The Greenock Foundry Company will supply the engines, which, when working under forced draught, are to develop 2000 i.h.p., and to propel the ship at the rate of 14½ knots. The total cost of the "Daphne," when completed for sea, is estimated at £63,087. The twin screw second class cruiser "Medea" was launched at Chatham on Saturday last. She has a steel turtle back deck, 2in. thick in the sloping parts, and 1in. in the horizontal parts. She is 265ft. long over all, 42ft. beam, with 23ft. depth of hold. The engines, which are by Messrs. Humphreys, Tennant, & Co., of Deptford, are triple expansion of 9000 h.p., with horizontal cylinders, 34½in., 51in., and 76½in. respectively, and 3ft. stroke. The vessel is intended to have a speed of 20 knots.

Parliamentary.—The Electric Lighting Act (1882) Amendment Bill has passed through Committee in the House of Commons.—The first meeting of the Standing Committee on Trade was held on Monday last, the Bill remitted for their consideration being the Railway and Canal Traffic Bill.

The International Geological Congress.—The next meeting of this Congress, which assembles once in about three years, will be opened in London on the 17th September next. So far, 395 geologists have intimated their intention of being present, 210 of these being British, and 185 foreign; whilst the number of countries represented will be twenty-two, so that the meeting will be the largest yet held. Professor Huxley will be the honorary president, and Professor Prestwich the president.

The British Association.—The fifty-eighth annual meeting of this Association will begin at Bath on Wednesday, 5th September, under the presidency of Sir Frederick Bramwell.

GLASGOW, 14th June, 1888.

Pig Iron.—There has been considerable movement in the local pig iron market. English iron is held in this market with some firmness. Shipments for last week were fairly brisk. The leading items in the return show considerable advances, although as far as Italy and the United States are concerned there is room for much improvement before the figures of last year are reached. Last week, however, the shipments abroad were generally increased; the United States, Canada, and Australia took large quantities, while the shipments coastwise increased from 2000 tons to 4856 tons for the week.

Institution of Naval Architects.—The summer meeting of the Institution of Naval Architects will be held in Glasgow, on the 24th July and the three following days. A large and influential local committee has been formed, under the secretaryship of Mr. W. J. Miller, who is the secretary of the Institution of Engineers and Shipbuilders in Scotland.

Local Taxation.—An important increase in local taxation has just been decided upon. The School Board of Glasgow have found themselves with an income of £158,866 face to face with a deficit of nearly £10,000. The Board has therefore resolved to increase the school rate from 6¾d. per £1 of rental to 7¾d. per £1. This additional 1d. per £1 on the rental of Glasgow means an addition of £12,000 a year to the amount raised in taxation.

The Exhibition.—In spite of extremely unfavourable weather, the Exhibition is still keeping up a high average attendance. On Monday last, the thirtieth day during which the show has been open, the total number of visitors, including attendants, reached the total of 1,006,221. The average daily attendance during the period was 33,540. On Saturday, though the weather was unfavourable, the presence of a large number of excursionists brought up the number to 50,615.

(From our own Correspondents.)

LIVERPOOL, 13th June, 1888.

The Timber Trade.—There has been very little improvement in the trade of this port during the last month, and any slight rise in prices has not been permanent. The new period of imports of Quebec pine has now commenced, and there is now a stock of about 108,000 cub. ft. of waney and square on hand. The 1000ft. of St. John wood which was in stock last month has not been sold. The consumption of N. B. and N. S. spruce deals has been in excess of the imports, and the stock is consequently very low; the sales have all been by private treaty. The small stock of red pine has not been altered since last month, there having been no fresh imports, and practically no consumption. The stock of oak on hand now is only 62,000 cub. ft., the consumption having been 40,000 cub. ft., or nearly double the amount in the corresponding month of last year. 15,000 cub. ft. of oak were imported last month by steamer from the United States. There has been a fair import and consumption of oak planks, the stock now amounting to 191,000 cub. ft., or nearly four times the amount held this time last year. The prices of first class planks have fallen considerably, and cannot well improve unless there is a restricted import. The fresh imports of elm have not yet commenced, but there is sufficient in stock to meet present requirements. There have been large deliveries of birch, and the stock now stands at 6000ft. The stock of cedar, satinwood, and rosewood is very light, and there is a good demand. The market is overstocked with pencil cedar, and there is little demand.

University College, Liverpool.—Mr, Thomas L. Miller, Assoc.M.Inst.C.E., who has been for several years with Messrs. Fawcett, Preston, & Co., marine and general engineers, Liverpool, has been appointed to the post of Superintendent of the Walker engineering laboratories. Mr. Miller is well known in Liverpool as the late hon. secretary of the Liverpool Engineering Society. He has recently been awarded the special prize of £10 by the Polytechnic Society, for his paper on "The Use of Wrought Iron Mains."

SHEFFIELD, 13th June, 1888.

Iron and Steel.—The inquiry for heavy material is more encouraging. Orders for ordinary ship plates are being received, and there is a better inquiry for propellers and other maritime work. Bridge chains, girders for building, and roofing iron work also yield good employment. At the armour plate mills there is no great activity, but it is hoped the comparative quietude is only temporary. Colliery plant is selling well, particularly steel rope for hauling purposes. In railway material the demand keeps up. Tyres, axles, and springs are on large order; and all the rail makers are busy, the output being for foreign markets—chiefly Brazil, Japan, and India. The railway development in Japan is a striking example of the vigour and enterprise of that country. In addition to lines already in construction, many others are contemplated, and in the

Digitized by Google

next few months some large additional orders are expected. Engineers are tolerably well employed on heavy machinery, and in the boiler shops there is a satisfactory amount of work. One or two good orders have recently been placed for agricultural machinery; but on the whole this branch of trade is quiet. A brisk trade is being done in circular and hand saws. The dispute at Messrs. Slack, Sellars, and Co.'s is over. The men struck against a proposal to fix the week at fifty-four hours. They start work this week at fifty-two hours as the duration of the industrial week. In all descriptions of edge tools business is brisk, and there is a healthy tone in nearly all markets. The Merchandise Marks Act has already had the effect of increasing the prices of Sheffield made goods in some foreign markets. A profitable trade is being done just now in best descriptions of cutlery, and one or two Sheffield houses are kept busy in the surgical instrument branches, the trade in which is steadily increasing. There has been a decided increase in the demand for Bessemer and crucible within the past fortnight, and iron of all sorts finds a readier market, though the quotations show little change to the advantage of the merchants. Foundry pig can be bought at the furnace at from 33s. to 40s.; angles are selling at £5 to £5. 10s.; bars from £4. 10s. to £5 and £5. 10s.; hoops, £5 to £6; plates, £6 to £6. 15s.

Coal.—Many contracts have been concluded at old prices, and the pits should now be busier. Manufacturing, shipping, and railway needs are all large, and there is every prospect of an increasing demand for all sorts, with the exception, of course, of house coal. It is hoped that the dispute at the Hoyland Silkstone Colliery will be settled; the miners have claimed an extra 3d. per ton because the "end on" system of coal getting has been introduced. The extra price was not granted, so that the men came out, and left the Silkstone workings idle. The owners have given all the men a fortnight's notice, and unless an agreement is speedily come to the pits will cease to work altogether.

LEEDS, 13th June, 1888.

Iron and Steel.—Reports are rather better in the manufactured iron trade. There is no improvement in prices, but the demand is more satisfactory. At the furnaces and foundries work is more plentiful: in fact, since the Whitsuntide holidays, a steady and improving trade has been done. Some progress has been made also in the local steel manufacture, and it is probable that before long the consumers will not have to go elsewhere for their billets. The producers of heavy machinery have not been so busy for a long time. Messrs. Kitson's are busy on locomotives; Tannett & Co. on hydraulic machinery and other work; and Fowler's on engines for electric light supply, and other purposes. Some firms here are also doing well in railway material, and in tramway rails and engines. The agricultural machinery trade is quiet. Mill fittings are on better order, and engineers' tools continue in good request.

Coal.—The pits are only being worked four or five days a week, and the coal for shipment is scarcely up to the average. Still, manufacturing sorts are selling steadily; house coal is in slow demand, with falling prices.

NORTH STAFFORDSHIRE, 13th June, 1888.

North Staffordshire Railway Company.—A special meeting of this company was held at Stoke last week, when the shareholders approved the incorporation of the Shropshire Railways Company, and an Act for empowering them to acquire the Potteries, Shrewsbury, and North Wales Railway, and to carry out other arrangements. They also approved the construction of the railway from Cresswell to Cheadle. In neither case will any capital expenditure on the part of the North Staffordshire Company be involved, but mutual running powers have been agreed upon.

Newcastle Corporation Gas Works.—A report of the past year's working has now been issued, which shows a profit of £4,412, which enables the committee, after providing repayments of loans and sinking fund, to hand over £1,000 in relief of the rates. In the previous year a reduction of 6d. was made in the price of gas, and this has resulted in an enormous increase in the quantity of gas supplied. For the current year, contracts for coal have been secured on more favourable terms, and an advanced price is being obtained for residuals.

SOUTH WALES, 13th June, 1888.

Foreign Meat Industry.—This trade is assuming such large proportions in this district that at Newport new storage houses are in contemplation. A line of steamers engaged in this traffic trades regularly between Newport and the Brazils.

Coal Shipments.—The total shipments of coal, both foreign and coastwise, during the month of May, compare very favourably with the quantity exported in the same month of 1887. Taking Cardiff, Newport, Swansea, and Llanelly together, the total shipments last May amount to 1,290,275 tons, being an increase of 119,732 tons on May, 1887. Llanelly is fast rising into importance, having shipped 20,182 tons, showing an increase of 8110 tons over May, 1887. An experiment is now being tried with steamers trading between the Black Sea and the Belgium ports, which is likely to lead to a material increase in the sale of Welsh coals for bunkering purposes. Hitherto these steamers have had to purchase a large portion of the coal necessary to take the vessels home at something like 30s. a ton either at Malta or Gibraltar. By bunkering at Swansea, they will be able to take in sufficient coal for out and home voyages, which they are unable to do from the northern ports.

Cardiff and South Wales Exhibition.—The erection of the building for this Exhibition has already begun in the Howard Gardens, and will be completed by the 20th August. The reception of exhibits will then immediately commence. Mr. Philip Shrapnell, the manager, has obtained the certificate of the Board of Trade that the proposed undertaking is an international exhibition, which protects unregistered designs and unpatented inventions that may be sent in for exhibition, provided that the exhibitor gives the Comptroller the prescribed notice of his intention to exhibit, and that application for the patent or registration be made within six months from the date of the opening of the Exhibition.

BARROW-IN-FURNESS, 13th June, 1888.

The "Great Eastern."—Rumours have been afloat for some time that arrangements have been in progress for the beaching of the "Great Eastern" at Barrow, preliminary to the breaking up of the vessel. It is now announced that the dock authority has refused to allow her to be brought up Walney Channel, owing to the risk of her grounding in the harbour.

New Shipbuilding Orders.—The Pacific Steam Navigation Company, Limited, have entrusted the Naval Construction and Armaments Company, Limited, with an order for two large steamers for their mail service with the Pacific *viâ* the Straits of Magellan. These steamers are to be 430ft. long, 49ft. broad, 37ft. depth of hold, and they are to steam at the rate of 16 knots per hour. Other large orders are pending, including the thirteen steamers required by the Argentine Republic, the provisional contract for which has been signed.

Iron and Steel.—There is no change to note in the iron and steel trades. The improved tone reported last week is fully maintained; but there is no further increase in activity, or improvement in prices. There is reason to believe, however, that the consumption of pig iron will be maintained, and that the output of the district will not be reduced. There are upwards of 200,000 tons of hematite held in warrants in the North-west of England, and although these stocks have been reduced by about 6000 tons during the past few weeks, the great accumulation will prevent any increase in prices. 42s. per ton is still the price of mixed numbers of Bessemer pig iron net f.o.b., and 41s. is the value of No. 3 forge and foundry iron. There is no change to note in the industrial activity of the steel trade: makers are in receipt of as many orders as they can possibly cope with. Rails are in full output, as also are plates and angles, and the latter are again in fuller demand. Last week's prices are ruling. Iron ore remains very quiet, with prices ranging from 8s. to 10s. 6d. per ton net at mines for ordinary sorts.

MIDDLESBROUGH, 13th June, 1888.

Pig Iron.—The Cleveland pig iron market is firm, and prices are on the rise. That of No. 3 G.M.B. is 31s. 6d. for prompt delivery, and 31s. 9d. has been paid for the third quarter. Warrants are 31s. 7d. buyers and 31s. 9d. sellers cash for Connal's No. 3 G.M.B., and 42s. 6d. for Connal's hematite mixed numbers. Connal's store continues to decrease. The shipments have declined, but they are still much in advance of those of the similar period of last year. Those to Scotland have fallen off materially, and Germany and Holland still take the most.

Wrought Iron and Steel.—No change can be reported in these departments of trade. The mills are going steadily, with a fair amount of orders. The Darlington Iron and Steel Works Company have just issued their annual report; the preference shareholders get 7 per cent. per annum, and the ordinary 3s. per share. The Darlington Forge Company are enlarging their works, and the Newport Rolling Mills are to be started in the beginning of July, so that, so far as the amount of work is concerned, the prospect is encouraging. Prices are much the same—iron plates, £4. 17s. 6d.; angles, £4. 12s. 6d.; bars, £4. 15s.; steel plates, £6. 2s. 6d.; rails, £3. 15s., heavy sections. The strike at the ship yards has not affected the mills in the meantime.

Shipbuilding.—The ship yards are at a standstill. The men are much blamed, even by some of their own number, for not following the action of their own Executive. By their present attitude they are seriously risking the withdrawal of the 5 per cent. offered by the masters. The Stockton men would gladly go in on the masters' terms, but the Hartlepool men prevent them. They have already thrown away by their cessation from work a considerable portion of the good they would have obtained if they had continued. There is a growing inclination on the part of the men to resume work if the masters will agree to refer the matter to arbitration. As the men have abated their claim to 7½ per cent., and the masters have offered 5 per cent., this should not be a difficult matter to arrange.

SUNDERLAND, 13th June, 1888.

Shipping.—The trade of the last week was about the average; 75,441 tons of coal were shipped, of which 40,793 tons went coastwise and 34,648 tons were exported. 1742 tons of coke, 200 tons of patent fuel, 443 tons of cement, fire clay, and two cargoes of lime were also shipped. The imports for the week consisted of twelve cargoes of props, deals, oak and fir timber, three cargoes of silver sand, and two cargoes of iron ore.

Iron and Steel Works.—These works continue to be well employed. It is probable that a local limited liability company will be floated to re-start the Castletown Iron Works. It is proposed to erect two or four blast furnaces, so that the entire operations of iron and steel manufacture of plates, bars, &c., may be carried on. The works are situated on the north bank of the river, and have good deep water quayage. It is calculated that 200,000 tons of iron ore per annum will be required for these works.

Engineering.—Although the boiler makers obtained an increase of 1s. 6d. per week in their wages at the beginning of the present year, they are now demanding an additional 1s. per week, which the employers decline to grant. There is a feeling that at any moment there may be an entire stoppage in the establishments, owing to the various demands from the employés throughout the North-East Coast.

NEWCASTLE, 13th June, 1888.

Iron.—Though the orders in the hands of iron manufacturers are sufficient to keep the works in steady operation for some weeks to come, specifications for new contracts come in very slowly, and a period of dulness is expected. Prices do not show the degree of firmness that characterised them a short time ago, and in respect of new contracts that are now being negotiated, slightly reduced rates are likely to be accepted. Scrap iron is unusually plentiful at present, and the price has receded to 40s. per ton. Those manufacturers who are exceptionally well provided with prospective work for their rolling mills are taking the opportunity to accumulate scrap while it is cheap, and this circumstance must, of course, tend to bring about a reaction in favour of holders of the commodity. The announcement which was made in *Industries* some weeks ago, with reference to the early re-starting of the Walker blast furnaces, has now been verified, for one of the two furnaces has been put in operation, and the other will shortly be blown in. The re-starting of these furnaces has taken place at a most opportune moment, for the stocks of pig iron in the Cleveland district are being steadily reduced, and prices are tending upwards.

Steel.—The older steel manufacturing establishments, as well as those which have only recently commenced operations, are all somewhat overburdened with orders for the various classes of shipbuilding steel, and at Consett the pressure of work is particularly great. Should a stoppage of work take place in the Tyne shipyards, the activity in the steel works will be temporarily lessened, and manufacturers will have an opportunity of clearing off some of their most pressing engagements before taking upon themselves any new responsibilities.

The Chain and Anchor Trades.—The strike of chain makers at Messrs. Abbot's works, Gateshead, still continues, and it is understood that the firm are obtaining cable chain from Staffordshire to complete ships' outfits for which they had contracted. The firm have just put up in their anchor shop, a new and powerful steam hammer by Messrs. Davis & Primrose, of Leith, which is to be specially employed in the manufacture of Tyzack's patent anchors. Negotiations for fitting with these anchors a large fleet of steamers belonging to a foreign company are now in progress.

BELFAST, 13th June, 1888.

Shipbuilding.—Shipbuilders still continue to be fully employed, the stocks and finishing berths being well filled; but work has been greatly impeded during the past fortnight by bad weather. The riveters' strike for higher piece work rates in Messrs. Workman, Clark, & Co.'s yard still continues, and as the men are receiving support from their Society, they do not show any signs of yielding. There are several extensive repairs on hand.

Engineering.—The various branches of engineering are better employed than they have been for some time past. Marine shops are very busy, and are working overtime. Boiler makers are well stocked with work, and in some cases they hold large orders. Millwrights and machine makers are gradually extending their business, which was rather dull during the winter.

General Trade.—A slight improvement has been felt all round during the past month, and the number of men out of employment is at present small. Builders and contractors are very busy, and hold several important contracts. Manufacturers of aerated waters are doing an increasing business; and owing to the growing reputation of Belfast mineral waters, orders from abroad are larger and more numerous than they have ever been before.

Linen Trade.—The market has somewhat improved. The home trade has increased, both in volume and rates, and shipments are also becoming more regular. The higher numbers of yarns are in good demand, and prices are hardening. There is not, however, a corresponding advance in manufactured goods, though some firms have sought a slight advance without effect. An increase in prices all round may be expected at once; makers are growing firmer, as the stocks are small, and large orders are in hand. Handkerchiefs, both hand loom linen and cambric, have increased in price, and are difficult to obtain. Dyed and embroidered cambrics for costumes are in fair demand, and command a good price.

NEW LIGHTNING MAGAZINE RIFLE.

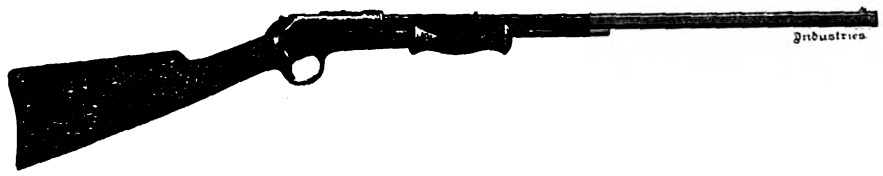

Fig. 1.

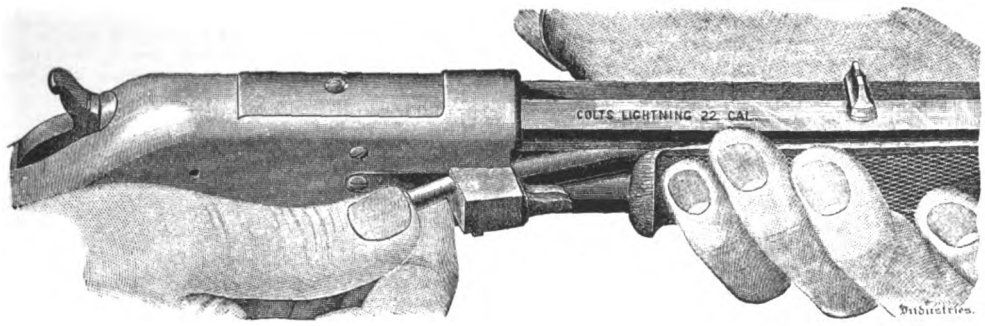

Fig. 2.

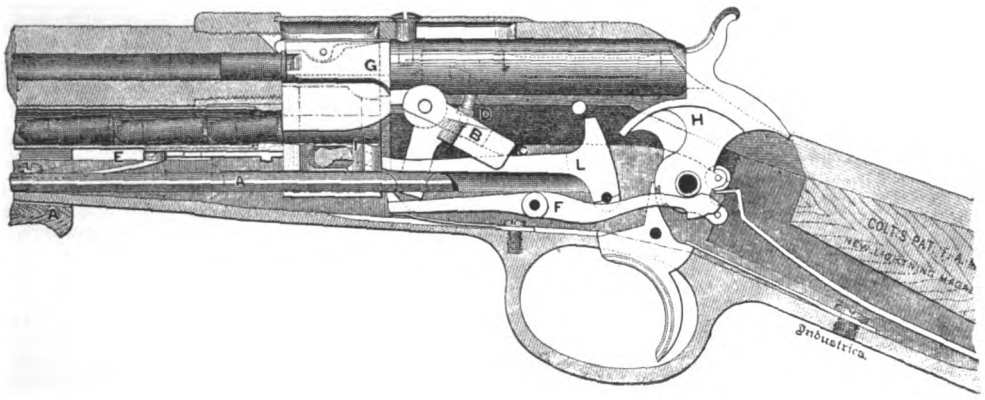

Fig. 3.

NEW LIGHTNING MAGAZINE RIFLE.

We are indebted to our American contemporary the *Iron Age* for the accompanying illustrations, showing a new lightning magazine rifle, ·22in. calibre, which has recently been brought out by Colt's Patent Fire Arms Manufacturing Company, Hartford, Connecticut. Fig. 1 gives a general view of the rifle, Fig. 2 illustrates the method of charging the magazine, and Fig. 3 gives a detailed view of the mechanism. One peculiar feature of this rifle is that either long or short ·22in. calibre cartridges may be used, the magazine holding fifteen of the former or sixteen of the latter kind. The magazine is either octagon or round, 24in. long, and weighs 5¾lb. and 6lb. respectively. The method of charging the magazine, as illustrated in Fig. 2, is as follows: The breech bolt being forward, and the hammer at half-cock or down, the left side of the magazine block is forced to the right with the thumb of the left hand, thereby exposing the mouth of the magazine. The cartridges are then introduced into the magazine tube in the manner shown in the illustration, each cartridge being pressed forward until its head rests against the loading spring just in the rear of the magazine block. When the required number of cartridges have been introduced, the magazine block is pressed back into its original position. The carrier I (Fig. 3) slides vertically, and is slightly raised by a cam on the slide A when the handle and breech bolt G are drawn back for opening the breech. By this arrangement the cartridges are held in the magazine after one cartridge has entered the carrier chamber, thereby obviating the use of a magazine gate. The forward end of the breech bolt G is fitted with a projection extending downwards, against which the cartridge rests when the bolt is drawn back, allowing the cartridge to move only in the same measure as the bolt. In this way the jumping of the cartridge through its entire length is obviated, and the danger of premature explosion greatly reduced. The spring E serves to lock the slide A in its forward position when the magazine block *e* has been moved outwards for charging the magazine; but when *e* has been returned to its position, the slide A is again unlocked. An empty cartridge is ejected and a new one introduced into the chamber in the following manner: The slide A is moved backwards by means of a wooden handle, thereby lifting the brace B and raising the carrier I to close the magazine. The same movement unlocks and draws backwards the breech bolt G, cocks the hammer H, ejects the empty cartridge, and raises the carrier lever L together with the carrier I, thereby bringing a fresh cartridge in line with the chamber. Now the slide A is moved forward, which motion pushes the breech bolt G forward and the

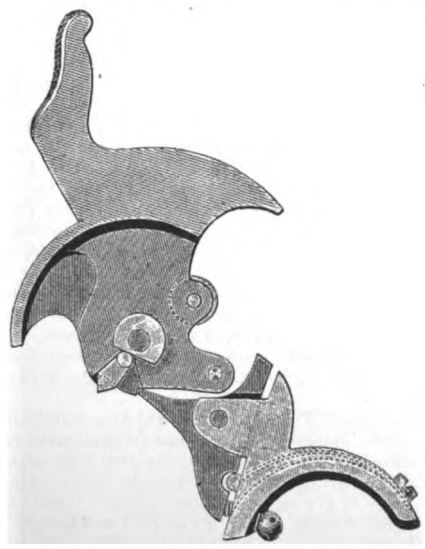

Fig. 4.

cartridge into the chamber, locks the breech bolt by the brace B, lowers the carrier, and opens the magazine for supplying a fresh cartridge to the carrier. The rifle is then ready for firing. The most important improvement is the automatic locking and unlocking of the hammer and the handle. Fig. 4 represents a patent set trigger used in the lightning rifles of ·44in., ·38in., and ·32in. calibre. The adjustment is made by means of a screw just above the place where the finger presses on the trigger. The action of this set trigger will be readily understood from the illustration.

COAL, IRON, AND COGNATE INDUSTRIES.

The Board of Trade Returns for the month of May must be regarded from a general point of view as being thoroughly satisfactory, though somewhat unfavourable in connection with the industries under review. The declared value of the imports shows an increase of £2,449,454, as compared with May, 1887, and of the exports an increase of £2,778,389, or nearly 17 per cent The total quantity of iron and steel exported last month was 388,403 tons, a decrease of 5021 tons, as compared with May of last year, the value showing an increase of £148,497. During the five months of the present year there has been a decline in our exports of pig iron amounting to 52,452 tons, and in value £232,820, as compared with the corresponding period of 1887. During May there was a large demand for crude metal from Norway and Sweden, and shipments showed an appreciable increase over April. The falling off to which we have frequently directed attention in the demand from America still continues, our exports to the United States being 20,000 tons less than in May, 1887. A decrease of 12,975 tons in quantity, and £46,266, or 9 per cent. in value, in railroad iron, is the most discouraging factor of the Returns; but on this point there is reason to believe that the apparent stagnation of foreign railway enterprise will not be prolonged. The figures relating to the copper markets are not very encouraging for the syndicate now controlling prices. It is a significant circumstance that unusually large supplies are being derived from unspecified and minor sources. On the export side of the account there is a falling off for the month of no less than 53 per cent. in quantity, representing at current rates a diminished value of over 21 per cent. We append our usual tabular statement:—

	Month of May.		Five months.	
	1888.	1887.	1888.	1887.
	£	£	£	£
Pig and puddled ...	250,458	280,721	855,613	1,088,433
Bar, angle, &c.	147,970	135,677	695,146	549,002
Railroad	443,753	490,019	1,996,481	1,555,176
Cast and wrought.	409,022	327,661	1,965,466	1,669,726
Hoops, sheets, &c.	372,415	239,721	1,661,413	1,229,396
Steel, unwrought...	166,592	176,147	596,468	905,567
Tin plates	507,583	526,444	2,286,707	1,958,600
Unwrought copper.	66,904	71,007	319,387	446,619
Coals	958,156	844,286	4,023,251	3,841,496

With regard to the home markets, the most noticeable feature has been the large shipments of Cleveland pig iron, the quantity dispatched during last month from the port of Middlesbrough being 107,826 tons, an increase of over 17,000 tons as compared with April, and of 33,300 tons as compared with May, 1887. Prices have been somewhat stronger, but remain on a low level in sympathy with Scotch warrants. In South Staffordshire the iron workers have argued their case for an advance in wages before the arbitrator to the Wages Board; but in face of the complete collapse in that centre of the revival of last autumn, both as regards prices and demand, their position is untenable and inopportune.

NAVAL ARCHITECTURE AT THE BRUSSELS EXHIBITION.

At the Brussels Exhibition a small but interesting sub-section is devoted to naval architecture, the exhibits in which will no doubt command both attention and admiration; the models in nearly all instances being beautiful specimens of the ship model maker's art. Messrs. Hawthorn & Co., of Leith, exhibit one full model and three half models. Two of their models represent the latest types of fishing trawlers. The Great Eastern Railway Company contribute exquisite models of the Harwich steamers "Norwich" and "Cambridge," built by Messrs. Earle, of Hull. The most interesting display of models are exhibited by the eminent Clyde shipbuilders, Messrs. William Denny & Brothers, of Dumbarton. This firm has five full models on exhibition, representing various types of vessels, from fast passenger and mail boats to light draught paddle steamers, specially constructed for river service. Their collection consists of: (1) A full rigged model of the s.s. "Mararoa," owned by the Union Steamship Company of New Zealand. The "Mararoa" is 320ft. long and 42ft. broad, and is at present engaged in the mail service between Auckland and San Francisco. (2) Model of the Peninsular and Oriental mail and passenger steamer "Clyde." The dimensions of the "Clyde" are: Length between perpendiculars, 390ft.; breadth, 42ft.; and depth, 35ft.; tonnage, gross register, 4100. (3) Model of the dispatch paddle steamer "Lucinda," owned by the Queensland Government. (4) Model of the two-decked light draught paddle steamer "Do-woon," owned by the Irrawaddy Flotilla Company. (5) Model of the "Elk," which was for some time employed in the Belfast mail service. Messrs. William Denny & Brothers have also a large number of models in the Glasgow International Exhibition.

Advertisements intended for insertion in the current week's issue must reach the Manchester Offices not later than first mail delivery on Thursday morning. Scale of charges for displayed advertisements on cover and inside pages will be forwarded on application. Orders for single advertisements must be accompanied by payment in order to insure insertion, the charge for which is 2s. 6d. for the first four lines or under, and 8d. for each additional line; one inch and over at 7s. per inch; the line averages eight words. While all practical regularity in the insertion of serial advertisements will be observed, it can only be absolutely guaranteed in the case of those ordered to appear weekly.

All accounts are payable to the Publisher, JAMES F. BUTTERWORTH, *70, Market-Street, Manchester. Cheques should be crossed Manchester and Liverpool District Bank, King-street Branch, Manchester. Post Office Orders to be made payable at Manchester.*

FRIDAY, 15TH JUNE, 1888.

COAL GETTING MACHINES.

THE illustration and brief description of a new coal getting machine which we gave last week, directs attention to a question of no little importance, viz., the breaking down of a mass of coal from the seam, with a view to its extraction. It is one of considerable interest even outside the world of mining men. A great colliery explosion is a disaster of sufficient magnitude to disturb the whole nation, and it is a well ascertained fact that the greater number of these explosions have had their origin in a "shot" fired to break down the coal. Out of feelings of mere humanity, then, we cannot withhold our sympathy with the efforts which are being made to render these calamities of less frequent occurrence. But the question has an industrial as well as a humanitarian aspect. The cost of coal is largely affected by the means and methods employed in breaking it from the seam, and irrespective of the necessities imposed by the keen competition of rival producers, this fact is of general industrial importance, the cost of fuel being a weighty factor in every manufacturing undertaking. From another point of view the question invites attention. In no other branch of engineering, probably, has there been of late greater progress made than in this. Changes have occurred with kaleidoscopic variety and rapidity. These changes have been brought about by new discoveries in science, and by the necessity of lessening the risks to which coal miners are exposed. As they have followed so quickly one upon another, we find most of the expedients devised in simultaneous operation. Time has not yet removed the least fitting among them. In this state of things we have thought it desirable to set forth briefly the improvements made in recent years, so as to be able to form an accurate estimate of the situation. Without this knowledge, it is scarcely possible to appraise at its true value such machines as that of Messrs. Roberts-Horsfield & Porter, to which we have already alluded.

For the information of those of our readers who may have no practical knowledge of mining, we may state that the work of coal getting involves two distinct operations, each of which is performed by a special set or gang of men. The hewers, who are the most highly paid workmen in the mine, hew away, or "hole," as it is technically called, the under clay, on which the coal seam usually rests, for the purpose of leaving the latter unsupported. The "holing" extends inwards to a depth of about 3ft. To perform this hewing, the miner lies on his side, and towards the end of the operation is partly beneath the projecting or unsupported mass of coal. When the latter is of a weak character, it is apt to fall and crush the hewer. Here lies the danger of the work, and the long lists of killed and maimed annually published in the Government Inspector's reports show that the risk to which the hewer is exposed is no trifling one. There is no remedy for this evil but the substitution of machine for hand labour. Hitherto but little progress has been made in this direction, on account of the great practical difficulties encountered. The work of the "getters," who follow the hewers, involves dangers of another character. Their task is to break down, or "fall," the coal which has been undercut. In former times this was effected by means of wedges driven in above, between the seam and the overlying rock or roof. But this process was slow and tedious, and consequently costly, especially when the coal was hard and strong. Very soon then it became the practice to blast down the coal by means of gunpowder. To effect this, a hole is drilled in the upper part of the coal, or in the roof clay above, charged, and fired, this "shot" being sufficient in most cases to break down the mass. But if the coal be very strong, or the hole badly "tamped," the shot will "blow out" like the charge from a gun, projecting a long tongue of flame into the dust laden and sometimes fiery atmosphere of the working places. Here lies the danger of the work of the getters. A large proportion, in the opinion of many competent judges the greater number of the disastrous colliery explosions which have occurred, have owed their origin to a "shot." It was demonstrated by the German experimenters at Neunkirchen that a "blown out" shot is capable of igniting, not merely an atmosphere rendered explosive by the presence of fire damp, but one that is laden with coal dust only. These results have been verified by the British Royal Commission on Accidents in Mines. The acquisition of this knowledge led to legislative action, and restrictions were imposed on shot firing. The inconvenience arising from these restrictions, and the danger which still existed when every possible precaution had been taken, forced mining engineers to look about them for a substitute for blasting. The want served as a stimulant to inventive genius, and various devices have been offered. First we had the lime cartridge. This is a charge of quicklime, which when placed in the bore hole, and wetted by means of a pump to force in water, generates great heat and expands. If the coal is not very strong, the lime cartridge is effective. But not being generally applicable, and being besides less simple in its application than powder, it has not come into common use. The attention of inventors was thus perforce turned back upon the wedge. The outcome of their efforts is to be seen in three machines now competing for public favour. The first of these, in the order of time, is Burnett's roller wedge, described in our issue of the 13th August, 1886. This is a machine worked by lever and screw, the wedge acted upon moving over rollers to diminish friction. Experience has shown that Burnett's invention fulfils all the conditions in a very satisfactory manner. Next we have Herr von Walcher's hydraulic coal getter, also described by us in our issue of the 8th October, 1886. In this machine the expansive power is obtained by hydraulic pressure through the medium of a small hand pump, the whole apparatus being easily portable. Walcher's machine is being used with very satisfactory results in a number of collieries in Austria, the country of the invention. Lastly, we have the Roberts-Horsfield & Porter machine, the first public trial of which we briefly chronicled last week. This is another hydraulic machine, differing, however, considerably in construction and mode of action from that of Von Walcher's. The two former have proved themselves capable of dealing effectively with every class of coal seam, and there is no reason to think that the more recent invention of Messrs. Roberts-Horsfield & Porter is in any respect inferior to its predecessors.

Though the use of these machines as a substitute for explosives occasions a small increase in the cost of getting coal, the difference would not be proved a

Digitized by Google

bar to their general adoption if no improvements had been made in the system of blasting. But here, too, inventors have been busy. We have in the first place, the devices introduced by Mr. Francis and Mr. Johnson, of preventing blown out shots by their system of expanding plugs. Then we have the invention of the water shield, a layer of water surrounding the charge, whereby the flame of the explosion is quenched. And last, and most important, there is the discovery of a flameless explosive, a discovery due to the Germans. Carbonite and roburite have been tested under every possible condition in fiery and dusty atmospheres, and found to be perfectly safe. Here, then, we come back to the old system of shot firing, but shorn of its dangers without losing its simplicity. To an unprejudiced mind it must be evident that the contest henceforth lies between this class of explosive and such machines as we have mentioned. What the ultimate result will be it is yet too early to predict. The system of blasting possesses the advantages of simplicity and economy; the method of breaking down with machines affords absolute safety. Moreover, it is to be borne in mind that the difference in favour of the explosive in the matter of simplicity and economy is but small. In a moderately tender coal the difference of cost would often disappear, because the machine will make less small coal than the blast. But here again we must not forget that small coal is becoming more valuable. On the other hand, a properly organised system of working may cheapen the labour of machine "falling." Abundant evidence of this is afforded by recent trials in the collieries of Western Germany. The inventors of "coal getters" will therefore do well to give attention to this matter. The future, and it may be a date not far distant, will bring improvements in electric lighting, and when every form of combustion lamp is excluded from a fiery colliery, it may appear inconsistent to introduce the risks, small though they be, of blasting with the flameless explosives, fired, as they must necessarily be, by fulminate detonators ignited by electric fuses. The prospect, therefore, is not discouraging for those who are spending their energy and their money in efforts to improve the class of machines of which the Roberts-Horsfield & Porter hydraulic "getter" is the latest type.

DOCKYARD v. PRIVATE CONTRACT WORK.

I.

Of all the great departments of State, the British navy has of late attracted most public attention. There have been many inquiries into its administration, resulting in many changes of *personnel* and system. The public purse has found some capable and earnest exponents and apologists, while the navy has had, as usual, its fair share of representation in the House of Commons, where the services are, on the whole, better represented than any other interest in the country. The outcome of the whole matter is a general admission that although we are, as a naval Power, more than equal to any other Power in Europe, our strength is not so greatly superior to that of other naval Powers as, considering our insular position, the great extent and value of our commerce, and our high naval prestige, it ought to be. For these reasons, there is a strong demand on the part of naval authorities for a still higher expenditure, and we are confronted with the prospect of the Goverment having to call upon the British taxpayer for additional supplies, in order that the alarmist demands of the naval experts may be complied with. In these circumstances it is fit that we should inquire how far Admiralty expenditure has hitherto been justified by its results; and how far the recent inquiries into the administration of the navy, and the humiliating exposures of incapacity, wastefulness, and corruption which they brought out, have been so far remedied. This inquiry is necessarily one which, to deal with it exhaustively, would require us to cover a good deal of ground. It may, however, be compressed, as regards its salient features, into the following questions: (1) Is Admiralty work as cheap and as efficient as it should be, relatively to private contract work? (2) Do private shipbuilders obtain a fair share of the work under Admiralty control? (3) Would the public interest suffer by giving out more work to private firms?

It may possibly be among the "things not generally known," that the British Government is at once the largest manufacturer, the largest store keeper, the largest employer of skilled or artisan labour, and the largest consumer of commodities of any firm, corporation, or state in the wide world. A glance at the alphabetically arranged lists of articles produced at Government establishments will show that there is hardly an article necessary for the outfit of vessels which is not produced in one or other of the Government establishments. The Admiralty produces at the royal dockyards ropes, rigging, sails, colours, masts, capstans, boats, blocks, oars, oakum, pitch, wheels, hose, boilers, torpedoes—practically everything required in the construction and equipment of ships, and the ships themselves, from the smallest to the largest craft. It produces at Woolwich, in the royal carriage department, hydraulic buffers, cans, tins, canteens, carriages, cartouches, carts, cases, chests, clips, composition, covers, deflectors, drugs, drums, dubbing, forges, guides, gear, hoops, jacks, lifts, levers, limbers, pads, pans, planks, platforms, pontoons, posts, rammers, ropes, saddles, shafts, shoes, sponges, tables, tools, telegraph equipment, and waggons. In the royal gun factories, it turns out every variety of iron and steel manufactures, including bolts, brackets, bronze carriers, clips, discs, hammers, handles, guides, levers, links, pins, plates, scales, screws, slides, sockets, spiral springs, strips, studs, straps, trays, vents, wrenches, and washers. In the royal laboratory at Woolwich, it produces caps, cartridges, gun cotton bags, cylinders, detonators, fuses, gas checks, gauges, hoops, fuse and shell implements, lithographs, quick matches, mallets, stencil plates, metal plugs, primers, props, rimers, rockets, shells, shot, stands, sticks for rockets, Whitehead torpedoes, tubes, wads, and washers. The victualling yards at Deptford, Gosport, and Plymouth are engaged in the manufacture of flour, biscuits, bread, oatmeal, chocolate, mustard, navy beds, bed covers, frocks, shirts, &c. The manufacture of rifles swords, sabres, bayonets, &c., is carried on at Enfield and Birmingham; that of gun cotton and powder at Waltham Abbey; and that of gas, &c., at Woolwich. Finally, it is the business of the State to superintend at Pimlico one of the largest factories in the world for the manufacture of clothing for our soldiers and sailors.

Lord Brassey, in his "Naval Annual," states quite truly that "there are inherent difficulties in the management of industrial operations by a public department;" but in spite of this well attested fact, the British Government has from time to time extended the range and complexity of its manufacturing business, until it would now be difficult to name any commodity that is in everyday use on a scale of any magnitude which it does not produce. In all this there is one redeeming feature—it does not come into the open market, and compete with private manufacturers. But it does almost, if not quite, as unjustifiable an act. It undertakes the production of very many articles that could be made cheaper, if not better, by private contract. It retains in its own hands a multiplicity of operations over which it is impossible that it can exercise an adequate control. We shall see, by and bye, that there is a consequent serious loss alike of efficiency and economy, which can hardly be excused on the plea that it is necessary that the State should be in a position, in cases of great emergency, to supply all its own needs.

The value of the various manufacturing establishments carried on by the Government is returned in the latest estimates for the army and navy at a grand total of £15,178,000. Of this amount, about £14,000,000 is set down to the various dockyards, £700,000 to Woolwich Arsenal, and the remainder to the small arms factories, &c. The artificers and workmen of all kinds employed number upwards of 40,000, and the amount paid in wages during 1886 was £2,266,000 sterling.

The first thing that occurs to a business man in looking at these figures, is to inquire what provision is made in the estimates for depreciation and interest on invested capital in respect of this vast expenditure. If such an expenditure had been incurred by a private firm in providing works for any business whatsoever, it would be necessary to allow at least 10 per cent. for depreciation and 5 per cent. for interest. This would involve setting aside two sums annually—the first amounting to £1,517,800, and the second to £758,900, or together £2,276,700, which would be equal to 17 per cent. of the total nominal amount of the navy estimates in each of the last two years. But in the case of the Government dockyards no such provision appears to have been made, and thus, to begin with, the dockyards and private shipbuilders do not start fair. Until the two are put on exactly the same footing as regards the financial arrangements entailed by capital expenditure, it is impossible to say that private builders have a fair chance of competing with dockyard work.

After making provision for amortisation of capital, the private shipbuilder requires to consider the two main elements involved in the cost of production, viz., the rates of wages that he would be required to pay for labour, and the prices at which he can purchase his materials. There are no exact data given in the Government returns as to the average rates of wages paid to artisans of different grades at different times, and therefore it is not an easy matter to compare one period with another, nor to institute a comparison of Her Majesty's dockyards with private shipbuilding establishments. The returns do, however, demonstrate two facts beyond all question—the first, that the average rate of wages paid in the dockyards is much higher, taking one department with another, than would be paid in most of the private shipbuilding yards in the country; and the second, that the cost of superintendence is very much in excess of what would be paid in any private shipbuilding works.

The following is a statement of the numbers recently employed and the amount paid in wages in the different dockyards over a period of twelve months:—

Dockyard.	Employés.	Wages paid.	Average wages per employé per annum.
Chatham	4221	£278,000	£65·9
Sheerness	1670	113,000	67·7
Portsmouth	5660	384,000	67·8
Devonport	4594	298,000	64·8
Pembroke	2190	138,700	63·3
Totals	18,335	1,212,200	66·1

In this statement the average amount of wages paid per employé over the year appears to be £66·1, or 25s. 6d. per week. This may be regarded as low rather than high, and if the average applied to skilled artisans no doubt it would be a low average. But the average includes boys and common labourers, and if we could state exactly the proportions of each of those classes it would probably be found that the average of the dockyards was considerably above the average of ordinary private yards. Nor must it be forgotten that men who are on the regular establishment are entitled, in the case of dockyard labour, to a pension after so many years of service, which should affect their wages considerably. As regards supervision, the latest returns show the following remarkable results:—

Number of Officials and Amount of their Salaries at Her Majesty's Dockyards.

Dockyard.	No. of officials.	Amount of salaries.	Average per head.
Portsmouth	306	£52,380	£170
Devonport	241	42,985	179
Chatham	198	34,804	176
Sheerness	120	21,896	182
Pembroke	86	16,771	195
Deptford	15	2,955	196
Portland depôt	2	680	340

The total number of officials in these dockyards as a whole is 968, and their united salaries amount to £172,471, or an average of about £180 each. The total number of artificers of all kinds employed in the same dockyards is 19,554, so that there is one official to every twenty workmen. Let this be compared with the practice of our private shipbuilding yards, and the Admiralty system will be found greatly more expensive. There are several shipbuilding works in this country that employ a larger number of hands than any one of the dockyards, when trade is fairly good. Such firms as the Fairfield Company on the Clyde, and Palmers' Shipbuilding Company on the Tyne, sometimes run up to 6000 or 7000 hands; but they do not expend on supervision more than 5 per cent. of the total amount paid as wages to their emyloyés, whereas in some of the dockyards the cost of superintendence is 20 per cent. of the total sum expended in wages. Economical work is, under these circumstances, all but impossible.

THE NEW INDUSTRIAL ERA IN INDIA.

A few weeks ago we directed attention to the rapid progress which was being made in Japan in industrial enterprise, and pointed out the probable competition we should have with that country for the foreign trade of China. People in this part of the world are too apt to look upon the Japanese as mere producers of curios and of peculiar art wares, and seldom realise the possibility of them developing into active manufacturers. In the same way the India of the imaginations of many is that of a country which produced curiosities, and whose people carried on a retail trade in luxuries. The India of to-day is really a wholesale producer of staples, with an enormous export business.

Sir William Hunter, LL.D., in a recent paper read before the Colonial Institute, pointed out very forcibly that India was now entering the market as a competitor with the British workman—with the farm labourer as with the mill hand—and that before long she would appear in competition with the British capitalist. He believed that the development of India as a manufacturing and food exporting country would involve changes in English production, which must for a time be attended by suffering and loss. The essential competition between India and Europe was now the competition between the productive powers of the tropics and of the temperate zone. This competition in heavy and bulky staples had been rendered possible by the new era in the Indian carrying trade, represented by railways, steam naviga-

Digitized by Google

tion, and the Suez Canal. In 1834 the exports from India were valued at 9½ millions sterling. During the next twenty years they amounted to an average of 20 millions for the five years ending 1854. The following twenty years marked the introduction of railways into India, the development of steam shipping *viâ* the Cape, and the opening of the Suez Canal; and the exports expanded to an average of 57 millions for the five years ending 1874. During the next ten years the influences of the Indian railways, of steam navigation, and of the Suez Canal, came into full work. Indian trade advanced by rapid strides, until in 1884 the exports of merchandise had reached the enormous total of 88 millions sterling. Wheat had always been one of the principal crops in India; but until 1873 the export trade in it laboured under duty, and the amount exported in that year was only 1,750,000cwt. Since the abolition of the duty, the export has increased to 21,000,000cwt., and the agricultural returns show not only the large increase that has taken place in the wheat acreage, but that it was still capable of much larger increase. Oil seeds have a similar history from 1875, when they were freed from their export duty. Up to that date their average exportation had been about 4,000,000cwt. a year, while in 1885 it had grown to 18,000,000cwt. But not only had there been an extended production of agricultural staples for sale in Europe, but also a re-organisation of the manufacturing system in India. Thirty years ago the ruin of Indian cotton manufactures seemed final and complete; but that proved only a transition stage. The hand loom of India was almost crushed out; but the industry was about to arise in a new form. A mill for the manufacture of cotton yarn and cloth was set up in Bombay in 1854. By 1884 there were over one hundred cotton and jute mills at work in India, with 22,000 looms, 2,000,000 spindles, and giving employment to over 110,000 people; and even the rapid progress indicated by these figures was merely the commencement of a great industrial development, whose eventual dimensions it was almost impossible to foresee. Coal mining was being developed, and the difficulties in the application of Indian coal had been so far got over that ⅞ths of the coal used in Bengal, with its great railway system and its steam industries, were now raised in the country. Dr. Hunter concluded his paper by enlarging on the generalisation that the world was now entering on a new era of competition—the competition between the productive powers of the tropics and of the temperate zone—and he expressed his conviction that Indian wheat and Indian jute bags and cotton goods were only the forerunners of other commodities in which India was destined to compete keenly with the English producer. Down to the present age, India had been practically disqualified in the competition of the bulkier agricultural staples (common to India and England) by distance and the cost of carriage, by want of steam power, and by the absence of the association of labour and capital on a large scale. During the past thirty years these had been largely removed, and during the next thirty years they would entirely disappear, and in the meantime a whole series of economic questions of the first magnitude were impending—questions which only an English statesman of the first class would have the courage and authority to deal with effectively. If these were properly managed, India's gain would not be England's loss. It would, in the end, be a gain to England in common with the whole world. In the meantime, however, careful attention should be given to the questions involved, both by statesmen and commercial men.

Letters to the Editor.

NICOLA TESLA'S ALTERNATING CURRENT MOTOR.

To the Editor of "Industries."

Sir,—The very interesting researches of Mr. Tesla, which you published in the last number of your valuable paper, will no doubt open a new field of investigation in the direction of applying alternating currents for motive power purposes; but, as you say, the solution does not seem to be perfect in its present form. It is open to several objections, which will readily occur to practical engineers, and the following appear to me to be the most important: (1) The necessity of a three-wire system of distribution (a system which answers very well for direct distribution by means of continuous currents, the e.m.f. of which ought not to exceed a certain value) seems to be a step backward in the case of alternating currents with transformers, where a very high e.m.f. can be used without any inconvenience, being, in fact, the main advantage of the system. (2) Motors on this system would have to be placed in the primary circuit, a circumstance which is not without its dangers in those cases where it is feasible, viz., when there is a transformer to every house; and which becomes an impossibility when, as is the case on the Continent and in America, one large transformer feeds the secondary mains of a whole sub-district. (3) I hardly think that it will be generally agreed with Mr. Tesla that his ring must form the most efficient type of transformer. It is certainly true that the shifting round of the magnetism in the core is more advantageous against hysteresis than rapid reversals of the magnetic field. But, on the other hand, Mr. Tesla's ring does not form a closed magnetic circuit. It has apparent poles diametrically situated; and even if covered over with an iron shell, so as to diminish the magnetic resistance of the combination, there would still be the objection of the air space occupied by the coils, and across which the lines of force would have to leap—a disadvantage which does not exist with ordinary transformers of the ring or shell type. Far from underrating Mr. Tesla's work, I think that the admirable solution he has given of the transmission of energy by means of alternating currents cannot be too much praised. But the question is still in its infancy, and much remains to be done to render it thoroughly practical.

Yours, &c.,
L. H. Despeissis.

25, Rue de Naples, Paris, 11th June, 1888.

THE ELECTROLYSIS OF MERCURY BY THE ACTION OF AN ALTERNATING CURRENT OF ELECTRICITY.

To the Editor of "Industries."

Sir,—Perhaps it will be of interest to some readers of your valuable paper, to know of the peculiar behaviour of two mercury electrodes placed a short distance apart in dilute sulphuric acid, when an alternating current of electricity is passed from one electrode to the other through the dilute sulphuric acid. As soon as a current is caused to flow, the mercury becomes agitated and presents a beautiful wavy appearance on its surface, which increases in its agitation as the current strength increases. The mercury at the same time is attacked by the acid and forms an insoluble sulphate which rises with the hydrogen, which is liberated at the surface of the mercury, in a cloudy form, and slowly falls to the bottom of the cell. This peculiar phenomenon is of great scientific interest, as this sulphate is formed in proportion to the current passing; consequently the mercury loses in weight in the same proportion. We made these discoveries in the course of an extended series of experiments to overcome the difficulty of metering alternating currents. Owing, however, to many mechanical difficulties in the rise of mercury, the idea to use this as a meter was abandoned. Further searches resulted in a successful issue, and we hope to shortly publish an account of the working of our meter.

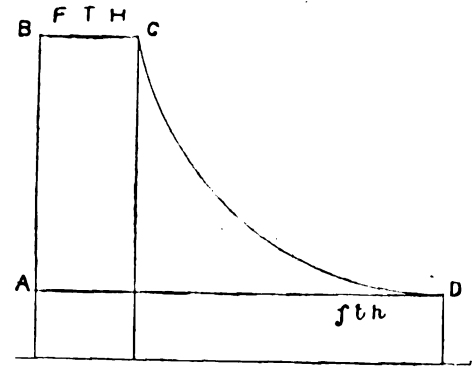
Yours, &c.,
Eastbourne, 6th June, 1888. Lowrie-Hall.

FUEL TESTING LABORATORY.

To the Editor of "Industries."

Sir,—While fully agreeing with the excellent suggestions, and recognising the value of the information, given by Mr. Bryan Donkin, I wish to draw your attention to the fact that the suggestion of a public fuel testing station is not new, as it was proposed in a paper read by Mr. B. H. Thwaite, C.E., on "Fuel Calorimetry" (see *Industries*, Vol. I., page 276), at the British Association of 1886. The Gaseous Supply Company, Limited, has for its object the establishment of fuel testing stations, so that Mr. Donkin's views are very soon likely to be carried into practical effect.

Yours, &c.,
Silverdale, Carnforth, 9th June, 1888. J. B.



PETROLEUM VAPOUR ENGINES.

By G. R. Bodmer.

The experiments made by Mr. Yarrow with petroleum spirit or similar distillate of mineral oil as a "working substance" in the cylinder of an engine has, owing to the remarkable results obtained, excited so much interest among those concerned with the problems involved in the application of heat to the production of motive power, that a somewhat detailed inquiry into the principles and theory underlying the action of motors of this kind may not be out of place, more especially as it has been suggested that the results obtained by Mr. Yarrow are not in harmony with some of the generally accepted fundamental principles of the theory of heat. The engine in question is simply an ordinary steam engine, to which, however, instead of steam, the vapour of petroleum spirit is supplied as a working substance. The vapour is generated in a copper coil, through which the spirit is forced by a small feed pump, the exhaust being condensed in pipes passing through the water on the outside of the launch, and terminating in a small tank in the bows of the vessel, from which the condensed spirit is again drawn by the feed pump, so that the liquid is continuously circulated and used over and over again. Either a portion of the vapour itself is burned as fuel for heating the copper coil, or ordinary petroleum, gas, or any convenient substance can be employed. In the experiments already described in *Industries*, the fuel used was ordinary coal gas. The engine was first worked with ordinary steam generated in a "Field" boiler, and the consumption of gas for a given power, measured on a Prony brake, observed. Afterwards petroleum spirit was circulated through the copper coils, enclosed in this instance in the steam space of the Field boiler, and the power developed with the same expenditure of coal gas ascertained. It was found that with the spirit vapour about twice as much power was obtained by the same consumption of fuel as when steam was used for working.

Considering the very numerous factors, of a theoretically subordinate but practically very important character, which determine the economy of a steam or vapour engine, it seems rather rash, on the strength of the above recorded results, to jump to the conclusion that the foundations of the mechanical theory of heat are insecure. From the experiments made by Mr. Yarrow, it appears that of the particular oil distillate used by him about nine times as much can be evaporated under atmospheric pressure as of water, with a given quantity of fuel; that is to say, the heat of evaporation of the petroleum spirit vapour is only about one-ninth that of saturated steam. At the temperature corresponding to a steam pressure of 50lb. per square inch, the pressure of the petroleum spirit vapour is 75lb., and its boiling point at atmospheric pressure 180°F. Working between the same temperatures, the spirit vapour would therefore have higher initial and terminal pressures than saturated steam, and with the same volume and a given expansion ratio do more work than the latter; on the other hand, the density being higher, a greater weight of the vapour would be required to do this work. In dealing with the subject from the theoretical point of view, it is more convenient to use the temperatures and quantities of heat required than pressures and volumes, more especially as the fluid heat and heat of evaporation have been determined by direct experiment, and can be introduced without further transformation into the calculations in a very simple manner.

The well known expression for the efficiency of a perfect heat engine, $E=\frac{T-t}{T}$, applies of course to steam and other vapours; but it should not be forgotten that this very simple formula is only applicable to one particular cycle, which never occurs in practical working, and the statement that the efficiency of a heat engine is entirely independent of the nature of the working substance employed, is only, as we shall show, unreservedly true of that cycle, although the deviations from the principle in other cases are very slight. In dealing with engines using vapour, we shall assume that the cycle employed is what may be called the "ideal practical cycle," represented by the annexed diagram A B C D in which the steam or vapour is expanded from the boiler or generator pressure P to the condenser pressure p, the corresponding absolute temperatures being T and t. As usual, all our investigations will, for the sake of convenience, be referred to one pound of the vapour under consideration.

The feed liquid supplied to the boiler is assumed to have the temperature t of the condenser; the heat therefore which has to be supplied to the boiler to produce one pound of the saturated vapour at the temperature T, is $F-f+H$, where F and f are respectively the fluid heats of the liquid at the temperatures T and t, while H is the heat required to convert one pound of liquid at the temperature T into saturated vapour of the same temperature. The heat of evaporation $F-f+H$ is therefore the quantity with which the work done by the substance has to be compared, to arrive at the efficiency as usually estimated.

The work represented by the diagram A B C D is expressed very nearly by

$$W=F-f+H-xh,$$

where h is the heat of evaporation of the vapour at the temperature t, and x the proportion of vapour to liquid present at the end of the expansion. This expression is quite accurate for calculating the indicated work less that required for feeding the boiler, the deduction of which signifies the formula. Previous to the cut-off the vapour is assumed to be dry. The efficiency is

$$E=\frac{F-f+H-xh}{F-f+H} \quad \ldots\ldots\ldots\ldots (1)$$

It must be borne in mind that this expression, in its general form, is quite independent of Carnot's principle and the second law of thermodynamics. All the quantities in it, with the exception of x, have been determined by direct experiment for various substances, and there is not a shadow of doubt as to its validity under the assumed conditions. The value of x, however, has to be determined by another formula, in which the second law of thermodynamics is involved; but as we shall prove, its influence does not in any way weaken our conclusions.

Digitized by Google

To avoid a separate calculation, the value for x must be substituted in the above equation for E, and to show its tendency more clearly the various quantities may be expressed in terms of the temperatures T and t; when this is done, we finally obtain

$$E=\frac{H\frac{T-t}{T}+C\left(T-t-t\log hyp\frac{T}{t}\right)}{H+C(T-t)} \quad \ldots\ldots\ldots (2)$$

where C denotes the specific heat of the liquid. This specific heat is in no case quite constant, and in some cases varies considerably with the temperature; but for those substances of which the fluid heat at various temperatures has been determined by Regnault, the average value of C for the particular range of temperature in question may be used in the formula (2).

On inspecting this formula it will be seen that the factor $\frac{T-t}{T}$, with which H is multiplied in the numerator, is nothing else than the efficiency of a perfect engine, and that by omitting in both numerator and denominator the portions multiplied with C, E becomes simply $\frac{T-t}{T}$.

Let us assume that

$$T=460°+302°=762°F.$$
$$t=460°+212°=672°F.$$

whence the range of temperature

$$T-t=90°;$$

then

$$\frac{T-t}{t}=0{\cdot}118,$$

and

$$\left(T-t-t\log hyp\frac{T}{t}\right)=6{\cdot}059.$$

The efficiency is

$$E=\frac{0{\cdot}118H+6{\cdot}059C}{H+90C} \quad \ldots\ldots\ldots (3)$$

We are now in a position to calculate for the assumed conditions the efficiency of an engine working with different substances, when for the latter we know the values H and C. It is obvious that the efficiency E can only be the same for all vapours, if H and C have a constant ratio to each other; this, however, as a glance at Regnault's tables will show, is by no means the case, and consequently, with any other cycle than Carnot's, the efficiency must depend more or less on the nature of the working substance.

The following is a summary of the results obtained with formula (3) for various vapours:—

Steam.

C=1·0224.
H=901·418 B.T.U. E=0·113.

Alcohol.

C=0·978.
H=306·864. E=0·107.

Chloroform.

C=0·245.
H=92·934. E=0·107.

Benzene.

C=0·373.
H=180. E=0·110.

Petroleum Spirit.

In this case we have no accurate data; but taking the heat of evaporation at one-ninth that of steam, as shown by Mr. Yarrow's experiment previously referred to, and the specific heat at 0·4, we have

C=0·4.
H=100. E=0·104.

As regards the value of x, it is, in every case we have considered, less than unity, showing that condensation occurs during adiabatic expansion. If no condensation took place, it is obvious, from formula (1), that the efficiency would be less. The introduction of x into the calculation tends therefore to increase the value of E, and in no way to eliminate the influence of the special character of the vapour used.

The figures we have given show that in spite of the varying proportion between the specific heat and the heat of evaporation, the efficiency of very different vapours under similar conditions is nearly the same for the most favourable cycle as carried out in steam engines, and that therefore we must look for some other than a purely theoretical explanation of the causes for the superior economy of petroleum spirit as compared with steam in the case of Mr. Yarrow's "Zephyr" engine.

In every one of the cases investigated, it will be seen that the efficiency is below that of the perfect engine, and decreases as the ratio of the specific heat to the heat of evaporation increases, so that for the extreme supposition that $\frac{H}{C}=0$

$$E=\frac{6{\cdot}059}{90}=0{\cdot}066.$$

These results all go to confirm—as might be anticipated—the established principles of the theory of heat, more especially of that associated with the name of Carnot.

Having shown that there is nothing in the general principles applying to the action of heat engines worked by vapour to account for the superiority of petroleum spirit over steam in the matter of economy, we come to the question: To what, then, is this superiority due? The two chief sources of loss in the production and utilisation of steam power are, first, the waste of fuel in the generator, and, secondly, the condensation of steam before the cut-off takes place on its admission to the cylinder. Any marked improvement in the performance of a given engine is, in all probability, due to a reduction in one or both of these losses, and if, therefore, a motor when using petroleum spirit is more economical than when using steam under otherwise similar conditions, the natural inference would be that the generator is more efficient for the production of petroleum vapour than for that of steam, and that the initial condensation in the cylinder is less for the former than for the latter. In a small engine, such as that with which Mr. Yarrow's trials were made, there is plenty of room for improvement under both heads when working with steam. It is not at all unlikely that the boiler when used simply as a steam bath for heating the coil through which the petroleum spirit was circulated was more efficient than under ordinary conditions. Owing to the fact that only about one-ninth of the quantity of heat was required to evaporate a given weight of the fluid, the circulation in the tubes would be very rapid, and favour the more effective utilisation of the heat supplied; but it is probably to a reduction in the initial cylinder condensation that we much look as the chief source of improvement.

To perform a given amount of work, a much greater weight of petroleum spirit vapour than of steam at the same temperature has to pass through the engine. Assuming the efficiency to be twice as great with petroleum vapour as with steam, the proportion of the former to the latter required would be $4\frac{1}{2}:1$, the heat of evaporation being taken as one-ninth that of steam. The initial pressure of the spirit vapour is about one and a half times that of the steam at the same temperature, and roughly speaking, therefore, with the same expansion ratio, the work done in the cylinder per stroke will be about one and a half times as great with spirit vapour as with steam, and consequently the weight of the vapour admitted at each stroke $4\frac{1}{2}\times 1\frac{1}{2}=6{\cdot}75$ times that of the steam. The surface of the cylinder walls concerned in producing initial condensation is the same per stroke in both cases, and at a given speed the time of exposure would be equal. The rate at which heat is transferred from the petroleum spirit vapour to the cylinder metal must therefore be much less than for steam, in order to account for the observed greater economy. It is well known that the rate of transmission of heat through a plate of, for instance, cast iron, from one fluid to another, varies considerably according to the nature of the latter; but no data are available on this point with regard to petroleum spirit or similar vapours. That such substances would, however, part far less readily with their heat than wet steam, seems highly probable, and a film of the condensed spirit once formed upon the surface of the cylinder walls must act as an effective non-conductor, whereas a similar film of water would facilitate the transference of heat.

If it be assumed that the quantity of heat abstracted by the walls of the cylinder, in a given time and for a given exposed area, with a certain range of temperature, is the same whatever be the vapour used, then there would still be an advantage in favour of the petroleum vapour, on account of the greater quantity of work done per stroke—that is to say, the condensation would be, approximately, no greater for $1\frac{1}{2}$ h.p. with vapour than for 1 h.p. with steam.

In the absence of detailed particulars of Mr. Yarrow's trials and indicator diagrams, it is, of course, impossible to come to any definite conclusion as to the causes of the reported superior economy of the "Zephyr" engine; and for this purpose it would be necessary to know, not merely the quantity of petroleum spirit circulated in the generator per i.h.p. per hour, but also the specific volumes of the vapour at various pressures, so that the amount of condensation at any point of the stroke could be determined, in the same manner as has been done in the case of steam.

One other point, which very possibly tells in favour of petroleum spirit, may in conclusion be mentioned. It is very generally believed that in steam engines the re-evaporation of a film of water adhering to the walls of the cylinder, on connecting it with the condenser, is largely instrumental in cooling down the metal, and thus causing subsequent initial condensation. If we assume a similar phenomenon to occur with petroleum vapour, it is tolerably certain that the adhering film of liquid cannot be thicker than in the case of steam; and as its specific gravity is less than that of water, the actual weight of the film must also be less. The heat of evaporation, however, is only about one-ninth that of steam, so that less than one-ninth of the cooling effect occurring with steam is produced by the re-evaporation of the film of petroleum spirit on the cylinder metal, and the capacity of the latter for subsequently absorbing heat is proportionately less.

CLYDE SHIPBUILDING FOR MAY.

The total tonnage launched during the month of May was 13,643 tons. The number of vessels, including six yachts, was twenty, so that the average tonnage was very low. The only vessel of note was the "Magicienne," a war cruiser for the British Government, launched by the Fairfield Engineering and Shipbuilding Company, Limited. The "Marathon," sister ship to the "Magicienne," will shortly be launched. Only one sailing vessel of 1200 tons was launched during the month. The new contracts do not involve a large addition to the work on hand. The order, booked in the end of April by Messrs. Scott & Co., Greenock, for two gunboats of 850 tons displacement each, to be named the "Sparrow" and "Thrush," is in course of execution. Messrs. Russell & Co., Port Glasgow, received an order from Messrs. Stewart Brothers, Glasgow, for two iron sailing vessels of about 1300 tons each. Mr. W. T Cumming has begun to build a new steel screw ferry boat, for the Clyde Trust. The other orders consist of a number of yachts, including two centre board boats. The following are the names and brief descriptions of the vessels launched during the month of May:—

War vessel: H.M.S. "Magicienne," twin screw, protected cruiser, 3000 tons displacement, 9000 i.h.p., built by the Fairfield Shipbuilding and Engineering Company, Limited Steamers: "Baltimore City," steel, 2334 tons, built by Messrs. A. Stephen & Sons, Linthouse, for Christopher Furness, West Hartlepool; "Ben Ledi," steel, 2300 tons, built by Messrs. Barclay, Curle, & Co., Whiteinch, for Messrs. Wm. Thomson & Co., Leith, for the tea trade; "Cayor," steel, 1084 tons, built by Messrs A. MacMillan and Son, Dumbarton, for Messrs. Deves & Chaumet, Bordeaux, for the African trade; "Lucy Ashton," paddle steamer, built by Messrs. T. B. Seath & Co., Rutherglen, for the West coast passenger traffic of the North British Railway Company; "Mavis," steel paddle steamer, built by Messrs. Scott & Co., Greenock, to the order of the General Steam Navigation Company, London; "Princess of Wales," saloon paddle steamer, built by Messrs. Barclay, Curle, & Co., Whiteinch, for the Isle of Wight and Southampton traffic of the Isle of Wight and South of England Royal Mail Steam Packet Company, Limited; "Sakkarah" and "Save," twin screw hopper barges, 400 tons each, built by Messrs. Lobnitz & Co., Renfrew, for the Suez Canal Company; "Sung Kiang," steel twin screw, 1650 tons, built by Messrs. Scott & Co., Greenock, for Chinese coasting trade, to the order of the China Navigation Company; screw steamer, 250 tons, built by Messrs. J. Fullarton & Co., Paisley, for Messrs. Richard Hughes & Co., Liverpool; also three steam launches and two steam yachts, including the "Ceto," 180-ton twin screw, built by Messrs. Napier, Shanks, and Bell, for Sir Edward Cecil Sumners, Bart. Sailing vessels: "Banklands," steel, 1239 tons, built by Messrs. John Reid and Co., Port Glasgow, to the order of Messrs. W. Just and Co., Liverpool; also three sailing yachts.

* Including three yachts, 248 tons. † Including three yachts, 37 tons.

Messrs. Fleming & Ferguson, shipbuilders, Paisley, have received an order for a steel screw steamer for the China trade, through Messrs. Russel & Spence, engineers, Glasgow. She is to have accommodation for about thirty first class passengers, and is to be fitted by the builders with their improved balanced quadruple engines, to indicate about 1800 h.p.

Steam Boiler Legislation.—On the 6th March last, Mr. Provand, member for one of the Glasgow divisions, brought in a Bill to amend the law relating to and providing for the compulsory examination of steam boilers. On the 5th inst. the order for this Bill was brought before the House of Commons and discharged, and the Bill withdrawn.

Milling Convention. — The annual convention of the National Association of British and Irish Millers is to be held at Plymouth, from the 3rd to the 6th of July. According to the provisional programme, the following will be the order of proceedings: Tuesday, 3rd July: Reception by the Mayor and Corporation. Annual meeting of the Council. Election of president, officers, &c. Paper by Mr. Alph Steiger, on the "Selection of Water Motors for Flour Mills." Visit to Keyham yard. Annual dinner. Wednesday, 4th July: Trip up the river Tamar. Thursday, 5th July: Trip round the Eddystone lighthouse. Paper by Mr. J. H. Carter, on "Pneumatic Sorting." Paper by Mr. H. Simon, on "Haggenmacher's New Patent Scalper." Paper by Mr. J. Salkeld Robinson, subject not yet fixed. Friday, 6th July: Visit in war boats to witness big gun drill and torpedo practice at Devonport. Several mills will be open for the inspection of members.

ELECTRIC LIGHT INSTALLATION AT THE BOTANICAL GARDENS, MANCHESTER.

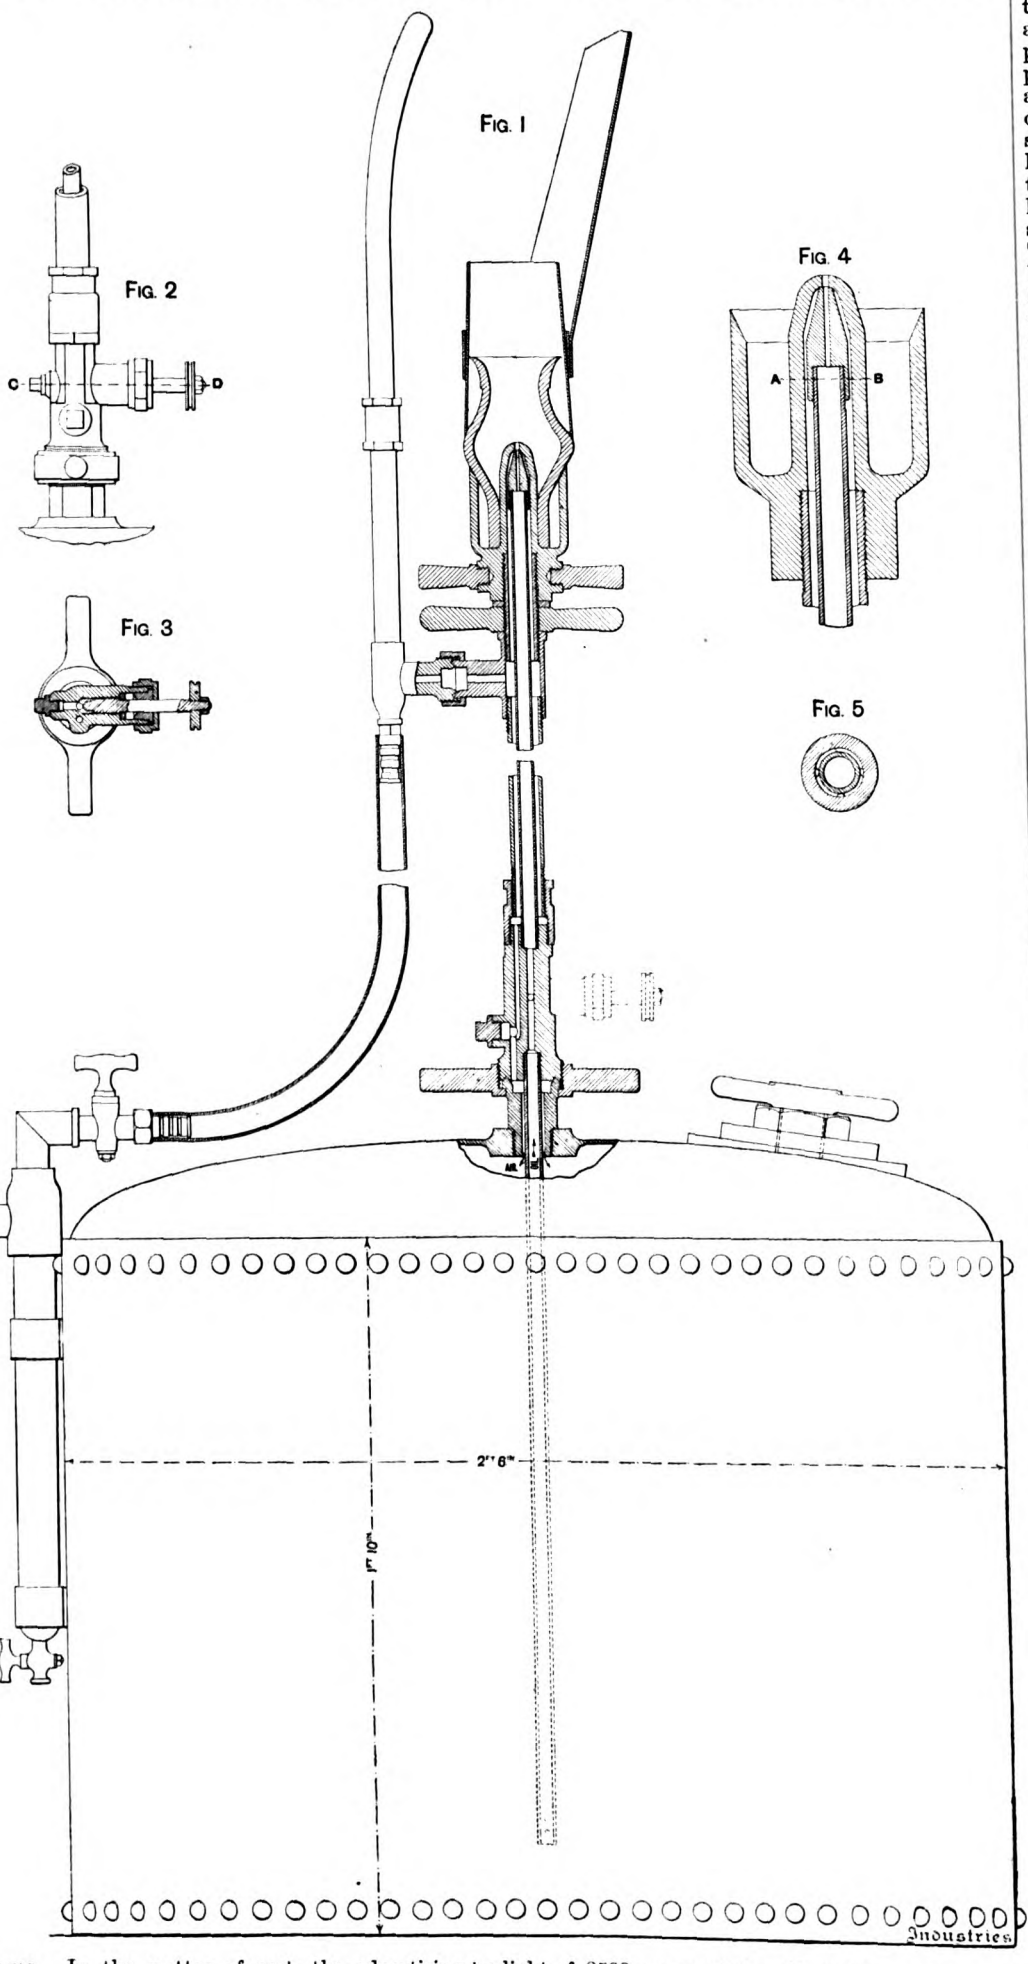
On Thursday, the 7th inst., we had an opportunity of witnessing a trial of the electric light installation at the Botanical Gardens, Old Trafford, Manchester, which, it may be recollected, formed part of the late Royal Jubilee Exhibition. The installation has been erected by the Manchester Edison-Swan Company, Limited, for supplying the current for fifty-six arc lamps each of 2000 n.c.p. The combined boiler and engine, which we herewith illustrate, has been constructed by Messrs. Marshall, Sons, & Co., Limited, Gainsborough, and was erected by Messrs. J. B. Welch & Co., Market-street, Manchester. As will be seen from our illustration, the engine is fixed on a strong wrought iron frame under a locomotive multitubular boiler, working at a steam pressure of 90lb. per square inch. The shell of the boiler is made of mild steel of special quality. The feed water is supplied by an injector of ample capacity, and a donkey pump is also provided for feeding the boiler in case the injector should get out of order. The smoke box is bolted to the cylinders of the engine, and the end of the fire box rests on a strong ash pan which has a door for regulating the draught. The engine is fitted with two cylinders, each 13in. diam. and 18in. stroke. Both cylinders are steam jacketed, and provided with Hartnell's automatic expansion valve gear, whereby great regularity in speed is obtained, even under considerable and frequent variations of load. The crank shaft is made of steel in one piece and without a weld, and on it are placed side by side two heavy fly wheels of 5ft. 8in. diam., running at a speed of 120 revolutions a minute. We understand that the engine is capable of indicating 130 h.p. From the fly wheels are driven two shunt wound dynamos, specially constructed for this work by Messrs. Elwell-Parker, Limited, Wolverhampton, which are capable of supplying forty 10 ampère arc lamps each. These dynamos were running at about 700 revolutions per minute, and appeared to work very smoothly, and with almost entire freedom from sparking at the brushes. A very complete arrangement of switches and resistances, together with a current indicator, are fixed in the engine room. The arc lamps used in this installation are the invention of Messrs. Phillips, Harrison, and Hart, and are very neatly designed. The inventors claim for this new type of lamp, that the regulating apparatus is very simple and not liable to get out of order, and that the light is steady and almost white. The building which formed the main approach to the late Exhibition has been converted into a dining room, promenade, and concert room, which are lighted by two, twelve, and ten arc lamps respectively. The remaining thirty-two arc lamps are distributed in the grounds, and are fixed to masts. The wires are carried in a very neat manner from pole to pole, and are hardly perceptible. On the whole, the installation worked very well, the only fault being a humming noise caused by the exhaust steam ascending in a wrought iron chimney, and which was distinctly audible in the concert room. It remains to be seen if this noise will materially interfere with the music. We understand that this arc light installation is the largest the Manchester Edison-Swan Company have as yet erected, their specialty being incandescent lighting; but that in future they are going to devote more attention to arc lighting.

COMBINED ENGINE AND BOILER.

Constructed by Messrs. Marshall, Sons, & Co., Limited, Gainsborough.

General View.

THE LIGHTING ARRANGEMENTS AT THE FORTH BRIDGE.



At a very early stage in the operations connected with the erection of the Forth Bridge, it was felt that, as a large part of the work would be carried on continuously day and night, a very complete lighting plant would be essential. Arrangements were entered into with Messrs. Siemens Brothers for an extensive installation on the south side of the river for the lighting of the engineering shops and yards, and of the offices, stores, &c., the former by arc and the latter by incandescent lamps. This installation, which has recently been considerably extended, consists of three Siemens compound dynamos, each wound for an output of 120 ampères at 110 volts, two for 60 ampères at same e.m.f., and five for 15 ampères at 300 volts; there is also a Crompton series machine of a new type for 15 ampères at 1200 volts. The engines are by Messrs. Davey Paxman & Co., of Colchester. They are of the horizontal non-condensing type, and with 60lb. steam pressure indicate 120 h.p.

The two large engineering shops for bending, drilling, and planing the steel plates used in the construction of the bridge are each lighted by twenty-two Siemens differential arc lamps, with triple carbons. They are coupled in parallel circuits of two in series. The e.m.f. between the mains is 110 volts, and a small German silver resistance is placed in circuit with each pair of lamps, to reduce the current to 10 ampères. The moulding loft and the yards are lighted by arc lamps of a similar type. These are coupled in series circuits of six lamps, each circuit being supplied by a separate dynamo. The general offices, drawing offices, and stores are lighted by three hundred 16 c.p. incandescent lamps. Messrs. Crompton and Co. secured the contracts for the smaller installations on the north side of the river, and on the island of Inchgarvie. These consisted at each place of two Crompton-Burgin dynamos, one for six arcs and the other for sixty incandescents. The arc lamps were of the D.D. type, and were hung on poles in the yards, and the incandescent lamps were principally used in the time offices, stores, &c. The dynamos were driven by simple horizontal steam engines. During the sinking of the foundations, the caisson work was greatly facilitated by the electric lamps. Their portability and independence of atmospheric variations rendered them invaluable to those who, with such notable intrepidity and success, carried out the extensive excavations in the bed of the river. On the completion of the foundation and commencement of the superstructure, a complete re-arrangement of the lighting plant on the erection became necessary. On the Queensferry side, extra dynamos for incandescent lighting were laid down, and a high tension machine for arc lighting. Underground conductors had been used extensively for the distribution of the current through the works. These were cables, insulated with gutta-percha and jute, with a sheathing of steel wires, and an external serving of jute and compound. They had been three years underground, and had all become more or less defective. They were therefore replaced by overhead wires, and moved after repair down to the superstructure, where their steel sheathing forms a great protection against accidental contact with plates, &c., and where the demand for insulation is not so high, owing to the possibility of running them almost exclusively along timber stagings. On the north side of the river a complete new generating station has recently been erected, with a 70 i.h.p. horizontal engine, two 14 arc light Crompton-Burgin dynamos, and two Crompton compound machines, each for eighty incandescent lamps. On Inchgarvie an exact duplicate of the existing plant and a Siemens 6 arc lighter has now been added. There are thirty arc lamps on each of the main cantilever erections at South Queensferry, Inchgarvie, and North Queensferry. The lamps are principally by Crompton and Siemens. The remarkable simplicity and strength of the D.D. type of the former maker render it singularly adaptable to work of this class. The circuits are run from one elevated staging to another by means of flexible cables tied to hemp ropes, and the current is led by overhead circuits from the generating stations to terminal houses, from which it is distributed to the various working points. Groups of lamps in series with other groups are provided with automatic cut-outs and equivalent resistances, to isolate the effects of accidents to the conductors. The lamps are suspended from light poles lashed to the girders, or are swung between guide wires on the wind bracing.

While the advantages of portability and economy render the arc lamp very adaptable to temporary engineering operations, the glaring nature of the light and the sharp intensity of its shadows are disadvantages which have been very forcibly demonstrated at the Forth Bridge works. In the engineering shops, although the distribution of the light has been most carefully studied, chipping, planing, drilling, &c., have only been carried on at night by the aid of myriads of hand lamps, and on the erection small and lofty stagings, dependent for light on arcs at some little distance, are thrown into total darkness by the shadow from a passing plate, or some small object interposed between them and the minute source of light. It was while combatting these difficulties with more or less success, that the "Lucigen" light came to the aid of the builders of the bridge. This light was described in *Industries*, Vol. I., page 125, and its earliest and most extensive application has been at these works. Fig. 1 shows a section of the burner, and Figs. 2, 3, 4, and 5 some recent modifications in the form of the combustion chamber and valves. At the works in South Queensferry, where the largest number of Lucigens are employed, an engine, air compressor, and receiver are stationed in the electric engine room, shown in Fig. 6. The air pressure at the engine room is 20lb. per square inch, and is distributed over the works by an extensive system of pipes. Moisture accumulates, owing to the varying temperature of the air, and suitable drain cocks are therefore provided at the low levels. The lamps are usually placed on trestles about 12ft. high, and the oil forced into their tanks from the foot of the trestles by the air pressure. Considerable labour is involved in carrying the oil to the numerous lamps; but in permanent installations this might be saved by having a head of oil at the storage tanks, and a system of supply pipes from there to the lamps. Storage is provided at the works at South Queensferry for 50,000 gallons of creosote oil, which is also used for the rivet furnaces described in *Industries*, Vol. III., page 618. The power required for the air pressure for each lamp of 2500 c.p. is about ·25 h.p. A combined steam engine and air compressor of a compact form is used on Inchgarvie for the air supply for the Lucigens on that part of the works. There can be no question of the great superiority of the Lucigen over arc lamps for many purposes; but intending users of this light should also consider its many serious

Digitized by Google

LIGHTING ARRANGEMENTS AT THE FORTH BRIDGE.

disadvantages. In the matter of cost, the advertising circular of the Lucigen Company states it at 2d. to 3d. per hour for 2500 c.p.; this is exceedingly cheap, and very much cheaper than a long series of experiments with numerous Lucigens has shown to be the cost at the Forth Bridge. The cost, of course, varies according to the facilities for obtaining oil; but as the burner, to enable it to maintain a light of 2500 c.p., must be adjusted for a consumption of from 2¼ to 3 gallons per hour, according to the quality of the oil, and as the lowest price of this commodity in the market just now is 2d. per gallon, the facilities for obtaining oil would require to be very much improved to allow the cost even to approach the price above named. Besides the cost of transit, considerable allowance must be made for waste in the transmission of the oil from the manufacturing works to the consumers. A very small quantity of water in the burner will instantly extinguish the lamp, and one of the most fruitful sources of expense and annoyance with the light is the almost unavoidable presence of water in the oil, for although it may be dispatched from the works apparently quite free from water, after standing some time in the storage tanks, large quantities filter through the oil, and must be periodically strained away. This water is the pest of the neighbourhood; it destroys the gardens which lie along its route to the river, and reaching there, and combining with the kelp, it contrives to provide for the stroller along the shores of the Forth a stench well nigh insupportable. The light is not satisfactory in anything like a strong breeze, and invariably spreads an oil shower of more or less density for 15ft. or 20ft. around it, thus greatly increasing the risk of fire on timber stagings. Another very forcible objection to the light is the noisy roar produced by the air blast, and which renders conversation in its proximity inaudible. While readily granting the great value of this light for certain temporary purposes, those who contemplate any permanent artificial illumination will, of course, hesitate before sacrificing a great deal for a large well diffused glare, even if under exceptional circumstances it may prove economical.

As in the shops the Lucigen to some extent superseded the arc lamp, so it in turn has given place to the new type of large incandescent lamp manufactured by the Sunbeam Company, of Newcastle. These are in use up to 1500 c.p., and give great satisfaction; their absolute steadiness and great diffusive power is so far unrivalled.

While each light has some special adaptability, there is an ample field for them all in the varied and extensive operations in rapid progress over the estuary of the Forth, and on dark evenings a remarkable spectacle is presented when the busy scene is illuminated by the brilliant lights, which cast beautiful reflections into the water from their lofty positions on the great structure.

THE REVOLUTION IN COTTON DYEING.

There is, perhaps, no old established industry which has been so completely revolutionised by the results of modern scientific investigation as that of dyeing and calico printing. Although dyers, as a rule, adhere very strictly to what they are pleased to call the "good old processes," they have been gradually led to adopt, in some cases even without being themselves aware of it, the new and much more effective though simpler modes of manipulation suggested by a clearer insight into the chemistry of dyeing. Still we have, until quite recently, considered it as an unchangeable truth that animal and vegetable fibres require perfectly different treatments, owing to their vast difference in chemical composition; and that the former, being composed of albuminoid matter, will generally combine with dye stuffs without the intervention of a mordant, whilst the latter, which consist of cellulose in a greater or lesser state of purity, always require the intervention of a mordant in order to combine with dye stuffs. But even this fundamental fact has been overthrown quite lately by the introduction of a new class of colouring matters, which have very inappropriately received the name of "substantive dyes," and which will dye cotton and other vegetable fibres in exactly the same manner as the old colouring matters dye silk. It is this new and important discovery of which we intend to give a brief account.

It is well known that cotton is the cheapest and by far the most important fibre. Its annual production exceeds several times that of all the other fibres combined. The great purity of raw cotton—which contains from 90 to 95 per cent. of pure fibre, whilst crude silk contains only 70 to 75 per cent. of pure silk, and crude wool only 30 to 35 per cent. of the pure fibre—and the consequent ease with which it may be spun and woven, make cotton goods so cheap that cotton is essentially the fibre for the million. The dyeing of cotton was, however, until now much more expensive than that of wool. As none of the dye stuffs used hitherto would combine with cotton without the preliminary process of mordanting, cotton dyeing required not only more materials, but also a greater amount of manipulation and care, in order to be successfully accomplished. It was only by using a great deal of machinery, and by treating very large quantities of material at the same time, that these drawbacks could to some extent be compensated. But there was still another great drawback which remained. Dyed wool, being a combination of the wool itself with the dye stuff, is, as a rule, a fairly stable compound, resisting the action of atmospheric influences, washing, &c., well enough. Dyed cotton, on the contrary, being a treble compound of fibre, mordant, and dye stuff, is much more subject to deterioration. There are, of course, exceptions, such as turkey red, alizarine blue, or aniline black, which stand any amount of soaping and exposure to light without

LIGHTING ARRANGEMENTS AT THE FORTH BRIDGE.

(For description see page 599.)

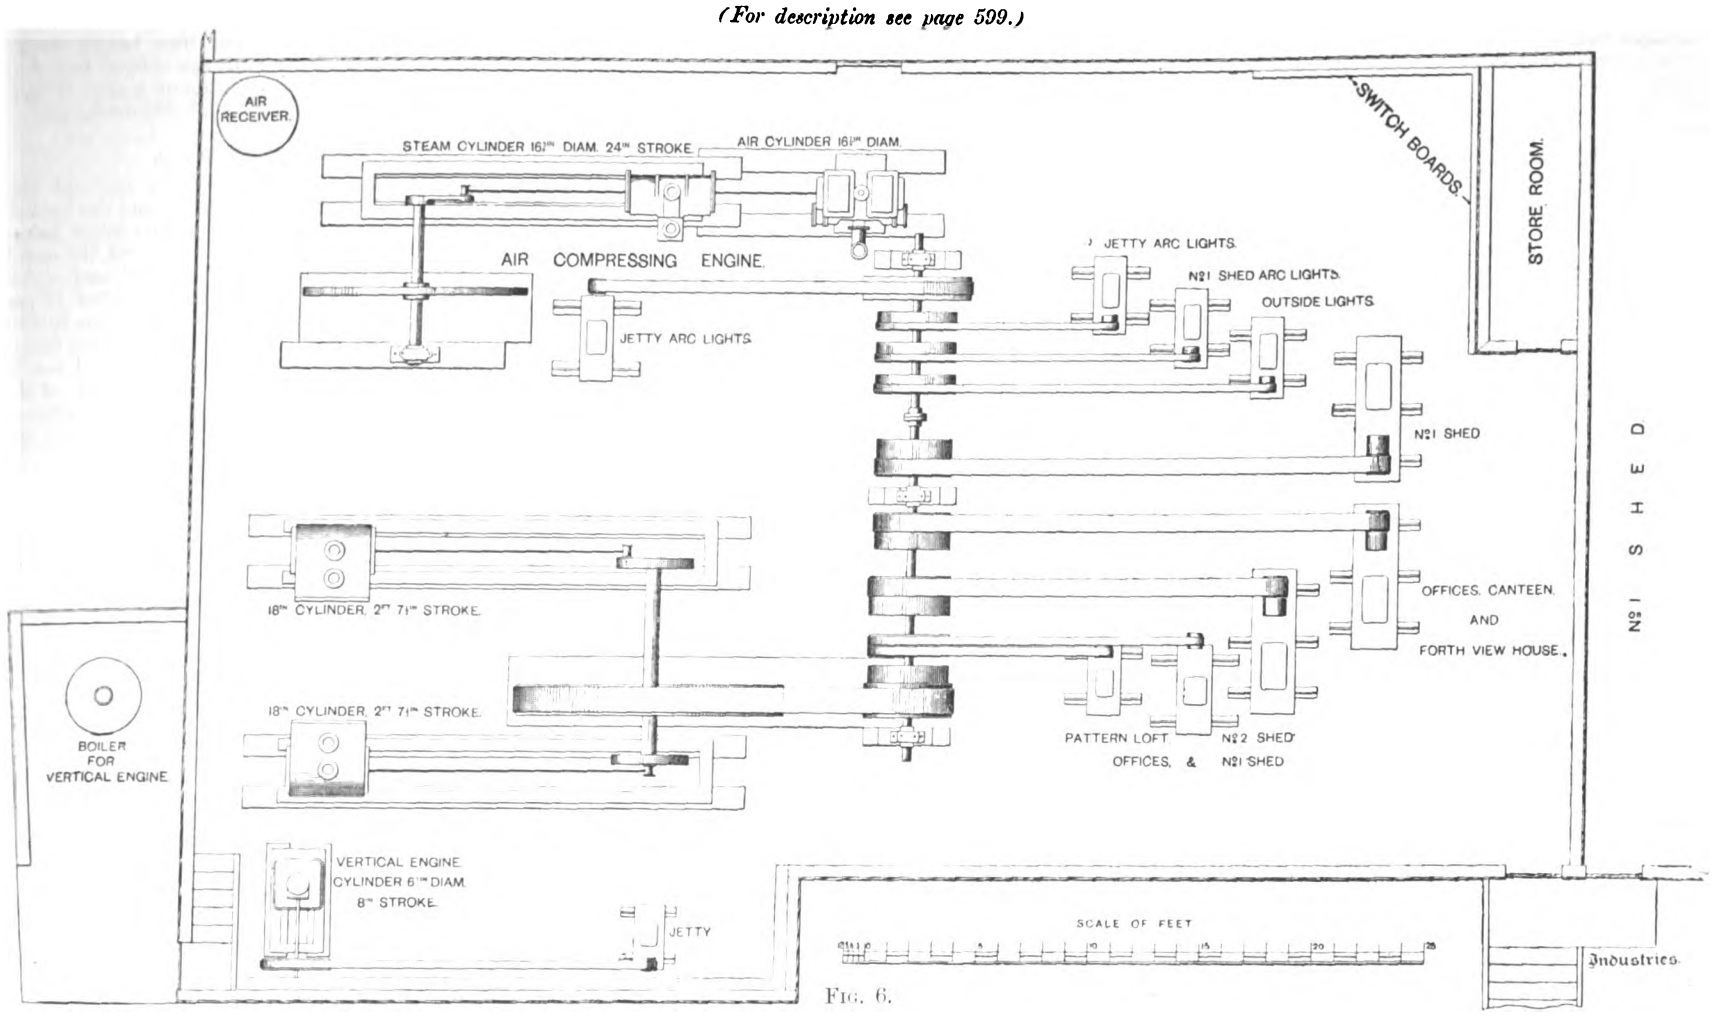

FIG. 6.

deterioration. But these exceptionally fast shades are very expensive to produce, whilst the majority of cheap cotton colours are decidedly fugitive. Most of them stand light fairly well; but they will not stand soaping, which is a very serious drawback, interfering with the cleanliness and health of the lower classes, for whose use cotton goods are chiefly intended.

All these difficulties are removed by the new "substantive" dye stuffs, which, far from being deteriorated by soaping, even require the use of soap or other alkaline mediums in the process of dyeing. These dye stuffs simplify the process of dyeing in an astonishing manner. It is sufficient to prepare a boiling aqueous solution of the dye, to add some soap or soda to it, and to immerse the cotton goods, in order to obtain a perfectly fast shade of any required depth. The soap or soda does not act as a mordant; it only facilitates the combination of the dye with the fibre. It is quite obvious that an agent which has been instrumental in producing the shade on the fibre will not detract from it when afterwards brought into contact with it; and, therefore, goods dyed with "substantive" colours will stand any amount of subsequent washing and scouring without losing their brilliancy of shade.

All "substantive" dye stuffs, of which there exist a very large number, belong to one group of colouring matters, viz., the group known as "azo dyes." This group, the first representatives of which were brought out in 1875, proved the most fertile of all. After having yielded hundreds of colouring matters chiefly adapted for wool dyeing, it has also produced these new substantive dye stuffs, the first of which was discovered, accidentally, in 1884. This substance, which received the name of "congo red," was produced by acting with tetrazo-diphenyl chloride on naphthionic acid. It might have remained unnoticed, as it has no unusual chemical reactions, and, as a wool dye, offers no special advantages. A lucky accident, however, disclosed its power of dyeing unmordanted cotton from an alkaline dye bath, and to this peculiarity congo red owes its unparalleled success as a chemical product. Very soon it was discovered that congo red was only a representative of a very numerous class of substances, and that its peculiar and valuable property was shared by all azo dyes derived from diphenyl and all homologous and analogous substances. It is not our intention to go at any length into a discussion of the composition of substantive azo dyes, as this would necessarily carry us into theoretical chemistry; but we may briefly state that a great variety of substantive azo dyes may be prepared, comprising in shade all the range from yellow through scarlet, red, and violet into deep blue; and also that a certain law has been discovered which regulates the properties of these dyes. This law may be condensed in the following words: All azo dyes are made up of two parts, which, being brought together, combine to form the molecule of the dye stuff. Of these, one enters the reaction in the shape of a diazo (or tetrazo) compound, whilst the other is present in the shape of an amine or phenol. Now, in the case of substantive dyes it has been recognised that the property of dyeing unmordanted cotton merely depends upon the tetrazo compound used, whilst the shade of the dye is dependent upon the amine or phenol combined with this tetrazo compound. Knowing this, we may by judicial selection of the ingredients produce substantive dyes of any required shade, with the only exception of green and clear blue—shades which do not seem to be consistent with azo colours of any description.

The property of combining with unmordanted cotton is inherent in the diphenyl derivatives, which are employed in the preparation of substantive azo dyes. Benzidine (the raw product from which tetrazo diphenyl chloride is prepared), though itself a colourless substance, seems to be able to be attracted from its solution by cellulose and to form a combination with it, which may, by being treated with nitrous acid, be transformed into a tetrazo compound. If cotton, thus treated, be immersed into a solution of sodic naphthionate, congo red is formed on the fibre. This reaction, however imperfect, forms the starting point for a new departure of quite recent date, which may be considered as a very interesting development of the chemistry of substantive azo dyes. Mr. A. R. Green, an English chemist, has succeeded in preparing a compound of distinctly yellow shade, called "primuline," which, although a primary base and not an azo compound, possesses in a much higher degree than benzidine the property of combining with the cellulose of cotton. This fibre, on being treated with primuline, may be dyed any desired shade of yellow; and this yellow cotton, or, chemically speaking, this combination of cotton with primuline, may afterwards be treated exactly like a primary base. It may be diazotised by being brought into contact with nitrous acid. This diazotised primuline cotton may now be dyed any shade by simple immersion into a solution of any amine or phenol, and thus a variety of shades is produced, which, from the fact of their having been formed on the fibre itself, have received the name of "ingrain" colours. Unfortunately, from a scientific point of view, the inventor has not disclosed the composition of his "primuline," and thus it is at present impossible to foretell the doubtlessly interesting consequences of his discovery.

Returning to the practical results of the introduction of substantive dyes, there are still a few points to be discussed. It has already been explained how, by the discovery of these dyes, we have come into the possession of a means of producing cheap and fast shades on cotton goods. Another useful application is furnished by the fact that by their use we are enabled to introduce cotton into woollen goods intended for "milling." The process of milling, so much used in the production of heavy woollen goods, tweeds, &c., consists in saturating the goods with strong solutions of soap, to which soda is added sometimes, and then submitting them to a violent kneading in the milling machine. Of course, goods which are to be milled must be dyed with colouring matters which are not in the least affected by soap and alkaline reagents. Even for wool, very few colouring matters possess the required properties, and it has always been considered impossible to subject mixed goods—produced from wool and cotton—to this process. Now, by using cotton dyed with substantive dyes, this difficulty is overcome, and we may thus produce milled goods which, if the proportion of cotton be kept within reasonable limits, are just as good, but much cheaper, than those made of pure wool. The wool itself, if intended to be milled, is now frequently dyed with substantive dyes, because they are less liable to "bleed" in the operation of milling than the shades produced by the old dye stuffs. It is especially for all uses connected with milling that Green's ingrain colours are particularly valuable, because in them the tendency to "bleed" is reduced to a minimum.

The introduction of substantive dyes into the market has met with unparalleled success, and although of comparatively recent date, the demand for them is enormous and ever increasing. It may be assumed that by and bye, as they cover more and more the range of all the shades required by the dyer, they will supersede, in cotton dyeing, all other dyeing materials. The early aniline dyes, which have triumphantly replaced, only a few years ago, the old fashioned dyeing materials of past centuries, will have to retire into a more modest range of application, and to give up part of the field they have conquered to their new competitors, the "substantive" dyes.

STANDARDS OF LIGHT

At the meeting of the Society of Chemical Industry, recently held at Burlington House, Mr. W. J. Dibdin read a paper entitled "Standards of Light," in which he gave the results of a number of experiments made by many observers, which results had been compared with each other. He used a Sugg photometer; the room in which it was employed was kept at a constant temperature by means of a modified mercury thermostat set to 60°F. Pentane, as suggested by Mr. V. Harcourt, was considered the most trustworthy light-giving agent, and experiments had been tried with a mixture of air and pentane, burnt at the rate of 2½ft. per hour, and giving the light of one average standard candle. He had also tried the Methven screen, in conjunction with a flame from coal gas charged with pentane; the slot was arranged to transmit a light equal to that of two standard candles, and the arrangement worked well. The 10-candle test devised by Mr. Sugg was also tried. The top of the argand flame was cut off from view by a screen, so that the lengthening or shortening of the flame did not cause sensible variations in the amount of light used. With this arrangement Mr. Dibdin employed air charged with pentane; and found that the flame might be lengthened or shortened 2in. without making any difference in the amount of light passing under the screen.

He then introduced to the notice of the meeting one of the little pear oil lamps, now so popular on the Continent. The burner consists merely of a tube, in which the height of the wick is regulated by a screw, as in some cheap hand lamps in common household use. The wick is not consumed, and does not project above the level of the top of the tube. A little rod on the lamp holds a short horizontal arm of platinum wire at a given distance above the burner, and the length of the flame is so adjusted that its point just touches the platinum wire. The combustible used is acetate of amyl, better known as pear oil, and is selected because of its constant composition. In the photometrical tests, the flame of this lamp came out so well that Mr. Dibdin was for some time inclined to recommend it as the best of all the standards of light; but the colour of the flame is too orange when compared with the whiter light of the other standards. The extra yellowness at first prevented some of the observers taking accurate readings, but this difficulty was overcome after a little practice. No other objection than yellowness of flame could be brought against the pear oil lamp, which, for simplicity and accuracy, was all that could be desired. He had not been able to obtain one of the incandescent platinum standards, but had experimented with a lamp in which the light was given by incandescent platinum. It consisted of a vertical plate of brass with a hole in it; behind this was a steatite screen, also with a hole in it, and behind this again was a movable strip of platinum foil, and behind the foil an oxyhydrogen blow pipe. In use, the instrument was viewed from the front, while the blow pipe flame was brought into play at the back, and at the temperature of melting platinum it pierced the foil. Mr. Dibdin said that this instrument was very simple, and was theoretically correct, but that after numerous trials he had had to abandon it for the present, because of the uncertainty of equally heating the whole surface of the platinum opposite to the aperture, also because of the buckling of the foil from rapid heating and cooling. These causes produced objectionable variations in the light emitted. All the standards of which he had spoken, the methyl acetate flame excepted, gave virtually the same spectrum, so far as practical purposes were concerned.

In testing by standard candles, variations in results were sometimes due to changes in the temperature of the testing room; but even when the temperature remained the same, candles were generally untrustworthy. They were not made of pure sperm, wax being added to "break the grain." He thought the best of the standards of light to be produced by the pentane air gas flame of Mr. Vernon Harcourt, but Sugg's 10-candle test gave wonderfully constant results.

In the discussion, Mr. Harris expressed himself in favour of a 16-candle standard, sixteen candles being the illuminating power of London gas, and in photometric work it was advantageous to have the conditions as much as possible equal on both sides of the central disc. Several other speakers addressed the meeting. One of them said that standard candles are often not made from the sperm oil of the whale of the southern seas, but from the oil of the bottle-nosed whale of the northern seas, and that the latter oil is less luminous. Another speaker said that the variations depended more upon the wicks of the candles, which sometimes contained visible little particles of borax; in fact, an examiner could buy candles which will make the same gas indicate a luminosity of 16 or 18 candles, as he may choose beforehand. He did not see how the purity of various samples of pentane was to be readily ascertained, and thought that examiners should not be allowed to make their own standard gas. A third speaker believed that there were objections on geometrical grounds to the Methven screen, when used at shifting distances from the screen of a Bunsen's photometer; the principle of a cylinder of flame screened at the top was better. Another speaker remarked that a 3in. flame from pentane vapour will give identically the same light, whatever may be the illuminating power of the coal gas passed over the pentane; even if pure hydrogen be used, the light is the same.

Notes.

ITALIAN SHIPBUILDING.

There appears to be great activity in the building of torpedo boats for the Italian Government. In a report by the British Consul at Genoa, he states that in his district Messrs. Ansaldo & Co., of Sampierdarena, have eight sea-going torpedo boats on hand, which will all be completed by the end of the year. Messrs. Odero & Co. have eight boats, and Messrs. Cravero & Co. four boats in construction. The first named firm has also lately launched a tugboat, and has two others on the stocks, besides a large floating crane and several mud hoppers and barges.

THE BOARD OF TRADE RETURNS.

Last month's Board of Trade returns are very favourable, the exports amounting to £19,276,225, as compared with £16,497,836 in the same month of last year, an increase of £2,778,389. Almost all the leading articles of export show an improvement. Machinery and mill work has increased in value by 32 per cent., hardware and cutlery by 21 per cent., cotton yarn by 20 per cent., and cotton piece goods by 21 per cent. Woollens and worsteds also show increases; and iron and steel, though less in quantity, are higher in value. The imports amounted to £30,370,775, as compared with £27,921,321 in the same month last year, being an increase of £2,449,454. A notable feature is the very large increase in the imports of copper ore and regulus, which amounts to 48 per cent. in quantity and 149 per cent. in value.

THE OWENS COLLEGE.

The occasion of the opening of the new buildings at Owens College, Manchester, was celebrated on the 8th inst. by a conversazione, which was attended by a large and distinguished company. Many of our readers will have had the opportunity of inspecting the new buildings when the British Association made use of them as their head quarters last autumn. The ground floor is occupied by the geological and mineralogical museums, and the botanical and zoological lecture theatres; while the first and second floors are taken up with geological museums and an extensive suite of zoological, botanical, and geological laboratories. The rooms have been arranged so as to obtain the greatest possible amount of light, which is so necessary in laboratories and museums. Apart from the main blocks of buildings is the new Whitworth Engineering Laboratory, which has been in full operation for about six months. No expense has been spared in making this important department a success, for there are few establishments of the kind in England which have such a complete collection of machine tools of the most approved patterns. As well as these tools, there is an experimental engine, which can be supplied with steam at an initial pressure of 200lb. per square inch, and a 100-ton testing machine. The whole of the new buildings have cost £80,000, and have been designed by Mr. Alfred Waterhouse, R.A., the architect to the College.

A NEW DREDGER.

The members of the Engineering Society of University College, Bristol, recently spent a day on a new dredger which has been built by Messrs. Simons & Co., of Renfrew, and respecting which the Secretary of the Society sends us the following particulars. The dredger, which is of steel, was constructed to the plans of Mr. Girdlestone, the engineer of the Bristol Docks. It is 225ft. long and 45ft. broad, and draws 14ft. 6in. when fully laden. The dredging is performed in the usual way by buckets having a capacity of 1 ton; these revolve round tumblers, which are worked by the same engines which propel the vessel when she is under way. The buckets combined deliver from 17 tons to 19 tons per minute. The hopper capacity is from 1000 tons to 1200 tons, mainly depending on the nature of the dredgings. When the vessel is fully laden, the bucket ladder is raised by a crane at the stern. The vessel then steams out to sea at a speed of about ten knots an hour. The propulsion is effected by two triple expansion engines of 1600 i.h.p. Each of the engines works a screw fore and aft. Thus there are four screws altogether, each having a diameter of 8ft. 2in. The process of discharging the material is very speedy. The vessel may be going along at nine knots, when on a given signal the engines slow down, and the whole 1000 tons of spoil are discharged in the space of a minute. The doors can be drawn up and the dredger steaming back again at full speed in eight minutes from the first signal. The four screws enable her to travel ahead or astern with equal facility, and to turn in her own length when required. Thus while all large craft are obliged to make use of tugs to navigate the very sinuous course of the Avon, the dredger is independent of all extraneous aid.

MACHINERY IN MEXICO.

Great Britain supplies about 50 per cent. of the total imports of machinery at Vera Cruz, and the United States 30 per cent., a large portion of the latter being light machinery, such as sewing machines. Of the metal goods imported, France and Germany furnish each about 30 per cent., whilst Great Britain only supplies 18 per cent., and the United States 15 per cent. The British Consul at Vera Cruz states that this is due to the efforts of the French and German representatives, and not to the dearness of British goods. A large portion of the American metal goods imported consists of "notions," ingenious trifles which are chiefly machine made, and therefore cheap.

STRIKES IN THE UNITED STATES.

Sir L. S. Sackville West has drawn up a report on the labour strikes which occurred last year in the United States, but does not vouch for the statistics being completely accurate, as the Government have not yet published their report on the subject. According to the information thus far available, there were during the year 1000 strikes, in which 400,000 men were engaged. More than two-thirds of the strikes between January and July, 1887, were fruitless, and only brought loss and suffering to those engaged in them. Of successful strikes in the latter half of 1887 were those of the iron workers at Pittsburgh, Yaingtown, and Hocking Valley. As a whole about 38 per cent., or something more than one-third of the strikers in 1887, succeeded in getting their demands, as against 20 per cent. in 1886. It is calculated that nearly 10,000,000 days' work and wages were lost. About 3 per cent. of all the strikes in 1887 were for peculiar causes difficult to classify. The rest may be grouped under three causes: (1) Demand for fewer hours' work or higher wages, 542 strikes; (2) trades union demands other than wages and hours, 225 strikes; (3) sympathetic strikes, 68. The total loss in wages is estimated at £2,700,000, besides the indirect injury to trade. Sir L. West states that the chief feature of the strikes has been the development of combinations among employers, not only among those in the same line of business and in the same locality, but among those widely separated and engaged in different trades. The employers are now using the same weapons against the workmen as the workmen have used against them.

BRITISH SHIPS AND GUNS.

Admiral Lord Alcester, in speaking at the national defence meeting held recently in the City, gave utterance to some remarks which are of a nature not at all calculated to please British shipbuilders and gun makers. He asserted that we were far behind our opposite neighbours, not only in the quantity but in the quality of our cruisers, and in the quantity of our modern guns; though he fully recognised all that had been done lately to remedy that defect. The Admiral is further reported to have said that "if they could not construct vessels which would, when fitted for sea, have their armoured belts above water, and could stow their crews, let them go to the private yards in France to supply them with the lines of vessels that could. The two latest additions to the French navy, the 'Tage' and the 'Cecille,' were the most dangerous vessels to an enemy's commerce that had ever been launched, and there were three more building; but he did not believe that there was any want of talent in the shipbuilders of this country. With reference to the guns, he believed that if orders were given in time they might yet retrieve their position; but if they could not do so otherwise, let them try whether the gun foundries of Sweden, always a friendly Power, whose steel was proverbial for its excellence, could not provide them with our most urgent wants." It will be noticed that Lord Alcester has qualified his statements with a number of "ifs" and "buts." At the same time it is difficult to discover what good purpose can be served by such a course of argument. At a time when vacant slips are to be found in the principal yards of the leading shipbuilding country in the world, it is preposterous to speak of our Government going abroad for their requirements. Our own shipbuilders are better qualified than any others to supply satisfactory vessels, and any faults which exist in the war ships in the navy constructed by private firms are due not to incapacity on the part of the builders, but to faulty designs on the part of the Admiralty. There is also no reason why we should not be able to turn out all the heavy guns we require ourselves.

Patent Record.

Compiled from "The Official Journal of the Patent Office," by W. E. Heys, *70, Market-street, Manchester.*

APPLICATIONS FOR PATENTS.

(The names in italics within parentheses are those of Communicators of Inventions.)

ENGINEERING.

1st June, 1888.

8002. Groth, L. A..... Ships (*Monnot*).
8009. Nelson, A. S..... Hydrocarbon engines.
8010. Mills, E. C. ..... Indicators for steam engines.
8012. Siddell, G. ..... Rotating large forgings while under the steam hammer.
8013. Fontaine, F..... Sewing machines.
8015. Ferguson, J. W..... Indicating the over-heating of bearings.
8018. Combe, A..... Twisting frames.
8019. Sutcliffe & Lindley... Speed regulation.
8022. Reid, D. McI. ..... Lifeboats.
8023. Gilbey & Simpson ..... Automatically compensating for expansion and contraction in railway signal wires.
8024. Gundelach, L..... Sewing machines.
8028. Ansell, R..... Friction lifts.
8031. Ellis, W..... Machinery for cutting wood for matches, splints, and match boxes.
8042. Seale, E. A..... Vehicle wheels.
8050. Hill & Gillmore ..... Small arms.
8052. Redfern, G. F. ..... Centrifugal machines for use in the manufacture of sugar (*Abell*).
8053. Fletcher, G. ..... Evaporating pans (*Brocklehurst*).
8055. Harfield, W. H..... Apparatus for working chain cables.
8061. Watts, J. W. ..... Knitting machines.
8064. Scott, F. W..... Tubular vacuum pans (*Freitag*).
8066. Wells, C. ..... Oil engine.
8069. Seck, H..... Bolting machines.

4th June, 1888.

8074. Roe, J. P. ..... Transporting loads by ropes.
8080. Gullery, J. ..... Washing and mangling machine.
8088. Henshall, W. ..... Rotary motor (*Ward*).
8095. Thwaite, B. H. ..... Solid steel castings.
8096. Bastow, A. ..... Indicator for pumps.
8104. Belton & Lowe ..... Warp lace machines.
8105. Cochrane, W. ..... Weaving fur pile fabrics.
8106. Landye, J..... Railway and tramway vehicles.
8107. Scott, J. R. ..... Feed water heaters.
8113. Morison, D. B..... Pistons for steam indicators.
8114. Bohm, W. D..... Grinding machinery.
8119. Hett, C. L. ..... Centrifugal pumps.
8124. Sautoy, C. S. du ..... Steam traps.
8127. Vyrazil, F. ..... Evaporating, distilling, or condensing apparatus.
8128. Robin, A. H..... Furnace grates.
8136. Backman, P. G. ..... Lift.
8137. Durham & Shaw..... Lubricating bearings.
8138. Park, R. P. ..... Overhead gear.
8143. Myers, F. ..... Type writing machines.
8151. Heeson & Rogers ..... Furnace grates.
8152. Holman & Holman..... Drilling rocks.
8153. Bougouin, L. P. ..... Anti-friction bearings.
8156. Ostolaza, E. A. y ..... An improved motor.
8163. Carpenter, A. H..... Feathering blades of paddle wheels.
8167. Standfield, J..... Lifts.

5th June, 1888.

8174. Fairweather, W. ..... Fringing machines.
8176. Cardwell & Watson... Rail chairs and couplings for permanent ways.
8178. Scott & Carroll ..... Machines for the formation of matrixes for stereotype plates.
8184. Shilton, A. J. ..... Making copper tubes.
8187. Baxter & Macdougald Removal of cotton lint from seed.
8191. Thomson & Thomson... Knife blade for reaping machines.
8194. Hulse, W. W. ..... Drilling, boring, and milling metals.
8204. Peters, G. M. ..... Cartridge loading machines.
8207. Seifert, O. ..... Rotary pumps.
8210. Boult, A. J. ..... Steam engines (*Mesia*).
8211. Thompson, W. P..... Steam engines (*Austin*).
8212. Errock & Kenworthy. Mules.
8213. Derriey, J. ..... Printing machines.
8215. Stokes, P. S..... Improved rasp and rasp punching machine.
8222. Cooper, W. ..... Designing slide valves.
8228. Johnson, J. Y..... Railway signals (*Koyl*).
8231. Newton, H. E..... Embroidery machines (*Ricter and Co.*).
8233. Pitt, S. ..... Cylinder welding apparatus (*Rowland, Hill, & McLachlan*).
8234. Pitt, S. ..... Welding furnaces (*Rowland, Hill, and McLachlan*).
8235. Nordenfelt, T. ..... Machine guns.
8236. Nordenfelt, T. ..... Range finders.

6th June, 1888.

8241. Carmont, W. E. ..... Road vehicles.
8243. Randall, C. A. ..... Indicators for vehicles.
8247. Berry, B., & others..... Self lubricating loose pulleys.
8249. Ashton, F. ..... Valves and ball boxes of hydrants.
8252. Johnston, G. ..... Gas motors.
8253. Wroe, J. ..... Grooving and key seating wheels.
8254. Page, J..... Breech-loading small arms.
8255. Bever, A. ..... Friction clutches.
8257. Leeming, J. A..... Spinning machinery.
8259. Hartley & White ..... Multiple hydraulic motor.
8267. Barth, G. A. ..... Steam engines.
8268. Wakefield & Worth. Mitreing apparatus.
8273. Kosztovits, O..... Gas engines.
8276. Lock, C..... Couplings for railway vehicles.
8278. Freeman, J. K., & others Car coupling.
8280. Miller & Wright ..... Thill couplings.
8286. Reinhold, C. ..... Bending metal rails (*Schrabetz*).
8293. Haddan, H. J. ..... Propellers and rudders (*Hofmann*).
8297. Edwards, E..... Tuyeres for forges (*Giraud and Guillemin*).
8300. Delamare-Debouttéville & Malandin... Starting gear for gas engines.
8304. Fraser, J..... Hydraulic machinery.

7th June, 1888.

8308. Warrington, W..... Dobbies.
8315. Ingham, W. P. ..... Pressure gauges.
8316. Anderson, J..... Planing machines.
8317. Altmann, A..... Petroleum motors.
8318. Baird, R. ..... Steam boilers.
8321. Rapier, R. C. ..... Machinery for the relief of chain cables exposed to sudden strains.
8322. Hustler, J..... Working the fallers of fulling stocks.
8326. Henderson, T..... Slide valve.
8328. Haslam, L. ..... Manufacture of cellular cloths.
8329. Prott & Seelhoff..... Hydraulic accumulators.
8331. Tornell, F..... Revolvers.
8337. Brendel, P. L..... Propelling vehicles.
8340. McDowell, D..... Blast pipes for locomotive engines
8343. Vonhof, P. ..... Hoisting engines.
8345. Vonhof, P. ..... Brakes for regulating the speed of descending loads.
8346. Vonhof, P. ..... Safety catches for cages or corves
8349. Okes, J. C. R. ..... Duplex pumping engines.
8350. Stirling, A..... Steam boilers.
8353. Heathorn, T. B..... Steering and propelling boats.
8356. Mourey, H. ..... Ring spinning machines.
8365. Downing, G..... Manufacturing buttons (*Arnold*).

ELECTRICITY.

1st June, 1888.

8039. Le Clercq & Vansteenkiste ..... Conversion of electric currents.
8062. Kleiner, F. ..... Electrical time switch and electrometer.

4th June, 1888.

8081. Rowbotham & Fox..... Electrical bells.
8099. Crompton, R. E. B., and others..... Electrical hoists or cranes.
8161. Nichols, C. C..... Bleaching paper pulp by electricity.

5th June, 1888.

8170. Allison, H. J. ..... Governing electric motors (*The Baxter Electric Manufacturing and Motor Co.*).
8171. Ghegan, J. J. ..... Magneto-electric liquid level indicators.
8200. Goolden & Ravenshaw Electrical transformers.

CHEMISTRY.

1st June, 1888.

8017. Thomson, W..... Antiseptic substances.
8030. Purvis, F. A..... Separating gold (*Trimble*).

4th June, 1888.

8072. Nicholas, J..... Explosives.
8110-11-12. Abel, C. D..... Manufacture of maltose from potatoes (*Kiderlen, Von Leenhoff, Wernicke, Wilhelmi, and Köhlmann*).
8116. Wilson, E. ..... Curing malt and hops.
8157. Dickson & Clark ..... Ores of copper.
8160. Andreoli, E. M. H..... Chlorine and its oxygenated compounds.

5th June, 1888.

8177. McCulloch, J., & others Obtaining silica and alumina.
8208. Leffmann, H. ..... Carbonic acid and magnesia.
8223. Reed, A. H. ..... Eliminating iron from ores (*Conkling*).

6th June, 1888.

8250. Heys, W. E. ..... Dyeing with aniline black (*Marchal, Falck, et Cie*).
8303. Donkin, W. F. ..... Amalgamation of gold (*Donkin*).

7th June, 1888.

8332. Thompson, W. P..... Extraction of gold and silver from ores (*Julian*).
8351. Page, G. S..... Anhydrous liquid ammonia.
8354. Leclanché, M..... Depolarisers for batteries.
8366. Jeyes, J..... Soap.
8369. Gerson, E. ..... Chemical tanning.

MISCELLANEOUS.

1st June, 1888.

8003. Langstaffe & Peckover ..... Purifying water and preventing incrustation.
8008. Wise & Hopkins ..... Finishing tin plates.
8014. Booth, J. H..... Horseshoes.
8020. Turner, S. ..... Roof tile.
8021. Rawlings & Rawlings Soldering apparatus.
8025. Turner, H. W..... Spanners and pipe wrenches.
8027. Mitchell, C. T. ..... Thermometers.
8034. Harvey, W. ..... Soldering irons.
8035. Jones & Read ..... Extinguishers for lamps.
8036. Lewis, E. J. ..... Velocipedes.
8037. Johnson, J. C..... Socket pipes for conveying liquids and gases.
8038. Higginbottom, J. ..... Separation of dust.
8041. Stahl, J. A. ..... Fire escapes.
8043. Edwards, J. H. ..... Door latches.
8045. Seligsohn, L. ..... Fancy figured wood plates.
8046. Newton, A. V..... Cartridges (*Nobel*).
8049. Paddock, G..... Replacing broken slates.
8054. Casper & Debnam ..... Dyeing.
8058. Chiozza, L. ..... Air pump.
8059. Lake, H. H. ..... Treating vegetable substances for the production of paper stock (*Manning, Peckham, and Chambers*).
8067. Warrick, F. W. ..... Stoppering bottles.

4th June, 1888.

8070. Morrell, J. C. ..... Dust bins.
8078. Watt, J. ..... Increasing circulation in water during ebullition.
8086. Ballardie, D. ..... Lamps.
8087. Hyman, E..... Velocipedes.
8090. Rylands, R. A..... Grindstones.
8094. Stevens, W. F..... Placing fog signals upon the railway metals.
8100. Bowing & Beckingsale Artificial fuel.
8109. Merkelbach, A. ..... Watches.
8120. Davies, J. ..... Indestructible wick for oil lamps.
8121. Walker, F. ..... Process for obtaining two or more parallel back stitch seams (*Koehler.*)
8125. Stone, R. ..... Driving bands.
8126. Werner, R. ..... Velocipedes.
8129. Parry & Welch ..... Utilisation of slate waste.
8130. Liscoe, G..... Mechanically separating solids from fluids of sewage.
8142. Boult, A. J. ..... Seal locks (*Brown*).
8144. Faulkner, H. ..... Shoes for horses.
8149. Haddan, H. J. ..... Decorticating and cleaning grain (*Wimmer*).
8150. Garcin & Jacquemond. Manufacture of gloves.
8158. Coker, W. H. ..... Metallic fences.

5th June, 1888.

8180. Parker, H. ..... Ornamentation of metals.
8181. Norton & Baker ..... Oil lamps.
8183. Blunt, J. C. ..... Cinder sifters.
8196. Rigg, J., & others ..... Valves and taps.
8203. Gilchrist, R. B. ..... Cork extractors.
8206. Scoville, E. U. ..... Valves.
8214. Mewburn, J. C. ..... Lead and rule holders for compositors (*Low*).
8217. Clark, A. M. ..... Adding machines (*Moore*).
8219. Comstock, W. H..... Bottle filling apparatus.
8221. Rapeaud, N. F. E. ..... Artificial leather.
8224. Nunn, E. B. ..... Cutting hay.
8225. Docwra & Docwra..... Raising broken well boring rods.
8226. Downton, R. L. ..... Dust collectors.
8229. Hart & Baynes ..... Spindles.
8237. Seck, H..... Sifting flour.

6th June, 1888.

8238. Haywood, R. ..... Apparatus for ruling lines.
8245. Anslow, G. ..... Locks and latches.
8256. Jüngst, C..... Cutting clay.
8258. Hookham, G. ..... India-rubber tyres.
8261. Garside, E. ..... Purifying the water used for wool scouring.
8263. Hatfield, W. B. ..... Cutlery.
8270. Ellis, C..... Ventilators.
8277. Abbott & Rowe ..... Automatically extinguishing lamps.
8279. Bruce, W..... Fire escape.
8285. Phillips, L. B..... Nails.
8287. Spannagl, J..... Fire extinguishing apparatus.
8288. Griffin, J. T. ..... Alloys for anti-friction purposes (*Singley*).
8290. Johnson, J. Y..... Separating liquids having different boiling points (*La Société Française des Alcools purs*).
8291. Haddock & Harvey..... Treatment of sewage.
8294. Carstens, A..... Horseshoe nails.
8295. Peet, H..... Extinguishing candles.
8296. Edwards, E..... Door locks (*Aubry*).
8298. Edwards, E..... Hoe (*Pirlot-Prévost*).
8299. Thurlow, Lord ..... Fire extinguishing apparatus.
8305. Mauni, R., Baron de ... Direct propelling spring oar.

7th June, 1888.

8306. Thurlow, Lord ..... Fire extinguishing apparatus.
8307. Barraclough, A..... Metal pipes.
8309. Mulligan, J. ..... Ventilating caps.
8310. Roberts, P. ..... Ventilators on boiler fire doors.
8312. Rose & Vollhard..... Valves.
8313. Walker, P. M..... Ventilation of rooms.
8319. Darling, J. ..... Needle holder.
8320. Haddleton, P..... Cleaning and painting dome ceilings without the aid of scaffolding.
8323. Wells, H..... Screw nails.
8325. Love, J..... Carburetting gas.
8333. Jeyes & Short..... Ornamenting glass ware.
8336. Carver, H. C. ..... Extinguishing fires.
8344. Vonhof, P..... Shaft door closures.
8352. Page, G. S..... Bombs.
8355. Cohen, J. B. ..... Flue cap.
8358. Perriman & Alger..... Straining wire.
8364. Weisshuhn, C..... Manufacture of wood pulp.
8367. Ramsden, W. T. ..... Fire escape.
8371. Edwards, W. ..... Prevention of the pollution of rivers.
8373. Lake, W. R..... Gas burners (*Burrows*).
8374. Merryweather and Jakeman ..... Armoured hose pipe.

COMPLETE SPECIFICATIONS ACCEPTED.

Persons interested in opposing the grant of the following patents may give notice of opposition at any time within two months after the dates given.

ENGINEERING.

9th June, 1888.

8079. Klein, E. ..... Steam regulating contrivances for steam engines.
9133. Hodgson & Tetley..... Weft fork motions of looms.
9513. Fuller, H. E. ..... Nail rolling machines.
9668. Baldry & Pullon ..... Excavators.
9782. Boyle, R. K..... Case hardening of iron or steel.
9809. Reader, R. ..... Sewing machines.
9986. Howell, S. E. ..... Manufacture of tubes for boilers.
10423. Schulhof, J..... Magazine guns.
10621. Dickson, J..... Breech-loading fire arms.
10633. Slater, A..... Buffers for railway vehicles.
10674. Wildman, T., & others... Ring spinning machines.
10737. Wailes, E. F. ..... Stern frames and rudders of ships.
10750. O'Kelly & Collins..... Torpedoes.
10804. Hopps & Bywater ..... Singeing machines for textile fabrics.
10839. Rhodes, G. G., & others Beam engines.
10868. Toussaint, J..... Refining metals.
10873. English, T. ..... Securing rails to metallic sleepers.
10894. Fielden, E..... Weft brake for looms.
10932. Williams, J..... Two-wheeled conveyances.
10976. Hannay, J. B. ..... Furnaces.
11047. Maythorn & Gooday... Four-wheeled vehicles.
11055. Derriman, P. R. ..... Signalling.
11503. Abel, C. D..... Gas engines (*Gas Motoren Fabrik Deutz*).
11687. Gadd, W. ..... Twist lace machinery.
11744. Crook & Ormrod..... Brick making machines.
12041. Thompson, W. P..... Machines for sewing books (*Fifield & Jacobs*).
13177. Appleby, S. ..... Construction of ingot moulds.
13612. Cookson, F. N..... Sewing machine.
17948. Gruhl, A..... Button machinery.
18044. Thomson, J. ..... Combined rotary and reciprocating motion. (Received 5th May, 1888. Ante-dated 12th October, 1887. Under International Convention.)
1028. Carr & Carr ..... Cable grips.
3713. Norton, R. ..... Steam boilers.
4342. Sanderson, R. W. B. ... Feed water purifier (*O'Brien and Weaver*).
4883. Murgatroyd, E..... Wheels.
5469. Brandy, J..... Coupling for railway carriages.
5676. Williams, H. A. ..... Cold rolling metallic rods.
6083. Burdon, L. L. ..... Straightening metallic tools.
6101. Lindheimer, F. O. ..... Crushing mills.
6252. Jefferies, E. A. ..... Locomotive, marine, and other engines.
6549. Holleman, F. A..... Railway brakes.
6574. Daniels, W. H..... Keels for ships' boats.
6599. McConnel & Higginson Grinding the flats of carding engines.
6620. Templeman, G..... Knitting machinery.
6622. Laszgallner&Nöhring Draught regulators in furnaces.
6718. Johnson, J. Y..... Looms (*Moraes*).
6728. Sturm & Schrader..... Machine for wiring bottles.
6788. Walton & Edmeston... Starching machines.

ELECTRICITY.

9th June, 1888.

8240. Hard & Wilson ..... Galvanic batteries.
8701. Ross, J. ..... Electric lighting.
10071. Sayers & Sturge ..... Electric incandescence lamps.
10740. Mathis, S..... Regulators for electric lamps.

ABSTRACTS OF BRITISH PATENT SPECIFICATIONS.

Compiled from the Published Specifications by W. E. Heys, 70, *Market-street, Manchester.*

ENGINEERING.

Iron and Steel.—*J. Toussaint, Brigg, Lincolnshire.*—The inventor proposes the addition of fatty matters, either alone or mixed with some alkaline salt, to the molten iron or steel. The object of this addition is to destroy the oxides present in the metal, and to liberate the pyrites, and to cause them to rise to the surface. One claim is made.—No. 8968. June 23rd, 1887. 6*d*.

Water Motors.—*W. Tee, London.*—These improvements relate more particularly to those hydraulic engines which are employed for working organ bellows. The auxiliary valve for distributing the water to the main valve is dispensed with, and a single valve is provided to control the distribution of water to itself, as well as to the working cylinder. This valve is in the form of a hollow piston, which works in a cylinder connected with the motor cylinder, and is provided with ports on its circumference which work over ports leading to the motor cylinder. The valve receives a reciprocating motion by the pressure of water acting alternately on its opposite ends, and also a reciprocating rotary motion for the purpose of controlling the distribution of water to itself; for generating the latter motion, a tappet is worked by the main piston rod, and acts on the valve spindle either directly or indirectly, according to the relative positions of the valve and the main cylinder. If the motions of the valve and main piston be parallel, the tappets may be made to act on the valve spindle through the agency of an inclined cam or other contrivance for changing the direction of the motion at right angles. Springs are interposed for the purpose of rendering the opening of the valve gradual. Another improvement introduced by this invention relates to the regulating valve for cutting off the supply when the bellows are full of air. Hitherto the valve has been of the screwdown pattern, but by this invention the valve operating lever is geared with the valve spindle by means of a rack and pinion; the valve may thus be kept closed more effectually with a shorter lever. The valve spindle is provided with rack teeth, and the lever is fixed on a shaft at right angles to the spindle, and is geared to the spindle by a pinion. Four claims are made: (1 and 2) For the valve for hydraulic engines, consisting of a hollow piston, receiving both longitudinal and circular reciprocating motion in a cylinder, the valve and cylinder being provided with ports, and being used to control the distribution of water to the motor cylinder and to itself; (3) for the combination of the valve, tappet, and cam gear, with the springs for partially rotating the valve; and (4) for the rack and pinion gear for regulating the supply.—No. 15657. November 15th, 1887. 8*d*.

Rotary Pumps and Blowers.—*O. Imray, London.* (*J. Dow, Philadelphia.*)—Fig. 1 is a longitudinal section of the duplex rotary pump, and Fig. 2 is a transverse section of the piston and abutment valve. The shell A is divided into two parallel chambers B C by a vertical partition D, which is continued

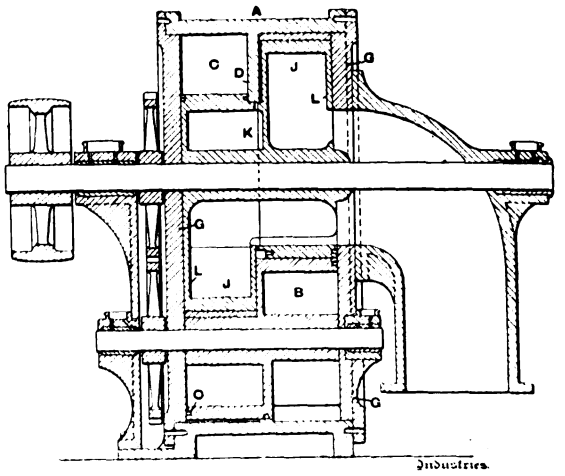

Fig. 1.

through the pipe E to the seat of the valves N. The partition D has an upper circular opening which receives the duplex cylinder, and a lower segmental opening separated from the other opening by a ridge. The piston cylinder K is made in two parts, each carrying a piston J; the ends of the two parts are shouldered down, and the reduced parts enter the upper circular opening, in the middle of which they meet. At each end of the pistons is a thin wing L. The revolving abutments are constructed in one piece in the form of a cylinder, which has two diametrically opposite recesses F, constituting piston openings

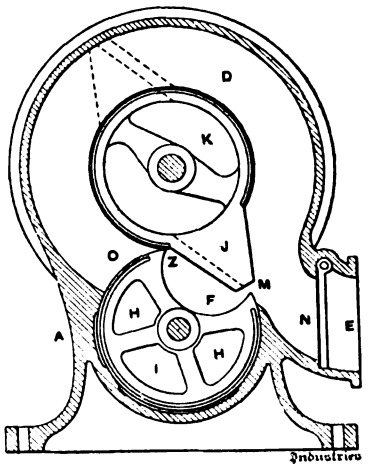

Fig. 2.

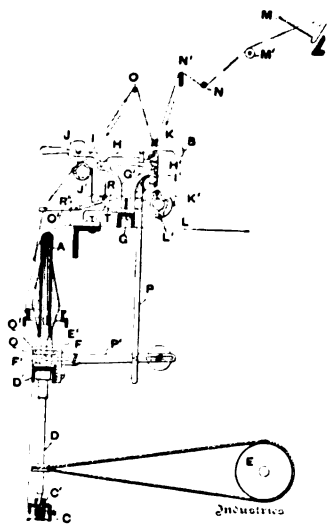
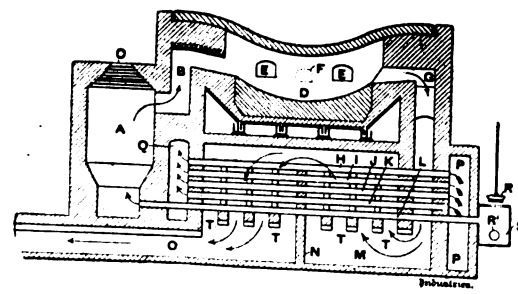


one on each side of the partition D. The ends of the abutments fit closely against the sides G. Two openings H pass from end to end of the abutment cylinder, and other openings I stop at the partition in the middle of the cylinder, which forms the inner wall of the piston openings F. When the piston is entering one of the openings F, as seen in Fig. 2, there is a clearance M for the outflow of the fluid, which would otherwise be imprisoned in F. A valve N is placed in the discharge pipe E so as to prevent any back flow when the piston J is in the position shown in Fig. 2. Three claims are made for making the abutment cylinder in one piece, with opposite openings for the passage of the pistons, with interior chambers open at the ends, and with grooves for fluid packing.—No. 2252. February 14th, 1888. 8*d*.

Steam Pressure Reducing Valve.—*G. Spencer, Hyde, Cheshire.*—A rotary valve works within a tubular chamber and corresponding ports in the valve, and the walls of the chamber are so arranged that the partial rotation of the valve shall regulate the admission of steam. The position of the valve is controlled by a piston, which works in a short vertical cylinder on the low pressure side of the apparatus. A piston rod attached to the piston is weighted by a lever and weight, or by a compressed spring, preferably the latter. When the steam at the desired reduced pressure is acting upon the under side of the piston, the valve will be held in an intermediate position between open and closed. If the pressure increases on the reduced side, the piston will be lifted to a greater or less extent, and the valve will be correspondingly closed; and if the pressure diminishes the valve will be more widely opened. Two claims are made for the combination of the valve, rods, piston rod, piston, cylinder, and spring, for the purpose described.—No. 8331. June 10th, 1887. 8*d*.

Digitized by Google

PLANING MACHINES.—*T. H. Martin, Swansea.*—This invention relates to a double acting rest and tool holder, which will enable a horizontal metal planing machine to cut both ways instead of only one way as heretofore. The cutting tool is fixed to the tool stock in the usual way, and is provided with two cutting edges, one on each of the opposite sides of its cutting face, so that it is only necessary to alter its inclination at the end of each stroke in order to prepare it for the return. This reversal of the tool is effected by the self acting feed to the cross slide at the over-run; the belt striking gear of the feed motion moves a cord running over a pulley, which in its turn moves a crank rod, whose backward and forward motion changes the inclination of the tool stock. The reversal of the tool can also be effected by a travelling wheel, which runs on a rod with a shunt, or by means of a cross spindle, pinion, and quadrant. The tool is bolted to a special tool stock which oscillates freely to and fro on the flapping tool box by means of slots in the form of arcs of circles, and pins projecting from the tool box work in the slots; or the tool stock may be pivoted in its centre to the tool box. The amount of oscillation is regulated so as to insure the proper position of the tool for cutting in either direction, and the tool is supported by stops on either side. The flapping tool box differs from the ordinary kind by being arranged to allow this oscillation of the tool stock and tool. Three claims are made for the use in planing machines of a tool with two cutting faces, or of two tools set back to back with cutting edges in opposite directions in combination with the reversing motion as described.—No. 6544. May 4th, 1887. 8*d.*

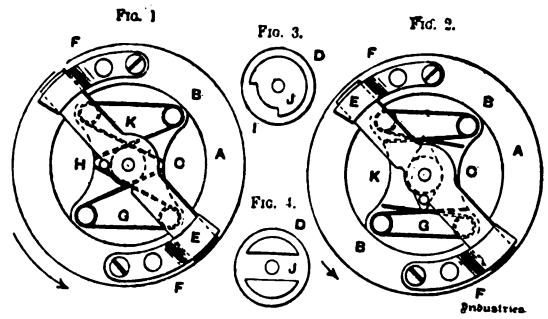


DOUBLING AND TWISTING YARNS.—*E. Sykes & D. Sykes, Huddersfield.*—This invention consists of a self acting mechanism for stopping the delivery of yarn when any of the threads break; the feed rollers and bobbin are caused to cease rotating, while the motion of the spindle, driving band, and tin cylinder is not interfered with. The figure shows a section of the improved machine when the threads are intact. The spindle D is driven from the tin cylinder E, and the bobbin A may be stopped while the spindle rotates by raising the cone F on the bobbin out of contact with the cone F¹ on the spindle. The bracket G¹ supports the rocking frames H H¹, which are pivoted at I and I¹ respectively; the drop wire frame H¹ is provided with notches, which

fit into corresponding notches in H. The roller K¹ is driven from the main shaft, and carries two projecting rods L¹. The two feed rollers are shown at J J¹. When the thread breaks, the eyelet K on the frame H¹ descends, and its lower end comes in contact with the rods L¹; the frame H¹ is thus oscillated, and its upper end with the notches in it moves to the right and allows the right hand end of H to descend. The feed rollers are thus separated, and the delivery of thread is arrested; at the same time the rod P moves downwards and causes the cone F to be raised, with the result that the bobbin ceases rotating. An additional apparatus is added in case the thread breaks between the feed rollers and the bobbin. The eyelet O¹ is placed at one end of a lever R, which is pivoted at R¹; the lever carries a rod at the other end, which passes through an eyelet in a sliding vertical rod in the frame H¹. When the thread breaks, the eyelet O¹ ascends and the other end of the lever descends, and the same train of mechanism is put in action as before. Three claims are made for the frames H H¹ and balanced lever R.—No. 8325. June 10th, 1887. 8*d.*

CARDING ENGINES.—*G. Eastwood, Rochdale.*—The object of this invention is to divide the material into slivers on the doffer before it enters between the rubber leathers. A shaft is mounted between the stripper and the doffer, and it carries a number of circular pieces corresponding to the number of spaces on the doffer. The surfaces of the circular pieces are covered with fillets of card, and are made to approach the surfaces of the doffer and stripper, and to enter the ring spaces which are formed in each. In proximity to the dividing roller is a shaft which is also provided with circular pieces and covered with fillets of card; the office which this shaft performs is to prevent the uniting of the threads at this part of the process, and to insure the separation of the threads before entering the rubber leathers. Another roller is mounted close to and at any convenient part of the under side of the doffer, and is provided with strips of metal which project beyond its surface in the longitudinal direction of the roller. When the engine is in operation a rotary motion is imparted to the latter roller, and by this means the loose fibres, when passing from the cylinder to the doffer, are straightened, and the material is thus caused to pass between the doffer and the roller in a regular form. The revolving shaft situated between the stripper and the doffer insures by means of the circular pieces an effectual division of the slivers; from thence the slivers pass to the dividing roller, and the other rotating shaft carrying the circular pieces obviates the possibility of the re-uniting of the threads on the dividing roller. Four claims are made for the combination of these rollers.—No. 16024. November 22nd, 1887. 8*d.*

OPEN HEARTH FURNACES.—*H. Burrows, Plumstead, Kent.*—According to this invention the gas producing chamber A communicates with the melting chamber D by way of the opening B. The products of combustion pass out through the opening G, and while in their hottest state pass between the series of regenerating tubes H I J K L; the hot gases afterwards



enter the chamber M, which is provided with a partition N for the purpose of thoroughly diffusing the gases among the tubes. The air is admitted through a valve into the chamber P, from whence it passes through the tubes and becomes heated. When it arrives in A it is mixed with gas which is supplied through the valve R and tube L. A tube R¹ is provided in case a forced draught is required. The inventor claims the regenerating air chambers arranged under the melting chamber so as to allow the heated air to pass through, in combination with the means for diffusing the heated gases among the regenerating tubes.—No. 8207. June 7th, 1887. 8*d.*

RAG ENGINES.—*G. Hibbert, Gateshead.*—This invention relates to improvements in protecting the roll bars and plates of rag engines from corrosion, so that their working edge shall last longer. Thin hard plates are placed on one side or on both sides of the roll bars and plates; these thin plates may be made of brass or phosphor bronze, or any other non-corrosive metal, and they may be either straight or corrugated. The side of the plate next to the steel bar is made slightly hollow, so that the plate will be tight in its place when keyed. Three claims are made.—No. 7779. May 28th, 1887. 6*d.*

STEAM PUMPS.—*G. G. Picking & W. Hopkins, London.*—The double cylinders, pistons, and steam ports are so arranged that the steam is distributed to the alternate ends of each cylinder by the movement of the piston without the employment of any slide valve. The cylinders are placed side by side, and a set of ports are made at about the middle of each cylinder leading to the two ends of the other cylinder. The pistons are hollow, and of a somewhat greater length than the stroke. The steam is conveyed to the respective ends of the cylinders by the movement of the piston passing the ports in the cylinder. Three claims are made.—No. 8355. June 10th, 1887. 8*d.*

ELECTRICITY.

ELECTRICAL SWITCH.—*S. Sharp, J. M. V. Money-Kent, and H. J. Payne, London.*—This invention relates to that class of switch in which the contact bar is operated partly by hand and partly by an independent auxiliary force. Fig. 1 represents the switch when "on," and Fig. 2 in an intermediate position, and Figs. 3 and 4 are inverted plans of two arrangements of the handle. The four pins B are cast upon a plate K, and the contact plates F are fixed to the base plate A. A block C is pivoted centrally upon the hollow spindle on the plate K, and

one or two pins H are carried on its upper surface. Two independent springs are secured round the pins B. The operating handle D is secured to a spindle which passes loosely through the contact bar E, and through the hollow spindle of the block C; its lower surface carries a plate J, which may be of either of the forms in Fig. 3 or 4, and is adapted to take against the pins H. When the switch is required to be turned "off," the handle is rotated in the direction of the arrow in Fig. 1; the side of the plate J then comes against the pin H, and the rotary block is turned, and the springs consequently compressed. After a quarter revolution the block arrives at the dead centre position, as in Fig. 2, and the springs are in full compression and ready for action. On the further rotation of the handle, the springs cause an immediate motion of the contact bar, and the contact is thus broken instantaneously. Three claims are made for this arrangement of rotary block and springs for breaking contact instantaneously.—No. 3685. March 9th, 1888. 8*d.*

LIGHTING RAILWAY CARRIAGES BY ELECTRICITY.—*J. L. Yuly and H. W. Andrews, Southsea, Hampshire.*—The object of this invention is to provide a means by which the speed of a dynamo worked by the rotation of the carriage axles can be altered to suit the speed at which the train is running, and to automatically switch the storage batteries on and off when the train is running too slowly or quickly. A wide drum is placed on the axle of one pair of wheels, and open and crossed belts passing around it drive three pulleys on a countershaft, the middle pulley being fixed, and the others loose. Expanding pulleys are keyed to the countershaft, and to the axle of the dynamo. These pulleys have their bosses, by means of which they are keyed to their shafts, formed into conical driving pulleys, which by means of belts drive similar cones on short shafts parallel to the other shafts. These short shafts have ordinary driving pulleys keyed to them, which by means of belts drive similar sized pulleys on the sleeves carrying the expanding cog wheels. The sleeves carrying the cog wheels run loose on the dynamo shaft and on the countershaft, and are kept in gear with their respective pinions by means of collars. By shifting the belts along the cones, the bevel cog wheels are made to run faster or slower than their respective expanding pulleys, and thus set the pinions in motion and increase the diameter of the expanding pulleys. The belt slipping devices are fitted with springs, so that when the hand lever is released the belts immediately move to the middle of the cones. Storage batteries supply the current to the lights while the train is stationary, or is travelling too slow to work the dynamo, and switches are connected to a suitable governor, which is attached to the dynamo or countershaft, so as to disconnect the batteries from and connect the dynamo with the lights when the speed of the dynamo reaches the requisite number of revolutions. The inventors make three claims for the application of expanding pulleys, cones, and belts, for the purpose described.—No. 9256. June 29th, 1887. 8*d.*

CUT-OUT AND SWITCH.—*A. Bernstein, London.*—This invention is an improvement on the instrument described in Patent No. 12315 of 1886, and the object is to provide suitable receptacles for the cut-out plugs, so that they can at the same time serve as switches. The two metal standards F G are supported on the insulating material E, and receive the screwed plug H. The metal end I is attached to the plug by the insulating strips I², and the stud I³ presses against the special compound placed in the recess in I¹. The standard G carries a flat spring J, which makes contact at one end K with the end I¹ of the plug, and at the

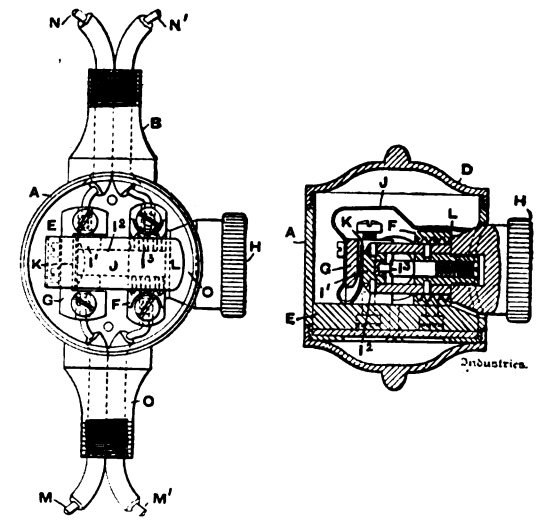


FIG. 1. FIG. 2.

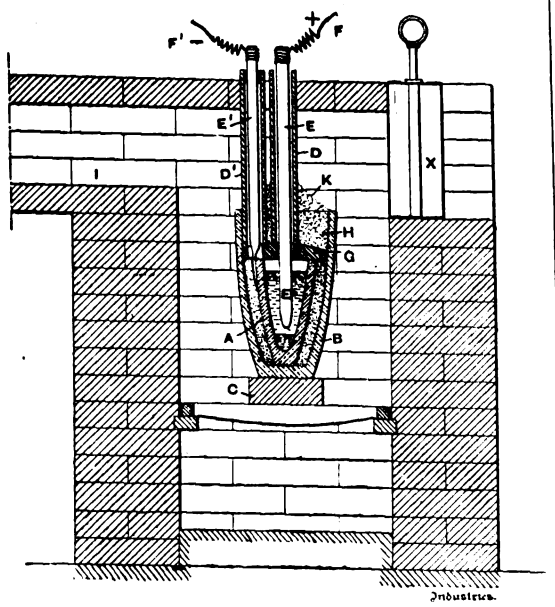
other end L with the standard F when the plug is not screwed up. M M¹ are the main conductors, and N N¹ are the conductors of the lamp circuit which are attached to the standards F G. As soon as the plug is put in place, as in Fig. 2, the metal end I¹ makes contact with the end K of the spring, the metal portion I being in contact with the standard F. The two standards are then only connected through the metallic compound, so that almost the total current passes to the lamp. If the plug is turned slightly out of the case, so that the end L of the spring comes into contact with the standard F, the current will be short circuited through the spring J, and no current can pass through the lamp. The plug will thus work either as a cut-out or as a switch. Two claims are made.—No. 3740. March 10th, 1888. 6*d.*



CHEMISTRY.

SULPHATE OF AMMONIA.—*H. C. Bull & Co., and W. E. Sendey, London.*—The inventors first convert purified clay into aluminium sulphate by the action of sulphuric acid, and then introduce gaseous ammonia into the solution, thus converting the salt into sulphate of ammonia and precipitating the alumina. The purification of the clay is effected by mixing it with an excess of water, and by passing it over a series of weirs, which are arranged in chambers; the repeated reversals of the direction of its flow cause the heavier foreign substances to be deposited. After this process is completed the suspended clay is allowed to settle in large tanks. The fine deposit is then delivered into a specially arranged series of leaden chambers where sulphuric acid is being produced. These chambers are round in shape, and are slightly inclined; each of them has a shaft through its centre carrying propeller blades, which convey the clay mixed with sulphuric acid from one end to the other. In passing through the chambers the greater portion of the aluminous material is converted into sulphate of alumina, which is held in solution by the water. The solution is again passed into settling tanks, from which the clarified solution is removed to another vessel, where it is brought into contact with gaseous ammonia. The result of the latter operation is to produce sulphate of ammonia and alumina. The by-product alumina is purified by dissolving it with muriatic acid in order to convert all foreign metallic substances contained in it into chlorides, and is then subjected to a great heat, preferably on a hearth of pure alumina. The chlorides all pass off in vapour, and leave the alumina substantially pure. When this process is carried out at

Digitized by Google

a gas works, a large portion of the sulphurous acid necessary to make the sulphuric acid may be conveniently obtained from the oxide of iron used in purifying the gas; and the ammonia can be readily obtained from the gas liquor. The chief novelty of the invention is the production of sulphate of alumina, and so avoiding the expense of concentrating the sulphuric acid, as is necessary in the ordinary processes. Three claims are made for the process, for the plant, and for the utilisation of the by-product alumina.—No. 9543. July 6th, 1887. 8*d*.

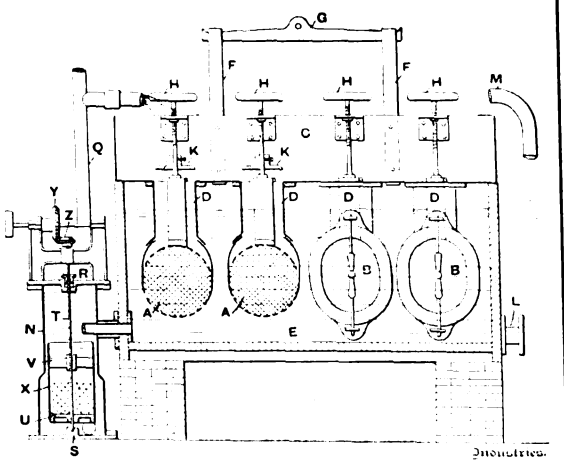
Extraction of Aluminium.—*A. C. Henderson, London.* (*P. S. T. Héroult, Paris.*)—According to this invention aluminium is extracted from its oxide by electrolysis, and cryolite is used as a flux in fusing the alumina. The crucible A is formed of very dense and well conducting agglomerated carbon, and acts as the negative electrode. It contains a bath of cryolite, and is placed within another crucible B, which is made of graphite. The pencil-shaped agglomerated carbon rod E¹ serves as a positive electrode, and dips into the bath of cryolite; the carbon rod E¹ is in direct contact with the crucible which forms the negative electrode. The crucible A is closed by a lid G of refractory material, which is covered with fire clay H, and a layer of loam K. When the cryolite, to which the alumina has

been previously added, has been reduced to a molten state by the heat of the furnace, an electric current is sent through it, and the alumina is electrolysed. The oxygen evolved from the alumina unites with the positive electrode E, which, being brought to a high temperature, combines with the oxygen and forms oxide of carbon, and the gas thus given off escapes through the tube D. The tube D¹ is kept closed to prevent the entrance of air. The aluminium passes to the internal walls of the crucible A, where it first settles, and it afterwards falls to the bottom of the crucible. The cryolite remains unchanged. In order to render the production of metal continuous, alumina is added from time to time as required to replace that which is decomposed. For the practical carrying out of this process a current of 3 volts is found to be sufficient, which is a much less tension than has been hitherto employed. The reason for this is that, in the present process, the carbon of the positive electrode E, while it burns, yields an amount of heat which it is not necessary should be supplied by the electric current. When an alloy of aluminum is to be produced, a suitable metal such as copper is employed as the negative electrode, and by the action of the current of electricity both it and the aluminium are fused at the same time. Seven claims are made.—No. 7426. May 21st, 1887. 8*d*.

Manufacture of Sodium.—*J. B. Thompson, London, and W. White, Cheshunt, Hertfordshire.*—For the reduction of sodium the inventors mix the dry carbonate with a fluid hydrocarbon which is decomposable by heat, such as glucose or coal tar. A convenient mixture for this purpose consists of four parts of dry sodium carbonate and three parts of tar; these ingredients are formed into a smooth paste, which is raised to a dull red heat in a crucible. The mixture is afterwards calcined in iron pots, which are preferably introduced into the flue of the furnace; the flue is specially enlarged to receive these pots, so that the waste heat from the furnace may be fully utilised. In reducing the sodium the inventors employ a fire clay tubular retort, into which the calx is introduced after the retort has been raised to a red heat. At the opposite end of the retort is the exit to the condensing chamber, which is placed below the heated parts of the furnace. The receiver for the sodium is placed in the condensing chamber, and contains a little paraffin oil, in order to produce a non-oxidising atmosphere. The chamber is furnished with a pipe for the escape of the carbonic oxide, which, as it issues, is lighted, in order to indicate the continuance of the process. This method of reducing sodium may be also employed for the reduction of potassium. Three claims are made.—No. 8426. June 11th, 1887. 6*d*.

Hydrochlorate of Quinine.—*P. M. Justice, London.* (*L. B. Weld, Falmouth, Massachusetts.*)—In manufacturing the hydrochlorate of quinine a quantity of sulphate of quinine is boiled in alcohol, together with some common salt. The boiling is continued for about ten minutes, and at the end of that time the salts will have been converted into hydrochlorate of quinine and sulphate of soda. The solution is then concentrated and cooled, and the sulphate of soda and any excess of common salt [illegible] precipitated; afterwards the alcohol is evaporated, and the hydrochlorate obtained in a crystalline state. Two claims are made.—No. 3949. March 14th, 1888. 4*d*.

Pyroxyline Compounds.—*F. Crane, Short Hills, New Jersey, U.S.A.*—The object of this invention is to produce thin solutions of pyroxyline for use as lacquers and varnishes without the employment of heat. The acetates of propyl and butyl are used as solvents for the pyroxyline, as they have the special advantages that they evaporate with sufficient rapidity at ordinary temperatures, and that they are not hygroscopic. The following is a suitable mixture to form a pyroxyline varnish: Butyl and propyl acetates 4 gallons, benzine 4 gallons, methyl alcohol 2 gallons, pyroxyline 2½lb. Eight claims are made for the constitution of the solvents made by the mixture of butyl and propyl acetates with benzine, alcohols, or other light hydrocarbons as desired.—No. 8253. June 8th, 1887. 6*d*.

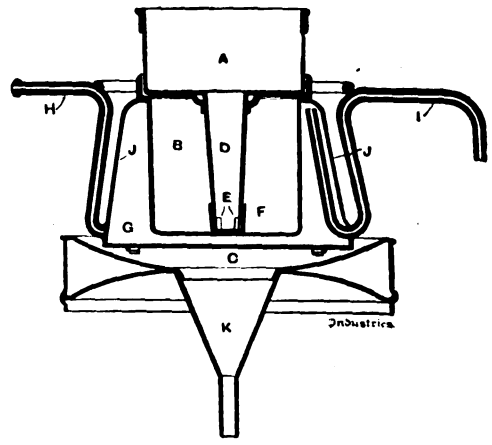


Platinum.—*S. P. Thompson, London.*—This invention relates to the electro-deposition in a bright metallic form of the metals of the platinum group. The chloride is dried and dissolved in distilled water, to which solution is added about thirty times its weight of a solution of phosphate of soda mixed with borate or carbonate of soda. After this mixture has been heated to its boiling point, a brightening substance such as sal ammoniac is added. Any acidity or alkalinity is removed by the addition of either bicarbonate of soda, or chlorine, or hydrochloric acid. This bath is then ready for the electric current. One claim is made.—No. 8284. June 9th, 1887. 6*d*.

Manufacture of Chlorine.—*W. Bramley, Middlesbrough.*—The inventor makes use of waste calcium chloride in order to produce chlorine and hydrochloric acid. The calcium chloride is intimately mixed with a suitable amount of calcined iron ore, and exposed to the heat of a furnace in the presence of a current of hot air. The result of this treatment is that a current of chlorine gas is evolved, which is sometimes mixed with gaseous hydrochloric acid, if there is any moisture present in the air. The residual material is utilised in the manufacture of iron, and consequently the lime contained in it effects a saving of expense in the latter process. One claim is made.—No. 8289. June 9th, 1887. 6*d*.

Aluminium.—*C. A. Burghardt & W. J. Twining, Manchester.*—The inventors take a certain quantity of aluminium sulphate, and precipitate the hydrated oxide by the addition of ammonia. After the oxide has been washed, there is added to it a quantity of caustic soda sufficient to convert it to the aluminate. To this solution potassium cyanide and bicarbonate is added, and after it has been boiled a stream of hydrocyanic acid gas is passed through it. An electric current is then applied, and the aluminium is deposited. Three claims are made.—No. 9389. July 2nd, 1887. 6*d*.

MISCELLANEOUS.

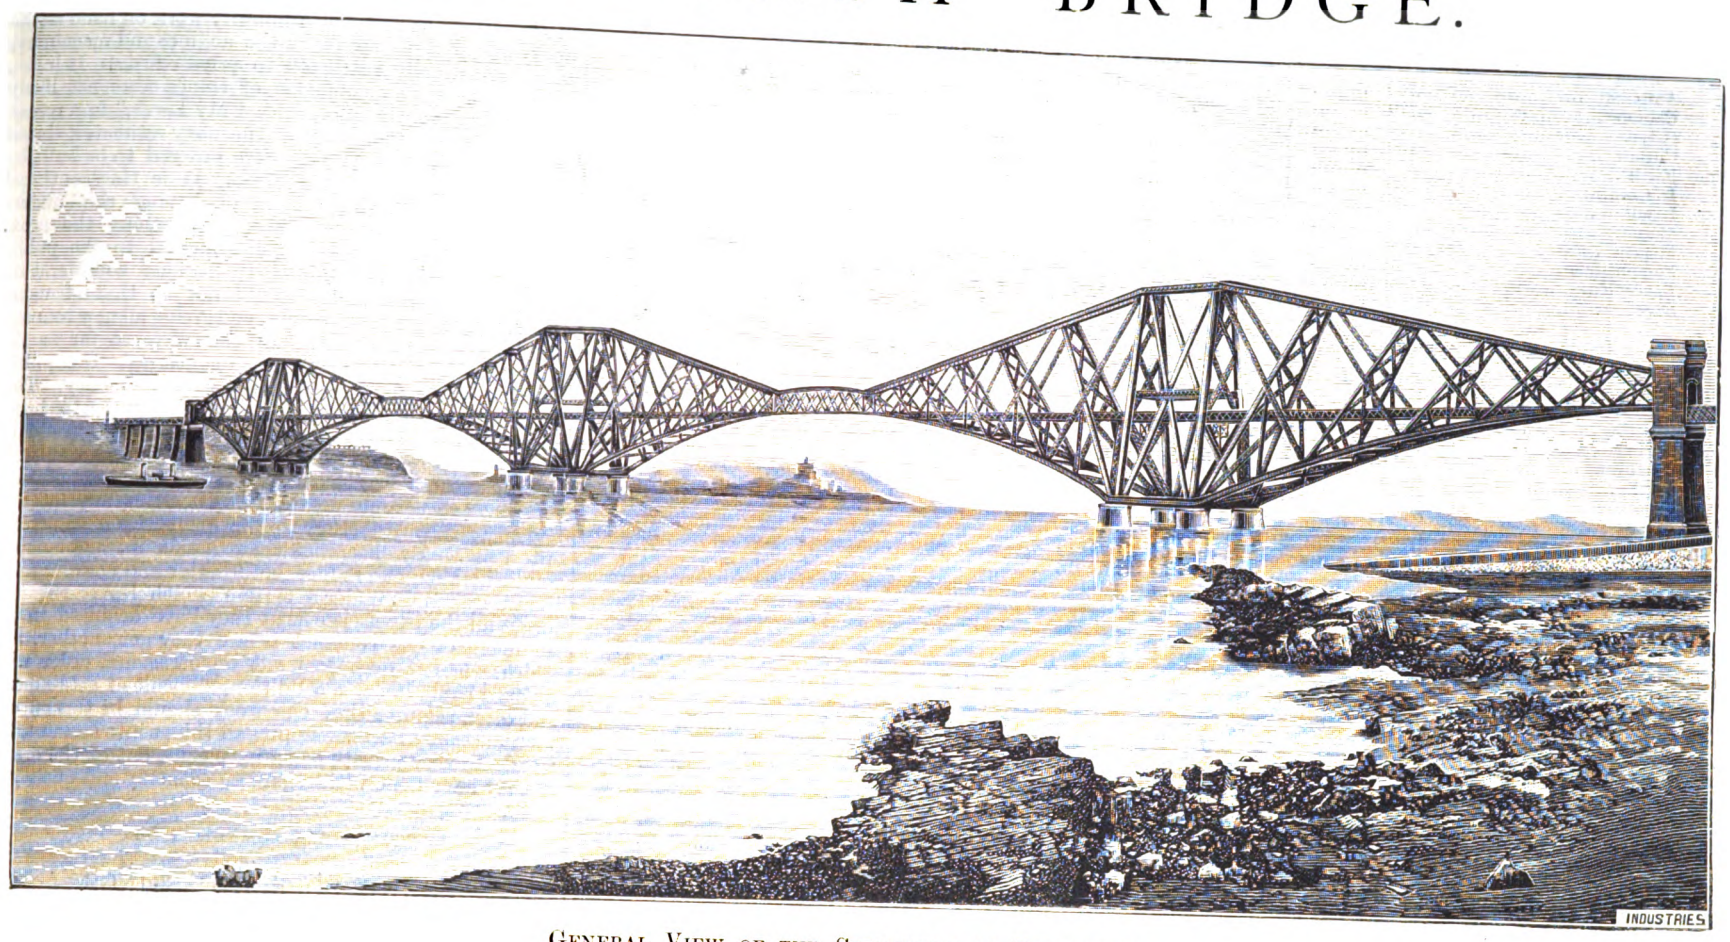


Dyeing Apparatus.—*A. Harmel, M. Harmel, & F. Harmel, Val des Bois, France.*—The apparatus consists mainly of a movable metallic framing, in which are placed horizontal receptacles to contain the material to be dyed. The lower parts of the receptacles are partly perforated, and the upper part constitutes a reservoir for the dye. The dyeing liquor is drawn from time to time from the bottom of the vat, and is passed back into the reservoir, from which it descends through the materials, and issues through the perforations of the receptacles. The accompanying figure illustrates one of the arrangements according to this invention. The metal structure carrying the bobbins of material consists of one or more horizontal receptacles A, which have one end hermetically closed, while at the other they are

provided with a removable cover B. The tubes D attach the receptacles to the bottom of the reservoir C, which rests upon the dye vat E. The bobbins may be compressed between the perforated bottom of A and a curved perforated plate I by means of the screws H, and the loops F and cross bar G assist in the removal of the entire structure from the vat. The apparatus for effecting the circulation of the dye liquor consists of a cylindrical casing N, connected by a tube O to the vat E, and having a branch pipe at the bottom connected to the ascending pipe Q for conveying the dye into the reservoir C. A vertical shaft T is fixed by a disc U and a cross bar V to a perforated cylinder X, and rapid rotary motion is imparted to it. The liquor is delivered from the vat E into the open end of the cylinder X, and the centrifugal action of the latter causes the liquid to be forced into the reservoir. Six claims are made for the construction of this apparatus and for modifications.—No. 3753. March 10th, 1888. 11*d*.

Terra Cotta Fire Proof Articles.—*M. H. Blanchard, Bishop's Waltham, Hampshire.*—Round iron rods or tubes are placed in the moulds, and the plastic clay is afterwards inserted all round them. After having been partially dried, the rods are withdrawn and the article burnt in a kiln. The slabs, which may be of any shape, are then utilised by being placed round iron columns or girders in order to form a protection for them from fire. Iron tubes are passed through the holes in the blocks, and they serve as the means of circulating cold water through the structures. Three claims are made.—No. 326. January 7th, 1888. 8*d*.

Heating Liquids.—*H. H. Leigh, London.* (*J. Bernström, Stockholm.*)—This invention relates to an apparatus which is intended for heating liquids before they are operated upon in a centrifugal separator. The liquid is filled into the receptacle A, from the lower end of which the tube D descends into a socket F in the bottom of the heater B. The lower end of the tube D and the socket are provided with slots which correspond with



one another, so that the supply of liquid to the heater can be regulated. The space G is filled with water or other liquid, which is heated by steam from the steam pipe H, and the excess of water in G arising from the condensation of the steam flows out through the pipe I. The liquid to be treated is first heated inside B, after filling which it flows over the top and along the inclined shell J in a thin layer. The heated liquid is collected within the bowl C, from whence it may pass through the funnel K to the separator. Two claims are made for the combination of the parts marked A B H I D E F.—No. 3976. March 14th, 1888. 6*d*.

Filter Presses.—*S. H. Johnson & C. C. Hutchinson, London.*—The improvements here introduced into the construction of filter presses are intended to facilitate the opening of them after they have been filled, and to enable them to be worked at high pressure. Usually the loose sliding head of an ordinary filter press has been moved to and fro to open or close the press by means of a central screw, and when the press was worked at a high pressure it was necessary to have a fine pitch on the screw; in consequence, it required many turns of the screw to open or close the press. The present inventors remedy this defect by providing the sliding head with a hollow tubular boss, which projects from the centre of the back of the head, and is open at its rear end. The internal diameter of the tubular boss is made large enough to allow it to slide freely over the screw. A thrust block is also provided, which can be interposed between the end of the screw and the boss, for the end of the screw to work against. This block may either be hinged to the boss, or it may in other ways be made readily removable from the part in front of the end of the screw. When the press is to be opened, the screw is turned back until the thrust block is relieved from pressure; the thrust block is then turned aside, so that the sliding head can be run quickly back; the screw afterwards passes into the interior of the hollow boss. In order to enable one workman at one side of the machine to run the sliding head back easily and rapidly, the inventors mount it on two small wheels running on the side bars of the machine. These wheels are fixed on a common axle, which moves in journals, and is provided at the end with a crank handle or hand wheel, by means of which both wheels can be simultaneously revolved, and the machine thus opened or closed. For the purpose of turning the central screw when required, the inventors make use of a spur wheel, which gears into a pinion attached to a capstan revolving and sliding on a fixed mandrel on the screw standard. Another method of effecting the same object is to fix the spur wheel on the central screw by means of a feather, along which the spur wheel can slide in an axial direction, at the same time revolving with the screw. In order to increase the strength of the screw threads, and to diminish their pitch, a form of thread is employed which has a flat surface at right angles to the axis. This surface sustains the thrust when the press is screwed up; the side opposite to that on which the thrust comes is inclined at such an angle to the axis of the shaft as to make the surface of attachment of the thread to the shaft the greatest which the pitch will admit. The inventors make seven claims—for the sliding head with the hollow, for the boss, for the removable thrust block, for the construction of the screw, and for the method of working it.—No. 9521. July 5th, 1887. 8*d*.

The full specifications of the British and United States patents, and the Official Journals of the German Patent Office, from which the above abstracts have been compiled, and the Official Journal of the United States Patent Office, may be seen by subscribers and clients at the Reading Room, Manchester Office of Industries, *where also Patent Indexes from* A.D. 1617 *may be consulted. Copies of the British specifications may be obtained on application to* H. Reader Lack, Esq., *Comptroller-General, Patent Office, Southampton Buildings, London, W.C. The published price must be remitted, together with a sum sufficient to cover postage, which may be reckoned at* ½*d. for every* 10*d. or fraction of* 10*d. Remittances exceeding one shilling must be made by Post Office Order.*

THE FORTH BRIDGE.

General View of the Structure as Completed.

Diagram Showing the Work Erected up to the End of June, 1887.

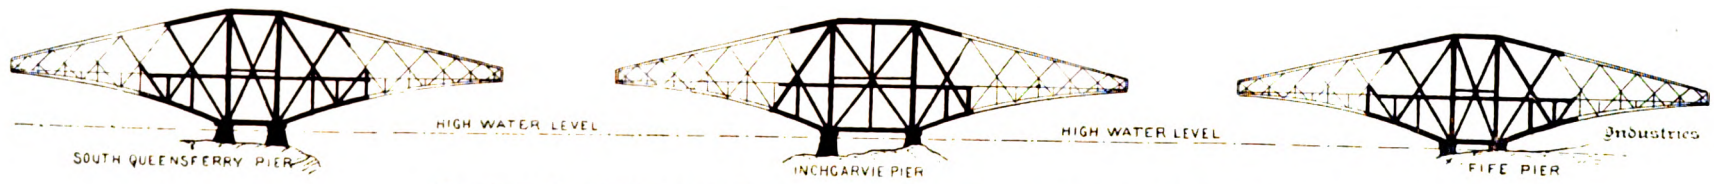

Diagram Showing the Work Erected up to the End of May, 1888.

THE FORTH BRIDGE.

Our illustrations give a perspective view showing the bridge in its completed state, and two diagrams which illustrate the condition of the structure in June last and at the end of last month. By comparing the two diagrams, the progress made since the middle of last year will be easily seen, as the thick black lines represent those parts of the structure which were then and are now erected. It will be seen that considerable progress has been made in the construction of the cantilevers, as at this time last year the main columns only with their bracing had been put in place, and the bottom member of the cantilever had only just been begun. In an early issue we propose to give some further illustrations, and a more detailed description of the work of the bridge.

DOCKYARD v. PRIVATE CONTRACT WORK.

II.

In our last article we referred to the great cost of superintendence in our dockyards, but they are equally at fault in regard to the purchase of materials. The British Admiralty have, without a single exception, established dockyards in localities unsuited for the purchase of materials on reasonable terms. Had one dockyard been constructed on the Clyde and another on the Tyne, the materials of construction could have been purchased minus the heavy item of cost of transport with which they are now weighted, while the Government would have had the very considerable advantage of a much larger command of skilled shipbuilding labour. As it is, they have to pay from 10s. to 20s. per ton more for their iron, steel, and other materials than they would have to pay if the dockyards had been set down in more suitable localities. We do not forget that a hundred years ago, when most of the existing yards had already been established, the iron industry of this country was largely carried on in different districts than the present, and also in those days timber and not iron was the material chiefly employed. Since wood has been superseded by iron the whole of the conditions of naval combination have been radically changed, and if considerations of economy were uppermost with "My Lords of the Admiralty," it would be well worth their while to consider the propriety of setting up a dockyard, say near the great northern coal field, and within a few miles of those great works whence they buy their materials. This, however, by the way. The immediate question before us is whether the Admiralty are able, or if able, whether they make it their care, to buy materials as cheaply as a private shipbuilder would do in their geographical position. We do not hesitate to say that the facts are all and altogether against them. Their own records show that they do not buy in the cheapest markets, although they do produce in the dearest. It is not always easy to bring this to the test of actual figures, but there is a great deal of collateral evidence on behalf of the statement we have just made. One most remarkable fact is that the average cost per ton of the work now turned out of Her Majesty's dockyards is about £110, or just about double what it was fifteen years ago, concurrently with a reduction in prices all round, amounting probably—as regards iron, copper, lead, and other constructive materials—to not less than 40 or 50 per cent. This difference is, no doubt, to some extent enforced by the greater complexity and refinement of mechanism adopted in modern ships of war; but as against that consideration the greater cheapness of materials ought to have counted for much more than it has done.

The Admiralty is accustomed to publish two statements of the cost of the work done by private shipbuilders and in dockyards which are mutually contradictory, and which demand explanations that never appear to have been made. In one statement they show the tonnage built by private contract from year to year, along with what purports to be a record of its cost. In another they show the actual expenditure incurred in turning out completed vessels by both systems. If we take the average cost per ton of unarmoured vessels turned out by private contract under the former series of accounts, it appears that between 1870 and 1885 some 44,513 tons of hull thus produced cost an average of £114 per ton, as against an average of £78 per ton for 79,364 tons of unarmoured vessels turned out of the dockyards in the same period. But when we get to closer quarters, and

look into the total cost of the ships built by private contract, the average cost does not usually exceed, and often falls below, £50 per ton of displacement. Now, this system of having two different standards of measurement—the one by weight of hull, and the other by displacement, is exceedingly liable to confuse and mystify. But, putting that on one side, we find that the detailed and complete returns of the total cost of hulls and engines do not bear out the idea of private contract work being more expensive; but, on the contrary, prove just the reverse. We have tested this in three separate ways: First, by comparing the cost of a number of unarmoured vessels, built in Her Majesty's dockyards and in private shipbuilders' yards respectively, previous to 1880; next, by comparing the same class of vessels similarly constructed between 1880 and 1886; and next, by comparing the cost of armoured ships built by each of the two systems also during the latter period. In every case the comparison comes out in favour of private builders' work—not to any very considerable extent, it is true, but still sufficiently so to justify a greater partiality for such work than the Admiralty has hitherto shown. Thus we find that the total cost of 20,780 tons displacement of unarmoured ships, built by private contract between 1875 and 1880, was £951,600, including engines, or an average of £45. 16s. per ton, as compared with £51 per ton for 22,930 tons of unarmoured vessels constructed in dockyards. In this case, therefore, the difference in favour of private contract work was £5. 10s. per ton. Between 1880 and 1886, which brings us as close as we can well get to the existing condition of things, the difference in favour of the private contract work on unarmoured vessels was reduced by 10s. per ton, that is to say, the dockyard work was still some £5 per ton dearer. The uniformity of this difference is peculiar and striking, and as the data with regard to the most recent vessels constructed may be instructive and useful, we give above some tables of comparative results on which the comparison for the period 1880-86 is founded, premising that the vessels in both cases are built of steel, and that they have been selected at haphazard from the list published in Lord Brassey's "Annual." The first table shows the details of a number of unarmoured ships built for the British navy at Her Majesty's dockyards from 1880 to 1886. The next table gives the number of vessels constructed in private yards of much the same description and classes, but we have been compelled to make a more limited choice, simply because the materials for the purpose in hand were less abundant, the work done by private contract being inferior in amount to that done in the dockyards. In carrying this comparison one step farther, and comparing with each other the costs of armoured vessels built by private contract and at Her Majesty's dockyards, it is desirable to remember that the latter have great facilities in being constantly employed with this class of work, whereas the construction of an armour-clad ship comes to a private firm very occasionally indeed. All the resources and equipment necessary for the work are therefore much more fully at the disposal of the dockyards, and yet their tonnage cost, as before, is higher than that of the private yards. In the case of private firms, we are compelled, as hitherto, to rest content with a more limited choice; but the smaller tonnage does not in any way vitiate the comparison or affect the general result, which is considerably in favour of private contract work.

How now is it possible to reconcile with facts like these the remarkable result presented in the annual statement issued by the Admiralty, purporting to show the total tons weight of hull constructed for the British navy in the dockyards and by private contract respectively? These returns, which anyone can easily verify for himself, show that between 1870 and 1885 there were constructed, of unarmoured ships:—

	Tons weight of hull.	Total cost.	Average per ton.
In the royal dockyards	79,364	£6,195,700	£78
In private yards	44,513	5,094,900	114

Being a difference of £36, or 46 per cent. against private shipbuilders. Truly, in this, as in other matters, the ways of the Admiralty are past finding out. On the second part of our subject, viz., the question of whether private shipbuilders receive a fair share of Admiralty work, we think we can afford to be very brief, because, having shown that private contract work is the cheaper of the two, and there being no allegation on the part of the authorities reflecting on its quality, it surely follows that in the interest of the public purse, the more of our new ships of war are put into the hands of private builders the better. Happily, the Admiralty has lately been mending its ways in this respect, and for the first time in the history of the navy, private shipbuilders had in 1886-87 about as much Admiralty work on hand as the dockyards, not to speak of the engines and machinery, which are usually entrusted to private firms. It looks, however, as if this condition of things were not likely to be of long continuance, since "My Lords," in a recent memorandum explanatory of the navy estimates, stated that only two new vessels were ordered to be built by private contract during 1887-88. It is this continual change of policy, this system of having shipbuilders well employed one year and doing nothing the next, that has all along been so detrimental to the public interest; and it is well worth serious consideration whether the true policy would not be that of using the dockyards for repairs only, and giving all new tonnage out to private contract. In this way—so far as the new vessels, at all events, were concerned—the public would be assured of having value for its money. This latter suggestion, of course, would be likely to bring about our ears the cry that the public interest would be endangered by leaving the building of our navy entirely in the hands of private shipbuilders. The only possible reply is that it would be the first time that any interest had suffered by resorting to the competition of private enterprise. By keeping their hands in, shipbuilders would be able to produce both better and cheaper work than they can do under a system which leaves them to forget all the experience that they have acquired in the fulfilment of one contract before they get another, and which, when it does deal out an occasional order with niggard hand, imposes conditions difficult of attainment, and often requires that the work should be turned out with unseemly haste. Taking all things into account, the wonder is that private firms have come out of the ordeal as they have done with regard to economy and quality of work.

SOUND COPPER CASTINGS.

It may seem somewhat strange to refer to "sound copper castings" when castings of all kinds are daily made with alloys whose principal constituent is copper. It is, however, a fact well known to brass founders that it is or has been hitherto impossible to obtain castings of copper in sand similar to those so readily obtained of iron and brass, all attempts to obtain such castings by the addition of small quantities of lead, zinc, tin, or other metal having been futile. The copper smelters and refiners, when casting cakes, ingots, and billets into moulds of iron and copper, and then quickly cooling the cast mass, are not always successful in obtaining castings free from little pin holes. The body of the casting is apparently perfectly sound, and until it is rolled into sheets or drawn into tubes the pin holes do not show their presence. These blow holes or pin holes show themselves when the cake or billet has been rolled or drawn by a line which opens out on the sheet or tube after being bent or tested, thus rendering the labour useless that has been spent on it. Owing to the same cause, a large number of copper rolls for calico printing have been rejected after a good deal of work has been expended upon them.

To obviate this source of loss a process has been recently brought out by Mr. R. Murray, Tylefield-street, Glasgow, whereby it is claimed castings in copper can be obtained with equal facility to those in brass or other copper alloys. The great deterioration in strength and ductility of the copper alloys generally used when exposed to relatively high temperatures was well shown by the experiments carried out in Portsmouth dockyard in the earlier part of last year (see *Industries*, Vol. III., page 2). The results of this investigation show the unreliability of brass or gun metal when exposed to temperatures of 300°F. and upwards, such as are now employed in triple and quadruple expansion marine engines. Copper alone, or when combined with zinc in the proportions used in the alloy known as Muntz' metal, retains its strength and ductility practically unimpaired to 450°F., a temperature far above that of any steam as ordinarily used. The conclusions of this report were emphasised by the bursting of a copper steam pipe on board the s.s. "Elbe" shortly afterwards, whereby ten men lost their lives, owing to the over-heating of the copper pipe while being brazed.

The castings made by the new process are said to be remarkable for their sharpness of detail, and for the beautiful skin and finish which they have when taken direct from the sand. They can, it is claimed, be cast with the greatest ease either in loam, dry or green sand, and in any thickness from an $\frac{1}{8}$in. upwards. The fluidity of the metal may be judged from the fact that a sheet about 6in. square and $\frac{1}{24}$in. thick was cast in green sand, and with such a fine surface that it seemed to have been rolled.

Digitized by Google

Ornamental placques are cast by this process, also name plates with letters in relief, from $\frac{1}{16}$in. thick, with all details clear and sharp just as they come from the sand; T and Y pieces of various sizes, bends, ornamental funnel tops, and rivets are also made by the same process; and the inventor guarantees them to be commercially pure copper. The analysis of two samples showed 99¼ per cent. of pure copper. The tensile strength is, on an average, 10 tons per square inch. This process offers the further advantage that when a number of bends or special pieces require to be cast, as in brass or made up from the sheet and brazed, the castings can be made much cheaper, and but slightly heavier than the built-up pipes, with a greater saving in weight than where brass is used; as the copper casting will stand a large amount of hammering at ordinary steam and even higher temperatures, when brass castings or brazed joints would lose their strength and become quite brittle. We understand that these castings have been tested under various steam and water pressures. At the present Glasgow Exhibition (Stand 85, Court 3) a number of these castings are to be seen, some polished and the others with the cast skin left untouched. The letters forming the name of "The Tharsis Sulphur and Copper Company, Limited," are shown. The bases and capitals of the columns at the corners of the glass cases are polished and turned, while the balustrades carrying the hand rail round the stand, as well as a casting of a tea cup, saucer, and spoon in one piece, with castings taken direct from the sand, and having the gates and runners still attached, give a very good idea of the capabilities of this new process.

HYDRAULIC COAL GETTING MACHINE.

In our issue of the 8th inst. we illustrated a hydraulic coal getting machine, invented by Messrs. Roberts-Horsfield & Porter, and we now give, as promised, some further particulars and illustrated details. Fig. 1 shows the machine in part sectional elevation, Fig. 2 is a cross section, Fig. 3 a plan, and Fig. 4 an end elevation. As will be seen from Fig. 2, the apparatus consists of a round steel bar A provided with a hole B running longitudinally through it and closed at each end. From this hole B a short slanting branch leads to the pipe B, which is connected to A in the manner shown. From B short passages C lead into cylindrical recesses in A, into which the rams D fit. The packing of the rams consists of a leather washer E, secured to the ram by means of a metal disc of a slightly smaller diameter than the ram, and a screw. On the top of the rams D is placed a crescent-shaped plate F (Figs. 1 and 2), which is secured to the first and last ram only by means of screws. The first and last ram are also provided with a groove, shown in Figs. 1 and 3, into which a projection of the plate G fits. The groove extends nearly to the cup leather E, and by this arrangement the rams are prevented from falling out or being forced out by the water pressure. When the rams are in their highest position, as shown in Figs. 1 and 2, the small perforations H (Figs. 2 and 3) are opened, and the water escapes without exerting any considerable pressure on the rams. As will be seen from the illustrations, the apparatus is nearly round when the rams are in their lowest position, so that it may easily be inserted into the hole made in the coal. As already described, the water is supplied through a flexible copper tube by means of a force pump, passes into B and through C under the rams D, which are gradually forced up. As soon as the coal gives way the rams reach their highest position, and the water escapes through the holes H.

IMPROVED FLOATING GRAIN ELEVATOR.

The problem of how to effect a rapid transference of goods to and from ships has been very successfully solved during the past few years, especially in the case of grain, for by the aid of elevators and conveyors it is now removed with great rapidity and economy. Fixed elevators, however, necessitate the berthing of a ship alongside the warehouse to which they are attached, and it has therefore during the past few years become the practice to use a portable elevator, by means of which a cargo can be unloaded and placed in any shed alongside of which a ship may be moored. The first type of portable elevator was one which could be lifted from a barge and dropped into the hatch, motive power being derived from an engine placed upon the deck of the ship, and obtaining steam by means of a flexible tube from a boiler carried by the barge. The use of elevators of this description has enormously increased, as is evidenced by the fact that in 1881 81,951 tons of grain were unloaded by their use, while in 1887 745,090 tons were so discharged in the two ports of Glasgow and Liverpool. These elevators are arranged to have two legs, so that they are practically

HYDRAULIC COAL GETTING MACHINE.

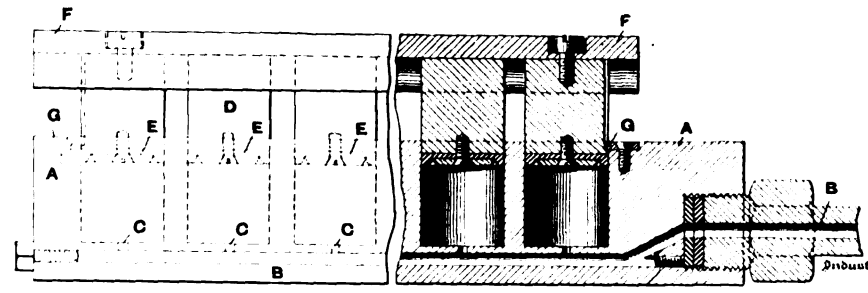

Fig. 1.

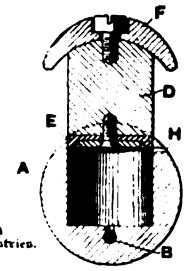

Fig. 2.

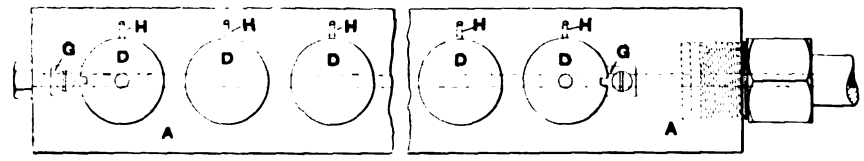

Fig. 3.

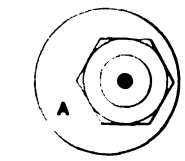

Fig. 4.

duplex, and lift the grain from each side of the ship simultaneously, thus keeping it in even trim. By stopping the operation of one leg, a ship which has a list can be brought upright. It is not, however, with the portable type that we have so much to deal as with a development of that idea which is embodied in a floating elevator. A machine of this class is illustrated in Figs. 1, 2, and 3, Fig. 1 being a side elevation, and Fig. 2 a plan of a single elevator, while Fig. 3 is a perspective view of the application of a duplex elevator to the purposes of unloading grain barges and delivering the material into sea-going vessels. Referring specially now to Figs. 1 and 2, it will be seen that the elevator is carried by a barge or pontoon moored alongside the vessel to be unloaded, and which also contains a steam boiler to supply the necessary power. The upright column is a double one—internal and external—the inner one being fixed to the lower base plate or foundation, and the outer to the upper plate. Between the two plates a set of rollers are placed, so that by means of a hand winch the case and bridge can be revolved, as is sometimes necessary in order to suit the position of a vessel, and to house the elevator. At the upper end of the pillar, two H section girders are attached, which form a bridge or jib for carrying the elevator trunk. In addition to having freedom of circular movement, the bridge can be raised or lowered at the point or nose as desired by means of the wire stays attached to the short end of each girder. This provision is made in order to allow of the elevator trunk being easily placed to suit the delivery, and also to facilitate the housing of the elevator, as will hereafter be described. The requisite power is obtained by means of the winding barrel shown. The elevator trunk is carried in a light wrought iron frame, through which it can slide, the frame being in turn sustained by trunnions, which enable it to be oscillated when necessary. In addition to the oscillatory movement there is also provision for moving the frame and trunk longitudinally on the bridge, by means of a traverse screw worked by a hand chain from the deck of the pontoon or barge. The range of longitudinal movement is of course limited, and is only intended to compensate for the variations existing in the beams of ships. To the head of the elevator leg or trunk is attached a wire rope, which passes over guide pulleys to a barrel, driven by gearing from a pair of engines fixed to the upper plate. By means of this the trunk can be drawn into a horizontal from the vertical position it is in when raising grain. A further lifting rope is taken from a third winding barrel, also driven by clutch gearing, and attached to a ring bolt at the lower end of the elevator case. In this way the latter can be vertically raised or lowered out of or into the hold of a ship, and can thus easily follow the height of the cargo as the latter is unloaded. Two pairs of steam engines are fixed on the revolving base plate, by which the whole of the motions are controlled, one pair driving the three winches described, and the other the elevator and conveyors.

The elevator trunk or leg is fitted internally with two endless chains, running parallel to each other over pulleys at the top and bottom, and to which are attached at short intervals steel buckets. The necessary motion is communicated to these chains by means of pitch chains of special construction, working on sprocket wheels, the chain from the engine driving a second one placed on a shaft running alongside one of the bridge girders, and so communicating motion to sprocket wheels, which drive the elevator and conveyors. This method is clearly shown in the illustrations. Attached to the elevator head is a telescopic delivery pipe, by which the grain is delivered to the conveyor band. If it is necessary to have more than one length of conveyor, a sprocket wheel is placed on the spindle of the roller at the extreme end of the first length, driving a similar wheel on the first roller of the second length. The distance to which the conveyors may be extended is thus very great, the whole of the power being derived from the engines on the pontoon or barge. The sprocket wheel and chain arrangement are of special design, easily detachable, and very convenient.

We had recently an opportunity to inspect a machine of this class which is being supplied to the Limerick Corporation, and we can testify to its easy and efficient working. We have referred to the housing of the elevator. This is requisite when it is out of use or when the machine is being moved from place to place, and is effected in the following manner: A cargo having been discharged, the leg or trunk is, by means of the lifting winch, drawn up clear of the ship's hatch. It is then drawn round until it lies on the bridge, which is swung round until it is fore and aft of the barge, being then allowed to fall at the nose, until the latter rests on a trestle placed on the deck of the barge, the whole being then made fast. The gearing, &c., is then closed up, and the barge is then ready for transportation without any fear of accident. The buckets are stamped out of steel, copper, or brass sheets in one piece; and even in the largest sizes are without a joint. A special plant has been laid down by the makers for this purpose, and they now make a large number of various sized and shaped buckets. The arrangement of these on the elevator chains is such that the maximum duty is obtained, as no space is lost in any way. Each machine is arranged to raise 50 tons per hour, but can, if necessary, raise 60 tons. The whole arrangement is most complete, and the machine we inspected worked well, and was well constructed.

Fig. 3 represents a machine constructed for the transference of grain cargoes from large barges to ocean-going ships—weighing it in the process. This machine was made for use at Odessa, the grain arriving at that port by large sailing barges. As will be seen, one elevator leg is sustained at the end of the jibs or derricks, and raises the grain from the barge, and delivers it to a conveyor. The latter empties it into a weighing machine placed on the pontoon carrying the elevator, which automatically weighs it, and delivers the grain so that it can be raised to the second elevator, which is carried by the upright frames shown. The second elevator delivers the grain to a conveyor, by which it is dropped into the ship. It will be noticed that the whole machine is mounted on a bogie or trolly running upon rails on the deck of the pontoon, so that the elevator legs can be dropped down either hatch of the ship. It should be stated here that, in using these machines, a special conveyor is necessary to bring the grain along the hold of the ship to the foot of the elevator, so as to avoid a good deal of hand labour. This special type of elevator is of course designed for the peculiar circumstances of the traffic; but the makers have to arrange each elevator for its special duty, although the general type is that shown in Figs. 1 and 2. These machines are finding ready acceptance, and are becoming more widely used yearly. The workmanship is exceedingly good, and the design is sufficiently strong without being unduly heavy, which is a point of some importance. The makers of both the portable and floating types are Messrs. S. S. Stott & Co., of Haslingden, near Manchester.

FOREIGN INDUSTRIES.

(From our own Correspondents.)

PARIS, 19TH JUNE, 1888.

THE IRON MARKET.—The situation of the iron trade has undergone no alteration within the last two or three weeks. The persistence of the same features, however, amounts to a change, as some little time ago the tendency of business was to expand, and hopes were entertained that a period of activity was approaching. The course of events, disturbed by political influences, has proved unfavourable to the development of the commerce of the country, both internal and external; and the iron industry has suffered in common with all the rest. Now the year is too far advanced to leave room for great expectations, and taking this fact into account with the low vitality of the iron trade in England, and the weaker aspect of the Belgian and German markets, hope of further improvement must be abandoned. Still, if the present state of things is maintained, there will be small cause for complaint. The Paris market is inactive, and disturbed by underselling on the part of the merchants; but taking the trade as a whole, there is a fairly strong current of business, and for the principal classes of goods prices are not unremunerative. The near prospect, too, is encouraging in the matter of profits, for manufacturers are strongly combined to resist the influences which tend to bring down prices. The pig iron trade of the Meurthe-et-Moselle is a little less animated, the buying on Belgian account, which gave a stimulus to the business of that district, having practically ceased. But there are no stocks on hand, and there can be no accumulation for at least some months to come, blast furnace owners having sold their output in most cases to the end of the third quarter of the year.

AGRICULTURE IN PRIMARY SCHOOLS.—Theoretical and practical lessons in agriculture are now being given every week in the primary schools of France. These lessons, which are given to boys and girls alike, include the care of cattle, dairy work, and everything which relates directly to farming. In order effectually to combine theory with practice, the pupils are taken once a week during the greater part of the year to the "demonstration plot," a piece of land set apart for the purpose of applying the principles taught in the school, and for affording an opportunity of training the pupils to the work of the farm. In hay time and harvest they are made to assist the farmers of the neighbourhood, and thereby acquire some valuable experience. The system of agriculture taught is essentially local, that is, the practice recommended is that which is most suitable to the locality in which the school is situated. A circular has been issued inviting the municipalities to provide for every district a "demonstration plot" of not less than half an acre.

AGRICULTURISTS AND THE LAND.—The number of persons deriving their living directly from agriculture in France was 6,913,000 in 1886. Since the year 1862 the number has diminished 4 per cent. Among these are about 5,000,000 landowners, of whom about 60 per cent. cultivate the land themselves. That France is eminently the country of small holdings is shown by the following figures: Of holdings under 2½ acres the proportion is 38 per cent.; the holdings between 2½ acres and 15 acres constitute 46 per cent. of the whole number, and those which are above 15 acres and below 62 acres are only 6 per cent.

BERLIN, 18TH JUNE, 1888.

THE IRON MARKET.—The pig iron market in the Siegen district is depressed, owing to the high prices now ruling for coke and ore, to the small amount of export trade which is being done, and to the fact that local rolling mills are withholding their orders for the third quarter of the year. The demand for fine sheets is not sufficiently large to keep the works employed, and wholesale dealers are reluctant to give out orders. The export trade in this class of goods is also weak. The production of the works belonging to the Rhenish Westphalian pig iron syndicate during May showed an increase of 7500 tons of Thomas pig on the previous month, but the output of foundry and forge pig slightly decreased. Representatives of Krupp, of Essen, and of Borsig, of Berlin, have recently visited Ruhla, in Thuringia, with a view to consider the advisability of exploiting certain abandoned iron mines in that district which produce a very good quality of ore. The price of rolled iron in Upper Silesia is firm, and business in steel is brisk. It is proposed to erect some new smelting furnaces for zinc in this district, but the prices fixed by the zinc syndicate will not be changed. Tenders have been received at Magdeburg for a number of locomotives. The Alsace Engineering Company of Grafenstaden quoted £1,670 each for eight locomotives, and £1,540 each for a further lot of twenty; Messrs. Henschel, of Cassel, quoted £1,622. 10s. each for twenty; the Vulcan Works of Stettin quoted £1,625 each for twenty, and £1,515 each for a further lot of twenty-five. The steel works at Witten have received an order from the Belgian State railways for a number of axles at £11. 2s. 5d. per ton; the Cockerill Company made the next lowest offer. The Saxon Engine Works (formerly Rich. Hartmann), of Chemnitz, have received an order for nineteen locomotives for the Saxon State railways.

GERMAN IRON ABROAD.—The official statistics of the foreign trade in iron are now anxiously awaited and eagerly scanned when they appear, in order to learn the latest results of our endeavours to meet, on an artificial basis of prices, the cutting competition of our Belgian and English rivals in neutral markets. Every fresh issue of the Customs returns leaves this question wrapped in greater gloom. The following are the particulars of the export trade down to the end of April, compared with the corresponding period of last year: Pig iron, 45,767 (84,097) tons; scrap, 8606 (23,386) tons; half wrought iron, 8415 (15,820) tons; finished iron, 78,741 (94,353) tons; wire, 62,056 (89,591) tons; rails, 31,833 (52,104) tons; other railway iron, 11,995 (13,353) tons; manufactured goods, other than machines, 66,692 (56,460) tons; total iron of all sorts, 314,105 (429,164) tons, a decrease of 23·36 per cent. The total exports in April amounted to 87,091 tons, against 71,409 tons in March. In the four months' trade there is an increase of about 9000 tons in angles and plates, and a decrease of 25,000 tons in bars. The exports of wire nails amounted to 15,193 tons, against 12,406 tons last year.

TEXTILES.—The present condition of the hosiery trade in Saxony is not very satisfactory. The number of orders recently received is not sufficient to keep the factories employed, and certain classes of goods are being made for stock, whilst prices are as depressed as they were a few months ago. In the little business which is being done, black and striped goods are most in favour, and a few good orders have been received for children's hosiery, both in wool and cotton. Fairly remunerative prices are obtained for fancy articles and all the better classes of goods. Articles in fast colours and light silk gloves are in fairly good request, but the prices obtained are so low that even when manufacturers do a considerable business the profits are exceedingly small. The makers of twist goods are well employed in manufacturing the Lahmann cotton "reform" goods.

STREET LIGHTING BY ARC LAMPS.—Some time ago I reported the experiments which were made in Unter den Linden with arc lighting, to find the best disposition, number, height and power of lamps, &c. The installation of 126 arc lamps is now in progress, the cables being laid underground, and connected to the small central station in the Friedrichstrasse, which was established by the original Edison Company about four years ago, and was at first used for the supply of glow lamps only fixed in some neighbouring hotels and restaurants. Motive power is provided at the station by means of four high speed horizontal steam engines of the Armington & Sims type, but made by Messrs. Löwe, of this town. The present dynamo plant, consisting of four 500-light Edison dynamos, will be transferred to some other central station supplying glow lamps, and special Siemens arc lighting dynamos will be erected instead. The lamps will be grouped twelve or thirteen in series. Architects have been invited to send in competitive designs for the lamp posts. The present subscribers of the station will be in future supplied from the large central station in the Markgrafenstrasse, and the cables for connecting the networks of the two stations are now being laid.

VIENNA, 18TH JUNE, 1888.

THE IRON MARKET.—Business in the iron market has remained quiet since my last report. The most important event of the week has been the establishment of a syndicate of wire nail makers, and in addition to the rise of 16s. per ton advised last week, a further advance is likely to take place both in wire and wire nails. It is expected that a syndicate of cut nail makers will also shortly be formed, as the demand for this class of goods is at present brisk. Heavy sheets are in good demand, and this is greatly due to the fact that engineering works are well supplied with orders, and are making large purchases, thus depleting the existing stocks of heavy sheets. Waggon works are also better employed. The Bohemian Western Railway is on the point of giving out orders for the supply of 14 coal waggons with brakes, 56 coal waggons without brakes, 6 goods waggons with brakes, and 24 goods waggons without brakes. In Hungary the demand for bar iron has been greater than in the previous week, and the works are for the time being fairly well employed. Building iron and heavy sheets are also in better request, but castings are somewhat neglected. Crude iron is languid, but prices have not changed.

METALS.—Considerable activity prevails in the metal market, especially as regards copper, the price of which is again rising. Tin is somewhat neglected. Zinc is active at the previous week's quotation, and lead is advancing. The Nadelburger Metallwaren Fabrik is about to be enlarged by the addition of a special department for the manufacture of pins, and hooks and eyes. Hitherto the specialties of the works were metal articles, such as candlesticks, cutlery and plated goods, mortars, fittings for wells, &c., many of which articles are largely exported to America. The manufacture of special alloys to resist acids and other chemicals is also an important branch of business at these works, which were established 130 years ago, and employ about three hundred hands. The works have water power, and also two steam engines of, together, 340 h.p.

TEXTILES.—The present condition of business is not satisfactory. Cotton yarn is cheap, but spinners are reserved, and many are even selling their stocks of yarn instead of working them up. In linen goods, however, trade is somewhat better. The state of the market in Trautenau is more satisfactory, and the prices for linen yarn are higher than was expected. Woollen goods are firm; but in silk some reserve is shown. This is greatly due to the fact that the silk harvest will very soon be completed, and the results are anxiously awaited. At the Jubilee Exhibition, the cotton spinning mill of Harland, in Austria, is well represented. The owners have, in addition to the spinning mill, also a bleach works and twisting factory, and are, to a certain extent, competitors of English firms in foreign markets. At home, however, English competition is still too strong for them. This is the largest firm of the kind in this country, and the total steam power required in the various branches of their works reaches 800 h.p. Another fine exhibit representative of the Austrian textile industry is that of Messrs. Philip Haas & Sons, of this town, whose specialties are carpets and hangings. This firm have depôts in nearly all European capitals, and even in such remote places as Teheran, Smyrna, Calcutta, Alexandria, Cairo, and Jassy. They employ about 3000 hands in their various factories at home and abroad.

SWITCH BOARD FOR CENTRAL ELECTRIC LIGHT STATIONS.—The Allgemeine Elektricitäts-Gesellschaft of Berlin show at the Jubilee Exhibition a very compact switch board for central station work. The board is designed for seven feeder circuits, but only six of these are used in the electric light station at the Prater, which comprises one thousand glow lamps and one hundred 12 ampère arc lamps. The current is supplied by six dynamo machines to the switch board, from which radiate the mains to the rotunda, various transepts and pavilions, and to the two main avenues in the Prater, which are lighted by arc lamps. The board is supported on a stand which contains the resistances required for the regulation of the exciting current of the dynamos, and also the rheostats for the different feeders. The pressure on each feeder can be read off on a voltmeter provided with a multiple switch, and an earth on any circuit is automatically indicated in the usual way, with a lamp and bell. The switch board is chiefly remarkable for the close arrangement of the various switches, and for the small space occupied by the resistances, the whole apparatus being self contained.

BRUSSELS, 19TH JUNE, 1888.

THE COAL MARKET.—The market continues very firm, coal for industrial purposes being specially in demand. Large coal is quoted at 15s. 2d. to 16s. 10d., unscreened at 9s. 2d. to 10s., dross at 6s. 5d., coke dust at 7s. 2d., and coke at 12s. The number of waggons employed in the carriage of coal and coke on the State railways during the last week shows an increase, as compared with the corresponding week of 1887.

THE METAL MARKET.—There is not much change in the situation, prices being maintained and orders coming in satisfactorily. Complaints are still being made by those rolling mills which have no blast furnaces of their own as to the high price of pig, and they continue to agitate for a reduction of the import duties on the raw material. In the meantime the prices of coal, coke, and pig iron are all high; but as some contracts are being renewed at current rates, and English pig continues to arrive in large quantities, it is not probable that there will be any rise in pig for the second half of the year. Best girders are quoted at 96s., angle iron at 104s., and sheets at 120s. to 176s.

THE GLASS TRADE.—The situation in the glass trade does not improve. The American demand is limited, as there are considerable stocks in the United States. For the English market the following rates have been fixed; 20s. for coarse, 22s. for fourth, and 24s. for third quality.

TEXTILES.—There is little doing in Russian hemp, owing to the rise in the rate of exchange having forced sellers to raise the price. Home grown flax finds a sale at firm prices, but there is not much doing in linen yarn.

THE EXHIBITION.—The engines at the Exhibition are now all at work. Those driving the electrical machinery are distinct from those for the general machinery in motion. The main shaft in the electrical section runs at 110 revolutions, and the power is transmitted to a countershaft running at 250 revolutions a minute. The shafting, pulleys, &c., have been supplied by Messrs. De Naeyer, of Willebroeck. The electric lighting of the gardens and machinery section has proved very successful. There are forty Brush lamps of 10 ampères placed along the lawns, thirty Thomson-Houston lamps of the same power in the horseshoe arcades and the Salle d'Honneur, and eighteen Brush lamps are placed round the hippodrome. There are forty Pieper arc lamps for the lighting of the central promenade in the grounds and for the fountains. Four Brush arc lamps are employed to light the Bodega, and there are eight in the English section, and two at each of the toboggan slides. Twenty-four Pieper arc lamps are placed in and outside the casino, twelve in the Neubecker brewery, and ten in the grotto. In all there are about two hundred lamps in the gardens and outside the buildings. In the machinery section forty-eight lamps of 10 ampères are employed.

ELECTRIC LIGHTING.—The Société Industrielle d'Electricité have received the contract for lighting the Northern Railway Station at Brussels, for the lump sum of £2,400. The plant includes a Walschaert's steam engine of 100 h.p., working at 66 revolutions, and two Lahmeyer dynamos, one of 105 ampères at 115 volts, and one of 130 ampères at 115 volts. This contract gave rise to a lively competition among Belgian electrical engineers, as this installation is considered as an excellent advertisement for its contractor. The same company is undertaking the installation of the new military hospital at Brussels, the lighting being carried out by M. Sandron, who had charge of the electric lighting of the Courtrai railway station. Messrs. Mourlon Frères, in recent private installations, have been employing the Ship-

Digitized by Google

man steam engine, in connection with which petroleum is used as fuel. The engine is of the inverted type, mounted on the same bed plate with the boiler, which is a coil. The size of the flame is automatically regulated in accordance with the power required, and the combustion of the petroleum, which is injected in the form of a fine spray, is so perfect that no smoke is produced. The inventor claims that the consumption of petroleum is only 4lb. per h.p. hour.

Gas Lighting.—At Liège, the rates for the supply of gas were altered on the 16th inst., the price charged being now 10c. per cubic metre in the day, and 15c. during the night. The Wenham gas lamp, exhibited in the English section of the Brussels Exhibition, shows various improvements, resulting in greater economy of gas, whiteness of flame, and absence of smoke. The flame is more concentrated, and all the air necessary for combustion passes through channels heated by the escaping gases. This has the double advantage of increasing the temperature of combustion and of decreasing the heat radiated from the metal work of the lamp. At the same Exhibition there are also various samples of the Ezmos lamp on view, and a new burner of M. N. Rey, of the Compagnie Franco-Belge. Both these systems are now finding favour in Brussels.

DÜSSELDORF, 18th June, 1888.

The Iron Market.—On the whole no change has occurred in the market for iron since my last report. Business has become more slack in some classes of goods, but the loss in these directions is partly compensated by greater activity in others. There are no symptoms of serious weakness. The opinion gains ground, however, that the second half of the year will be a period of comparative quiet. The constant shrinkage in the foreign trade is making itself felt, and has a depressing influence. The pig iron market continues dull, buyers being very chary of entering into new engagements. The unanimous refusal of the blast furnace owners to grant any concession in price to the makers of finished iron who work for export has added to the feeling of apprehension with which the future is regarded. The demand for forge pig has further decreased. Spiegel is less inquired after, and basic steel pig is neglected. Bessemer pig continues to be bought, and foundry pig is still in brisk demand. The finished iron and steel trade is wanting in life. In bars, business has further declined. Prices remain firm, but the margin of profit is narrow. Some manufacturers have begun to restrict the make of bars. Stocks are, however, very low, and the common opinion is that as the season advances business will increase. The demand for boiler plates was very brisk at the beginning of the week, probably in anticipation of the rise of 5s. a ton which has just been declared. This advance raises the price of boiler plates to £7. 10s., and that of common plates to £6. 10s. Since the end of last year, forge pig has risen from 42s. to 52s.; bars from £4. 15s. to £6. 10s.; and boiler plates from £6. 15s. to £7. 10s. Sheets are but little inquired after. Wire remains unaltered. The wire nail syndicate is to be carried on for at least another month in the hope of inducing the outstanding Westphalian firm to join it. If this firm persists in its refusal to enter the syndicate, the latter must collapse.

The Linen Yarn Market.—Business in linen yarns is fairly active. The demand on the part of the hand weavers is light, but machine weavers have bought largely. The stocks in the hands of spinners are low and constantly diminishing. Prices are, however, kept down by the competition of foreign dealers, who press their goods for sale, especially in the Bielefeld market. Tow yarns are less inquired after. The net imports of flax in the four months ending with April last amounted to 294,150cwt., against 234,482cwt. last year. The net imports of linen yarn in the same time amounted to 60,156cwt., against 54,250cwt.

Water v. Railway Carriage.—Large quantities of iron ore are now being transported from the North of France to the German iron works on the Ruhr. The ore is conveyed by canal boats to Ghent and transferred into Rhine boats for transport to the ports on the Ruhr. Another instance of the successful competition of water-borne goods with those which have to be carried by railway may be mentioned, especially as it serves to enforce the arguments set forth in your leading article of the 18th ult. The German packing paper makers have a large and steadily growing market in England. The imports from Germany in the first four months of the current year amounted to 147,077cwt., against 129,855cwt. and 111,832cwt. in the corresponding periods of 1887 and 1886 respectively. Lately a large contract was obtained by a German manufacturer because the cost of carriage from Manchester to London is £1. 5s. 10d. per ton, while the freight from Hamburg is only 11s. 6d. per ton.

LILLE, 19th June, 1888.

Textile Manufactures.—The trade in textile goods shows no symptom of returning animation. The market is extremely sensitive to political influences. The death of the German Emperor has occasioned a further depression, buyers limiting their dealings to the wants of the moment, the future being regarded as very uncertain. A stronger tone of affairs is reported from Armentières, where linen goods are in better demand. The summer business seems to have now fairly set in. Fine cloth has advanced in price. The cotton trade of Rouen is still very quiet. There is, however, a steady though feeble current of business, and in the absence of political disturbances there is a fair prospect of activity next month, when the agents of foreign houses usually visit the place. The latest accounts received from Roubaix are less encouraging. The revival which showed itself a few weeks ago has been scarcely maintained. Numerous orders come to hand for fancy goods, but individually they are of little importance. At Calais the spring season has failed to fulfil the hopes of the manufacturers of tulle.

Flax and Yarn Market.—Only a small quantity of home grown flax has been offered for sale this week. There is but little available, and what there is left of last year's crop is firmly held. The higher prices quoted last week are maintained, notwithstanding the improved prospects brought about by the copious rains of the last few days. However favourable the weather may now be, it is certain that the plants can scarcely attain more than half their usual height. Russian flax has been less largely dealt in this week. The rise in the value of the rouble has compelled holders of flax to increase their prices about 1s. 6d. per cwt. Russian tows are in demand at higher rates. The animation which last week formed the distinguishing feature of the yarn market has somewhat abated, but business is by no means slack. The advance of 9d. per cwt. gained for the common sorts of linen yarns has been maintained. Most spinners having sufficient orders in hand for the next three months, no eagerness is manifested to push sales. Jute yarns are in brisk demand, and prices are very firm for all descriptions. The Belgian markets are active, and prices have an upward tendency.

The Iron Trade.—The iron trade of this locality offers no new features. Manufacturers have now abandoned the hope of a steadily growing current of trade, which seemed almost certain a few months ago; and consumers, anticipating a relapse, refrain from all dealings on speculative account. The wants of the moment are, however, considerable, and a large amount of business is transacted in most classes of iron. Bars are somewhat dull, and Paris merchants are buying but little; but joists are in fair demand, and plates are much sought after. Prices remain unaltered.

MADRID, 18th June, 1888.

Pig Iron.—Since the breaking up of the pig iron syndicate at Bilbao, prices have been gradually decreasing, and 46s. is now quoted for the best foundry pig. This rate leaves very little profit at the present high cost of coke. The first Simon-Carvés coke ovens in this country employing English coal will be started next month.

Antimony.—A new antimony mine has been opened in the province of Caceres. The ore appears to be rich, and it is anticipated that large quantities will shortly be produced and shipped from Lisbon. As the workings go deeper, it is expected that the ore will be found to contain a considerable percentage of silver.

Duties on Railway Plant.—All the important railway lines in Spain have had the right to import their plant duty free during the first ten years of their working, but a Bill has now passed the Senate prohibiting any such clause in future railway concessions. The duties charged are, however, very moderate. Locomotives under the general tariff only pay a nominal duty, which will leave the market open to English and German builders. The Bill will, however, probably have the effect of causing railway waggon works to be started in Spain, the duty amounting to £2 per ton weight. The best business would be done by a company with a large capital, which could let the waggons on the hire system to the many new local companies which will be formed to work narrow gauge railways. There is at present one waggon works at Barcelona; but its position is not favourable either for iron, steel, or fuel, and Bilbao would be found a more suitable site for such a business.

Patent Laws.—A Bill has been introduced into the Cortes to amend the patent laws, which are at present very complex and indefinite; but the changes proposed are not satisfactory, and do not appear to be calculated to simplify the existing state of confusion.

NEW YORK, 9th June, 1888.

The Coal Market.—The anthracite coal trade remains in about the same condition as a week ago. It will be a month before any active demand is likely to arise. June prices will remain unchanged, and there is little likelihood of an advance before the autumn. All the leading companies are supposed to be making an effort to restrict production, but notwithstanding this the supply considerably exceeds the demand.

The Iron and Steel Market.—The feeling of doubt and uncertainty in the iron market still continues. Prices are low, and little business is being done. Although there is some scarcity of good irons, yet production has not been brought down to a level with consumption. The average supply is in excess of the demand; the outlook as regards consumption is far from encouraging, and during the next three months is certain to be much less than during any corresponding period for a long time past. Several additional furnaces will soon be at work in the South, so that the present indications point to an increase in the supply rather than to a decrease. Consumers are buying very sparingly, so that the natural shrinkage in consumption is intensified by the determination not only to buy as little as possible, but to carry as little stock as possible. Prices of pig iron are unsettled, and there is no pretence of uniformity except in mill irons, which have not been reduced in proportion to foundry grades. Consumers have no confidence even at the present low quotation, and except for stock immediately required, they are not in the market. The usual quotation for this class of iron is from $16 to $17 per ton, the latter price being for special brands. The Andover furnaces are all out of blast, and as the Glendon have only one in operation, high grade mill irons are becoming scarce. There is an ample supply of lower qualities, but it requires careful selection to secure a fairly good average mixture at $16. There is plenty of iron at $15 to $15·50, but there are no buyers for this quality. The position is somewhat different in foundry grades, the supply of which is fully up to the demand. As there is plenty of iron, it is difficult to arrange prices in proportion to quality, and yet meet buyers' demands. The Thomas Iron Company's quotations are not being met by the trade, those controlling brands of an established reputation claiming to have a demand for all they can spare at higher prices, some getting $18·50 for No. 1, some $19, and some more. The prospect is that good foundry irons will maintain their present position during the summer, and that lower qualities will be weak and irregular, with special low rates to those taking large lots. There is no improvement in manufactured iron, although the demand is fair. With so many mills waiting for work, the market is in a very dull condition. Although prices are no lower than they were some days ago, it is difficult to secure business without yielding somewhat in the buyer's favour. For the next two or three months a very dull season appears to be inevitable. Prices are about 1·8c. to 1·85c. per lb. for bars, 2c. to 2·1c. for plates and angles, and 3·3c. for beams and channels. There is very little doing in steel rails, but the demand for blooms and billets in some measure compensates for the loss in that direction. Prices are nominally $31 to $32 per ton at the mill, but only small lots are taken, so that it is hard to say what would be accepted for a large order.

The Metal Market.—The copper market is quiet, and prices are steady at about 16·6c. per lb. Quite a large stock is accumulating here, which will probably amount to 25,000 tons by the end of the summer, and this is causing some uneasiness as to the future condition of the market. A moderate amount of business has been done in tin, at prices ranging from 19·50c. to 20c. per lb. for spot. The demand for tin plates continues good. The lead market has been a little more active. The spelter market is better, advancing slightly on the news that several Western mines were flooded. Quotations are 4·6c. to 4·75c. per lb. for common domestic.

Electric Railways.—There are now 130 miles of electric railways in operation in the United States—an increase of fifty miles in less than six months. The maximum mileage in any one State is twenty-one in Pennsylvania. There are now sixty-two different roads in operation or nearing completion, and of these seventeen are on the Van de Poele system, fifteen on the Daft, and seven on the Sprague system; the remainder being divided amongst a number of companies.

Glow Lamps.—Lieutenant Hutchins, of the United States Navy, has been making a number of experiments as to the risk of explosions when incandescent lamp globes are broken in explosive mixtures. The first experiment was made with a mixture of hydrogen and oxygen, Swan lamps being used. When the glass was broken the mixture exploded, but the filament was unbroken. The second experiment was made with marsh gas and air, when the filament was broken. Another experiment was made with coal gas, and after the bulb was broken the gas burned for some time. An explosive mixture of coal gas and air was next experimented on, and exploded after the breaking of the bulb. As it is claimed that the breaking of the bulb of an Edison lamp will always break the filament by the first rush of air, the same danger would not attend the use of the Edison lamp as is shown to be the case with lamps of stronger filaments. But even if all were equally dangerous in explosive mixtures, the liability of broken lamps and dangerous mixtures occurring at the same time is very slight.

PHILADELPHIA, 9th June, 1888.

New Steel Works.—Mr. John Birkinbine, of Philadelphia, has completed all the plans for blast furnaces, steel converters, and mills for the Duluth Steel Company, and work has commenced on the foundations for the 140-ton blast furnace, to be followed at once by the casting, stock, and engine houses. The works is not expected to be ready for business before the opening of lake navigation in 1889. The ores to be used are the Bessemer ores of the Vermillion, mixed with the softer ores of the Gogebic range. The plant will cost about £400,000.

A New Galvanometer.—Messrs. Geyer & Bristol, of Stevens' Institute of Technology, have constructed a new galvanometer which indicates the strength of current by its heating effect on a compound bar made of the same metal. The bar is bent into an arc of about 270°, and consists in reality of two bars joined at one end, but otherwise insulated from each other throughout their entire length. They are made of such shapes and sizes that the two parts of the compound bar are unequally heated by the current passing through the bars in series. Gearing is arranged so that the deflection of the pointer is in direct proportion to the current flowing. With the dial removed the apparatus looks not unlike a Bourdon steam gauge.

RICKINSON'S IMPROVED CASTORS.

The ordinary method of fastening castors to the legs of chairs and tables is admittedly very imperfect. The castor is generally attached by two or three little screws, which are easily wrenched out of the wood, and when this happens it is difficult to find a new place for the screws by the side of the holes from which the threads have been torn. To obviate this difficulty, Mr. H. Rickinson, of Birmingham, attaches the castor by means of a separate sleeve, as shown in our illustrations. The leg of the chair or table is either undercut conically, as in Fig. 1, or a collar is left, as in Fig. 2. Round this collar or cone there is first placed a ferrule A, with a screw thread on the

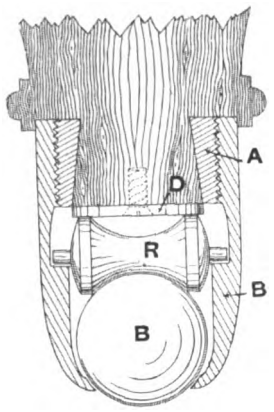

Fig. 1.

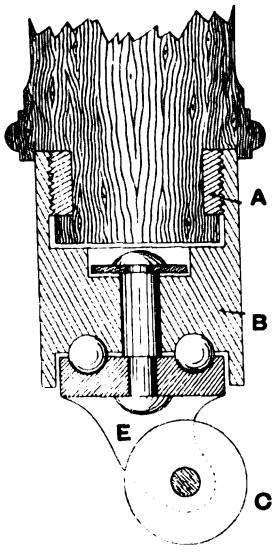

Fig. 2.

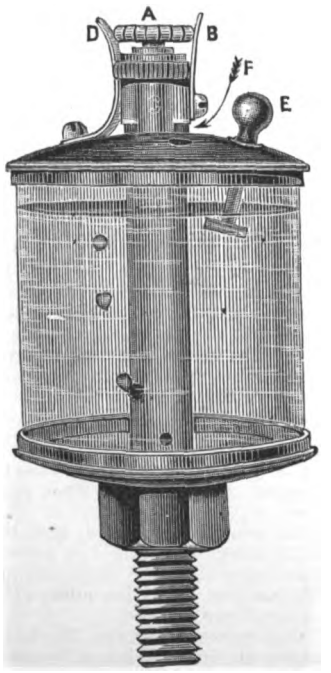


outside. This ferrule is in halves, and over it is screwed the casting B, which is thus secured to the leg in a substantial manner. The castor shown in Fig. 1 consists of a ball B and roller R, upon the latter of which rests the end of the leg, which is provided with a washer D. The roller is turned to the radius of the ball, and is confined by a small ledge within the casting B, upon which the ends of the axis of the roller rest when the leg is lifted. If the leg is pushed along the floor in a direction at right angles to the surface of the paper, the roller R simply revolves, its axis remaining in the position indicated by the sketch. If, however, the leg is pushed slantingly, the rotation of the ball causes the roller itself to turn round so as to place its axis at right angles to the direction of movement, thus always producing a true rolling motion without grinding. In the castor shown in Fig. 2 a ball bearing is used to diminish friction. The roller C is of the ordinary type, but smaller, and held in a bracket E, which is secured to the casting B by a central pin. This is a slack fit in the casting, and only serves to prevent the castor from falling off. The weight is taken by three or four little balls, confined between semi-circular channels, as shown. By this means the castor is made to run very easily, and it is thus possible to bring the centre of the roller C very near to the centre of the leg.

BOILER EXPLOSION NEAR SEAHAM HARBOUR.

About half-past eleven on Wednesday morning, the 13th inst., one of the boilers working at the Murton Colliery, which is situated near Seaham Harbour, exploded. The boiler formed the third in a range of seven used to supply steam to the winding engine of the middle pit. It was of the plain cylindrical externally fired type, with hemispherical ends. The boiler was 30ft. in length, 8ft. diam., and made of plates ⅜in. thick, which were arranged with their longitudinal seams in line for the whole length of the boiler. Each ring was also made of very small plates, each 4ft. 6in. in length and 2ft. in width, there being no less than thirteen plates in each ring. The boiler was provided with the usual mountings, and the safety valve loaded to 30lb. per square inch. The boiler, we understand, was made about the year 1859, and was insured by the Newcastle Boiler Insurance Company. The boiler does not appear to have suffered from corrosion, and although much patched, appeared, considering its great age, to have been in fair condition. Rupture appears to have first taken place at the longitudinal seam of the left side of the boiler near the seating, and the boiler appears then to have torn in three pieces. One portion, about 9ft. from the back end, was blown over the engine house, falling on the top of the winding gear of the Polka Pit, where it remains lodged. Another and larger portion was forced forward through the engine house wall, which was 3ft. thick, and the third piece was thrown over and upon the coal screens. The safety valve weight was thrown 150 yards away, passing through a coal waggon in its descent. Although the pressure at which the boiler was worked was a very low one, it would appear to have been too much for this boiler, which was about thirty years old, and constructed in an extremely weak manner, rendering it liable to disastrous explosion, as in the event of even a small fracture occurring in one of its longitudinal seams, the immediate tendency would be for such a fracture to run the whole length of the boiler, as when a woman rends a piece of calico, by commencing the tear with a short snip. Little reliance can be placed on boilers constructed in this manner, particularly when of the plain cylindrical type, and unsupported either by stays or internal flues; and we think very few boilers of this type are now under the charge of the Boiler Insurance Companies, or even in use, as we believe it has been the custom for many years of the principal companies to avoid where possible the insurance of boilers of a similar type. Nine workmen were injured by the explosion, the fireman severely. As this accident occurred at a colliery, the examination of the boiler will not devolve upon the engineer officers of the Board of Trade. An inquiry may probably be held, however, under the Coal Mines Regulation Act.

QUIGGINS' SIGHT FEED LUBRICATOR.

The accompanying illustration shows an improved sight feeding lubricator recently introduced by Messrs. R. Shone & Co., Liverpool. The lubricator consists of a glass cylinder with a brass cover and bottom, which are pressed against the glass cylinder by means of a nut on the tube passing through the lubricator, an air tight joint being made by means of washers. The brass tube is provided with air holes and oil inlets, and carries a regulating valve A which is locked in position by the spring B. The air enters the lubricator at F, and appears in the form of bubbles at the air holes of the tube. If it be required to

shut the oil supply off, the spring D is forced backwards, and the cap turned until it drops into a recess provided in the cover. A flush of oil may be given by raising the cap bodily off the cover, when the oil will flow as long as the cap is held in the raised position. Neither the cutting off nor the flushing operation interferes with the position of A, so that the lubricator will supply oil at the same rate until the position of A is altered. For filling the lubricator the cap is placed in the recess of the cover, the plug E is partly drawn out, and the oil introduced through the plug hole. The cap is then raised until the spring D drops into the recess provided in A, when the lubricator will begin to act. The advantages claimed for this arrangement are as follow: The lubricator requires no gear or moving parts for working it; the amount of feed may be regulated to any required number of drops per minute, and the supply of oil may be shut off or a flow of oil given without interfering with the adjustment of the regulating valve. The rate of oil supply is indicated by the air bubbles ascending through the oil, which also show if the lubricator is working, and the amount of oil left may be seen at a glance. The makers claim that this lubricator works equally well either on the moving or stationary parts of machines.

PEAT MOSS LITTER.

The manufacture of peat moss litter has, of late years, become an industry of considerable importance, notably in Germany, where in the neighbourhood of large peat fields special factories have been established for cleaning and compressing the peat moss into bales, which are now regular articles of commerce, and a considerable number of which is imported into Great Britain. Large peat fields occur in Holland, Friesland, in the district of Hanover, in the province of Pomerania, in the South of Bavaria, near the lake of Constance and the rivers Lech and Isar; also in Bohemia, and in Scotland. The deposits in peat fields consist generally of three layers: the upper of humus, which supports a scanty vegetation, but is otherwise of no value; the middle layer of peat moss consisting of a more or less open and fibrous agglomeration formed of the roots and other parts of plants; and the lowest layer, which is peat proper, and which forms in many districts the only available fuel. Previous to the present decade the occurrence of peat moss was considered an unmitigated evil by peat cutters, necessitating as it does a great deal of labour before the peat is reached. In some cases, the peat moss was used as a very inferior kind of fuel; but generally it was simply thrown aside as useless. The credit of having discovered a use for this material belongs to a German, viz., Herr W. Hollmann, who in 1880 hit upon the plan of utilising peat moss in lieu of straw or chaff as a litter, and who erected a factory on a peat field in the neighbourhood of Brunswick. The remarkable hygroscopical qualities of peat moss had previoulsy been pointed out by Professor Virchow, and it was this property of absorbing large quantites of moisture, and also gases, which first directed the attention of Herr Hollmann to a possible use of this material in stables, and as a vehicle for natural manure. His first experiment in the utilisation of peat moss was financially and technically so successful as to induce many other persons to erect peat moss factories in various places in Germany; but some of these proved failures, as the success of such undertakings depends very much on local circumstances, and on the best selection of a site.

The importance of the peat moss industry is two-fold. In the first place a valuable material is produced with comparatively small working expenses; and in the second place, the fact that a purchaser can be found for the peat moss overlying the more valuable peat, renders the cutting of peat profitable, even in such localities where otherwise the great expense of removing the upper layers would render the exploitation of a peat field financially impossible. Some of the German peat fields have a depth of from 12ft. to 20ft., and it is evident that unless the greater portion of the material to be dug out can be utilised, the operation would not pay. Peat cutting, as now carried on in the fen districts of Holland, has besides its industrial, also an agricultural value, since large tracts of land, which formerly only supported a most meagre vegetation, are by its means rendered productive. To exploit a peat field, the first step taken by the peat cutter is to dig a main canal, which not only provides a waterway to the nearest town, but also serves as an outlet for the subsidiary canals which are dug for the purpose of draining the field. To properly locate these canals a preliminary survey is required, but the unstable nature of the ground makes it necessary to take special precautions in carrying out this work. The main canal, as already stated, serves as an outlet for the drainage of the field, and at the same time as a waterway for transporting the peat and peat moss to the town, the barges bringing back manure, which is mixed with the humus and incorporated with the sand left after the peat has been removed. By degrees the ground thus prepared becomes fit to produce green or cereal crops. Where, as in Germany, waterways are not abundant, the factory for peat moss litter must be erected on the peat field itself or in its immediate neighbourhood. When on the peat field, it must be placed on its highest point. The bricks of peat moss are first stored in a wooden shed open on the weather side, and provided with a flooring a few feet above the ground. If the bricks were laid on the ground it would be impossible to thoroughly dry them, as they would always absorb moisture from below. A light railway runs through the drying shed into the factory proper, where the peat moss is passed

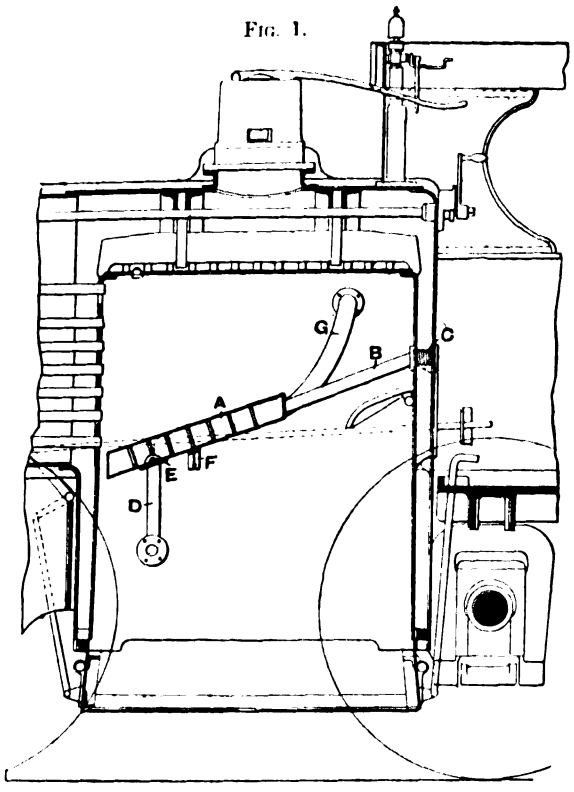
Digitized by Google

through a "devil," which opens out the fibres, and thus effects a preliminary separation of the earthy and vegetable matter. The separation is further carried on by means of a series of sieves, and the resulting woolly material is then passed into bales varying in weight from 1½cwt. to 4cwt., in which form it is brought into commerce.

IMPROVED FEED WATER HEATER.

Our illustrations show a locomotive feed water heater, invented by Messrs. C. A. Haworth and I. Mason, Grey Mare Iron Works, Bradford, Manchester, which is intended to take the place of the brick arch now in use in locomotive fire boxes. The feed water heater A is connected to the injector or feed pump by means of the tubes C and B, and the heated water is conveyed into the boiler

Fig. 1.



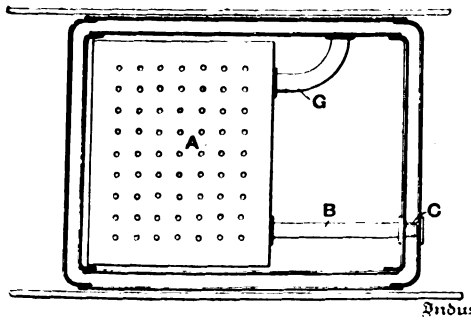


Fig 2.

Industries.

through the tube G. A valve E is provided on the tube D, which prevents the feed water from entering the boiler, but allows free circulation of the water in the boiler through D into A when the engine is standing, thereby keeping the temperature in boiler and feed water heater uniform. The apparatus is supported on a bracket F and the tube D. The advantages claimed for this arrangement are that it may be fitted to locomotives without interfering with existing connections, that it may be easily removed in case of repairs of the tubes or fire box, and that the heat now absorbed by the brick arch may be used for raising the temperature of the feed water to about 300°F., thereby effecting considerable saving in fuel. We understand that this feed water heater has been used with good results on board the steam launch "Fawn."

Electric Lighting.—The contract for the plant and materials required for lighting Gedney's Channel, New York Harbour, with incandescent lamps on buoys has now been given out. There will be required 32,000ft. of three-wire conductors to connect the first two buoys, and 15,000ft. to connect the other four buoys with the three-wire circuit. The return will be on the iron armour of the cables. The Edison Company have been awarded the contract for the dynamos, lamps, &c. The cost of the plant will be £5,200, and the estimated cost of maintenance £600 per year.

SHIPBUILDING NOTES.

The "Kaisong," a screw steamer of 1650 tons, sister ship to the "Sung-Kiang," launched a month ago, left the ways at Messrs. Scott & Co.'s yard at Greenock, on Tuesday, the 12th inst. The "Kaisong" is built to the order of the China Navigation Company. The engines will be of 1000 h.p., and will be of triple expansion type.

The "Leon y Castillo," a screw steamer, for mail service between the Canary Islands, was launched on Friday last, by Messrs. David J. Dunlop & Co., Port Glasgow. The "Leon y Castillo" is 190ft. long, 27ft. broad, and 13ft. deep. The owners of the vessel are the Compania de Vapores Correos Interinsulares Canarios. She is fitted up with the electric light, and is luxuriously appointed for passenger service. The engines are of the triple expansion type.

On the 16th inst., at the yard of Messrs. C. S. Swan and Hunter, shipbuilders, Newcastle, a steel screw steamer, the "Avalon," was launched, of the following dimensions: Length, 380ft.; breadth, 37ft. 6in.; depth, 21ft. 8in. She has been built under special survey, and her construction throughout has been superintended by Captain Henry Towhill, of Liverpool. The "Avalon" is owned by Messrs. C. T. Bowering & Co., of Liverpool, and is built on the cellular bottom principle, with web frames in way of bulkheads, having bridge amidships, raised quarter deck, and topgallant forecastle. The vessel will be classed 100 A1 at Lloyd's, and fitted with four steam winches, steam steering gear, and stockless anchors to draw into the hawse pipe. Her engines, which have been supplied by Messrs. Blair & Co., Limited, of Stockton-on-Tees, are capable of indicating about 1100 h.p.

Notices of Meetings.

THIS WEEK.

Physical Society.—Saturday, 23rd June, 3 p.m. "Note on Continuous Current Transformers," by Professor S. P. Thompson, D.Sc.

NEXT WEEK.

Royal Institute of British Architects.—Monday, 25th June. Ordinary meeting. Ballot for new members. Presentation of medals, &c.

Royal United Service Institution.—Friday, 29th June, 3 p.m. Paper to be read on "The Defence of our Mail Routes in War," by Captain Sir J. C. R. Colomb, M.P.

PRICES CURRENT, 21st June.

Quotations at per ton, unless otherwise specified.

Messrs. Carrick & Brockbank, Manchester, report as follows:—

Copper.—There is nothing new to report in the position of this metal. Quotations for Chili gobs spot parcels keep steady at about £82. 10s. per ton, with a margin of 5s. per ton either way, and with very little business doing except on syndicate account. Three months is quoted about £4 per ton less. Consumers appear to be still able to draw their limited supplies from outside sources over which the syndicate have no control. The export trade in manufactured appears to have gone "spark out," and it is reported that many of the Eastern markets are importing steel enamelled goods to replace those formerly made of copper. A large quantity of old copper is being shipped from the East for sale in France and England, and this is going forward for re-manufacture. The present unfortunate position of affairs is ruining the copper trade altogether, and it must end in disaster to those who have brought it about.

Tin.—Quotations are lower all round. Straits sharp cash parcels, £79. 15s. to £79. 17s. 6d.; English, £88. 10s. to £89. 10s. per ton.

Lead easier. Spanish quoted £12 to £12. 2s. 6d. per ton.

Spelter is again lower; warrants, £15. 5s. to £15. 10s. per ton

Zinc Sulphate ton	7	10	0	—	8	5	0

Messrs. S. W. Royse & Co., Manchester, report as follows:—

Business in chemicals is quiet. Alum is in moderate demand. Bleaching powder and caustic soda are both easier, but soda ash maintains its position. Sulphate of copper is steady. Muriate of ammonia is asked for, and makers are well sold. Carbolic acid is weakening, also oxalic. Sulphate of ammonia is steady.

Erratum.—Professor S. P. Thompson requests us to make the following corrections in our article headed "The Physical Society," which appeared on page 549 of the present volume. For $P = b K \sqrt{A} \sqrt[4]{\frac{L}{A}} \cdot \frac{L}{l}$ read $P = b K \sqrt{A} \sqrt[4]{\frac{L}{\sqrt{A}}} \cdot \frac{L}{l}$, and for tension in "degrees" per square centimetre, read tension in "dynes" per square centimetre.

HOME INDUSTRIES.

MANCHESTER, 21st June, 1888.

The Cotton Trade.—It is probable that the usual attempt will be made in Liverpool and New York to raise the prices when the close of the delivery of last year's cotton crop approaches. It rests entirely with the buyers of cotton whether the prices shall be raised or not; for if they buy freely and in excess of actual requirements such a course will be inevitably followed by a period of excessive rates. There is a large increase in cotton deliveries as compared with last year's, and there appears to be no reason to anticipate any scarcity until the end of the season. Spinners find it very difficult to effect sales at any advance on their prices, and they are quite unable to accept many large offers which are coming from the Eastern markets. The extremely low value of the rupee causes Indian and Chinese buyers to telegraph offers that are much below anything which the spinners can accept. The result is that a great amount of business cannot be accepted, and as long as the great majority of spinners remain so well under contract there is no probability of a fall in the prices of yarn. The chances at present are decidedly in favour of the spinners. The various wages disputes which have been disturbing the business of this district for some time past are now practically settled by a general advance of 5 per cent. in the wages of operative spinners. Fine counts of yarn are in active request, and the rates are fully maintained. In the cloth trade the influence of the increasing productive power is now being felt, and the low offers which come from the East are being in some cases met. In several districts round Manchester there are a good many looms standing.

The Employers' Liability Bills.—The United Cotton Spinners' Association has presented a petition to Parliament objecting to several clauses which are proposed for insertion in the new Bills before Parliament. Firstly, against the clause extending the time of giving notice of an action from six weeks to three months, on account of there being no good reason why such an extension should be granted. Secondly, against the proposed extension of the liability of the employer to the acts of all his employés, as it would lead to compensation being paid by employers for the acts of persons to whom they had delegated no authority. Thirdly, against the extension of the limit of compensation of three years' wages if not more than £150, to £150 or three years' wages, whichever may be the greatest.

The Metal Trades.—The iron trade has improved so far as quoted rates are concerned, but there is not much increase in the transactions in pigs. Buyers only purchase small lots, and there are complaints that specifications for contracts are hard to obtain. There is no sort of speculation existing in this market, and a period of steady business with fluctuating prices may be looked for until the autumn "boom" sets in. Wrought iron remains quiet, and common bars continue to fall in price. Although £4. 17s. 6d. per ton less 2½ per cent. is quoted as a minimum rate, plenty of iron can be obtained at lower prices, as there is a tendency in certain quarters to "bear" the market. Steel is in good demand all round; but the requirements in plates outside this district appear for the moment to have been satisfied, and there is consequently a fall in boiler plates of quite 7s. 6d. per ton. For this step there does not appear to be much justification, although it is fully appreciated by purchasers. There is a stagnation in the other branches of the metal trade, notably in copper. It is now practically impossible to find customers for any large quantities of copper or tin, and there is a prevailing expectation among consumers that a period of lower prices is not far distant. Business is seriously checked at present, and the conduct of the smelters with regard to manufactured copper is helping to add to the confusion. With a nominal price of £88 per ton for sheets, as low as £84 has been accepted, and it is stated that even lower rates for good lots would not be refused.

LONDON, 21st June, 1888.

The Money Market.—The tone of the money market has become still duller, and it is hardly possible that rates can recede much further, or the demand shrink to any greater extent. The supply of floating capital seeking for employment is excessive, and there is no outlet for it of any importance. The stock markets have had a better tendency since the death of the Emperor Frederick, and the greater vigour which has been infused into the political situation has favourably influenced the business in stocks. Foreign securities are in general much firmer, those styled "international" showing the most marked improvement. This is a practical proof that the capitalists do not anticipate any disturbance of European peace as the result of the accession of the Emperor William II. At home the improvement in the stock market is more of feeling than of actual prices. British Government securities are more freely bought, and there is substantial though not extensive buying of the stocks of the heavy or investment home railways. The unsettled weather has depressed the passenger lines, whose traffic returns show at once the effect of such adverse influences. The American railway market is fickle, though more disposed to rise than otherwise. The expectation is that within the next month these securities will improve in price, and will then fall away again in the autumn. The commencement of the Presidential campaign will injure business in the United States. There is little doing in mine shares, and diamonds are uncertain. The outlook in the copper market is doubtful; but it is considered good policy to buy cheap gold shares at present—not at random, of course, but with respect to the character of the mines. The alluvial mines of Colombia are in growing favour, as the results have been extremely good.

Companies.—The following new companies have been registered since our last report: Easton & Anderson, Ld., with a capital of £250,000, to carry on business as engineers, &c., in London and at Erith; The Manchester Engineering Company, Ld., with a capital of £10,000; Edward Young and Co., Ld., with a capital of £150,000, to carry on business in Liverpool as distillers; The D'Humy Cabinet Battery Syndicate, Ld., with a capital of £15,000; The Spontaneous Steam Generator Company, Ld., with a capital of £10,000, to acquire certain patents; The Tirydail Tin Plate Company, Ld. (Duffryn, Carmarthenshire), with a capital of £20,000; Perkin & Co., Ld., with a capital of £8,000, to carry on business as engineers in Leeds; The Dee Oil Company, Ld., with a capital of £100,000; Beverley Brothers, Ld., with a capital of £100,000, to carry on business as brewers at Wakefield; The Burton Brewery Company, Ld., with a capital of £250,000; Luther Hanson and Co., Ld., with a capital of £7,500, to carry on business as electrical engineers at Halifax; Automatic Electrical Corporation, Ld., with a capital of £75,000, to undertake the supply of electricity for lighting and other purposes in the United Kingdom; The Manchester Chamber of Commerce, Ld.; The Sydney Godolphin Tin Mine, Ld. (Cornwall), with a capital of £20,000; The United Anthracite Collieries, Ld. (Glamorganshire), with a capital of £25,000; and Phosphate Mining Company, Ld., with a capital of £100,000.

Railways.—The gross receipts of the twenty-three principal railways in the United Kingdom for the week ending 10th June amounted to £1,223,657 on 15,862½ miles, as compared with £1,189,122 in the corresponding period of 1887, when the mileage was 15,742½ miles. An increase is thus shown in the mileage of 120 miles, or 0·7 per cent., and in the receipts of £34,535, or 2·9 per cent.

The Navy.—The steam trials of the turret ship "Victoria" were made at the Nore on Tuesday and Thursday of last week. The vessel has been fitted with twin screw triple expansion engines, by Messrs. Humphrys, Tennant, & Co. The cylinders are 43in., 62in., and 96in. diam., and 4ft. 3in. stroke. The first day's trial was with natural draught, a four hours' run being made with the following average results: Steam pressure in boilers, 131·16lb.; vacuum in condensers, 27·8in. and 26·8 in.; revolutions, 87·3 by the starboard and 88·5 by the port engines; i.h.p., 3855·9 starboard and 4182·1 port, giving a total of 8038 h.p., or 538 h.p. in excess of the contract power, which was 7500 h.p. The mean speed was sixteen knots. The average result of four hours' steaming on Thursday with forced draught gave the following results: Steam pressure in boilers, 133·41b.; mean air pressure in stoke holes, 1·97in. of water; vacuum in condensers, 27·4in. and 27in.; revolutions, 101·26 by the starboard and 100·37 by the port engines; i.h.p., 7107·67 starboard, and 7136·86 port, giving a total of 14,244·53 h.p., or more than 2244 h.p. in excess of the contract power, which was 12,000 h.p. The average speed was over 17¼ knots, and 2lb. of coal per i.h.p. were consumed per hour.—The torpedo cruiser the "Racoon" was taken out of Plymouth last week for a four hours' trial of her engines. Everything proceeded very satisfactorily until the seventh trial, when the port engine broke down. The belted cruiser "Aurora" has made a successful trial of her machinery at Plymouth. The total i.h.p. was 5670, the speed attained being 17·25 knots.—A battery of forty of Drake & Gorham's latest type of ship lighting cells is to be supplied for lighting the Queen's yacht the "Victoria and Albert," which is now in the hands of the Admiralty.

Institute of Chemistry.—A soirée was given last week at Marlborough Rooms, by Dr. James Bell, the President of the Institute of Chemistry. There were numerous exhibits, which included many of those shown at the conversazione of the Royal Society, and of which an account was given in *Industries* of the 18th May last. Mr. T. Fletcher, of Warrington, sent his oxy-hydrogen blow pipe: the Badische Anilin-Fabrik, Messrs. Boulton and Co., and Messrs. Brooke, Simpson, & Spiller, exhibited samples of coal tar colours, and Brin's oxygen apparatus was shown at work.

The Royal Society.—The list of the gentlemen who were elected Fellows of the Royal Society, on June 7th, included the names of Mr. Charles Vernon Boys, Professor John H. Poynting, and Mr. William Henry White, M.Inst.C.E.

The Paris Exhibition.—The General Committee of the British Section of the Paris Universal Exhibition, 1889, has been registered under license of the Board of Trade and limited by guarantee. The object is to promote commerce and art by securing the due representation of British industries, commerce and art, at the Paris Universal Exhibition, 1889; to aid, represent, and assist British, Irish, Indian, Canadian, and Colonial exhibitors at the said Exhibition, and to secure combined action amongst such exhibitors; to negotiate and correspond and arrange with the French Government and its representative commissioner and agents of and in relation to all questions concerning Great Britain, Ireland, the Empire of India, the Dominion of Canada, and the English Colonies in connection with the Exhibition, notably those relating to the distribution of space, the manner of installation of and payments to be made in respect of the British section; to prepare and publish a catalogue in English of the British section, and to do all such other lawful things as are incidental or conducive to the attainment of the above objects or any of them.

Arts and Crafts Exhibition.—An exhibition is to be held under this title at the New Gallery during October and November this year, at which will be shown work done by designers and craftsmen. Exhibits are divided into the following twelve sections: Textiles; gold and silversmiths' work, including enamelling; metal and iron work; decorative paintings; wall papers; bookbinding; printing; glass; stained glass; wood and stone carving; and cabinet making. A guarantee fund is being subscribed in connection with this undertaking, and further information respecting the Exhibition may be obtained from Mr. Ernest Radford, 121, Regent-street, W. Forms of applications to exhibit must be filled up and sent in by the 30th instant.

GLASGOW, 21st June, 1888.

Shipbuilding.—A number of new orders have been placed during the past few days. Among these there is one for a tank steamer of 4000 tons, for the petroleum trade, to be built by Messrs. A. and J. Inglis, Pointhouse; and one for a small steamer, to be built by Messrs. R. Napier & Sons. It is reported that Messrs. Alex. Stephen and Sons have contracted for a large screw steamer. A schooner yacht, with auxiliary screw, named the "Garland," built by Messrs. Ramage & Ferguson, Leith, for the Hon. Mrs. Elliott Yorke, has just been finished. The "Garland" is handsome in outline, and is luxuriously fitted up. She is 124ft. long, 21ft. 6in. broad, and 13ft. 6in. deep. The triple expansion engines are of 280 i.h.p., and are fitted with Messrs. Ramage & Ferguson's new valve gear. The cylinders measure respectively 11½in., 18½in., and 30in. The boilers are intended to work up to 150lb. pressure, and they are fitted with Brown's patent annular ribbed furnaces. The windlass is Messrs. Napier Brothers' steam capstan.

Coal Shipments.—This year's coal shipments from the Clyde are still keeping far ahead of the corresponding exports for 1887. In spite of a slight falling off last week the relative figures for the five months and a half are 1,932,786 tons, against 1,178,761 tons, or an increase of 750,000 tons.

The Central Railway Bill.—The House of Lords' Committee, presided over by Lord Auckland, has found the preamble of the Central Railway Bill proved subject to slight modifications of clauses. The new Central Railway line will start from the extreme east of Glasgow, and passing under the principal street of the city, Argyll-street, throughout its whole length, will extend beyond it and will pass to Stobcross Docks, whose traffic has hitherto been practically monopolised by the North British Railway Company, as the access to the docks to the Caledonian is only available on payment of wayleave to the North British Company. This railway will also give the Caledonian Railway a hold upon the traffic in the west end of Glasgow generally. The promotion of the Bill has, of course, been suggested by the success of the City and District Railway, whose underground trains are among the best paying in the system, in spite of many drawbacks, such as deficient ventilation of the tunnels, &c.

New Gold Process.—The commercial column of the *Glasgow Herald* has been the means of announcing the patenting of a new process for the recovery of gold from refractory ores. The process is said to be the discovery of Mr. J. H. Pollok, assistant to Professor Ferguson, professor of chemistry in Glasgow University. The cost of materials for extraction is stated to be 4s. 6d. to 6s. per ton. In addition to this process there has also been recently developed in Glasgow at least one other process whose features are apparently similar to those of the process above mentioned, and which, though it has been hitherto kept in reserve, has actually been worked upon a scale sufficiently large to demonstrate its practicability.

Glasgow International Exhibition.—The beautiful weather has had a good effect upon the attendance at the Exhibition. The numbers on Saturday last were larger than on any previous occasion, 64,880 admissions being registered. The average daily attendance, exclusive of Saturdays, remains about 26,000, the Saturday admissions bringing the average up to about 34,000 per day.

(From our own Correspondents.)

LIVERPOOL, 20th June, 1888.

The Water Famine in Liverpool.—Although the usual constant supply of water to the city was reduced some months ago to an intermittent supply of twelve hours daily, and although the streets are now watered entirely with salt water obtained either from the docks or from the drainage of the Mersey Tunnel, the Water Committee have resolved, on account of the very low level of the water at Rivington, to further restrict the supply to six hours per day.

Serious Subsidence in Dale-street.—An extraordinary cavity, about 14ft. square and 7ft. deep, was found last week under the tram lines in Dale-street, the only thing which sustained the traffic being the concrete foundation of the roadway. Wooden tracks were laid to bridge over the opening for the tram traffic; excavations are now proceeding to ascertain the cause of the subsidence, and although the workmen have descended almost 30ft., no solid bottom has yet been reached.

Digitized by Google

SHEFFIELD, 20th June, 1888.

Iron and Steel.—The prices of iron continue to be very easy. Foundry pig can be bought at from 34s. to 41s., and hematite pig at 42s. to 44s. There is a steady business being done in bars at £4. 17s. 6d. per ton; the best quality, however, is being sold at £5. 10s. Hoops are going at about £5, and plates at £7 and upwards. Both crucible and Bessemer steel continue to be in good demand, and several large orders for the former kind have been placed recently. Most of the Sheffield converters are busy, and there is some talk, at least in one firm, of putting down new plant. Not only has the export trade been more satisfactory during the past few weeks, but the home markets have also been better customers. Manufacturers and merchants are doing a large business with Germany, France, Russia, and Austria; and some are developing a connection with Spain with specialties in competition with America. There is comparatively little being done in armour plates and gun forgings; projectiles are in good demand, however, and Firth's and Hadfield's are busy in this department. Shipbuilding and railway materials find steadily extending markets. Marine engines and propellers, and rails, tyres, axles, and springs are on large order. Hydraulic and other machinery is yielding fairly abundant work in the engineering shops; and at the rolling mills operations are more constant. For colliery plant there is an encouraging inquiry. The commercial event of the week has been the issue of Messrs. John Brown & Co.'s report. The profit on the year's trading is £45,539, which, with the balance of £20,950 from last year, makes a total balance of £66,489. Still the dividend is only 5 per cent., as against over 6 per cent. for the past four years. Edge tools are selling well in the home markets, on the Continent, and especially in the Colonies. The best descriptions of cutlery are being exported in large quantities; and table cutlery, chiefly in cases or cabinets, is just now being very freely ordered.

NORTH STAFFORDSHIRE, 20th June, 1888.

The Iron Trade.—Towards the close of the quarter there is a somewhat better feeling in the iron trade, and in some instances makers are holding out for a small advance on the lowest prices which have recently prevailed. All idea of any real improvement before the autumn, however, has vanished, and producers are not very hopeful with regard to the early prospects of 1888 being realised at all. In spite of its speculative character the dulness of the Scotch pig iron market has some influence here. The price of No. 1 foundry iron is about 40s., and of forge iron from 34s. to 35s. into truck.

North Staffordshire Mining Institute.—At the meeting of the Institute held last week, Mr. A. R. Sawyer, Assistant Inspector of Mines, read a paper, illustrated by diagrams, on some "Experiments with regard to the holding power of glands on wire conductors under varied conditions." After describing different methods of securing wire conductors in the shaft and maintaining them there in a constantly rigid state, Mr. Sawyer urged the importance of great care being taken in screwing up the glands, and pointed out that the safety of underground workers in pits where conductors were used was at least twice a day dependent upon their efficiency. Attention has frequently been called in these columns to the efficient and beneficial work which is being done by the Institute in connection with the mining interests of this district; this success of the Institute is due in no small measure to the willingness of Mr. Sawyer to give the members the benefit of his wide experience, and the above lecture will form an important addition to the literature of mining which the author has already published.

LEICESTER, 20th June, 1888.

Wool Spinning and Yarn Trades.—The wool market is extremely quiet at present, and all operations, except small sales for pressing wants, are suspended. There are two reasons which clearly account for this quiescence: the London wool sales commence to-day, and their tendency will largely affect the rates in the market here; also, the local wool fair will be held at the close of the current month, and will settle the price of the raw material for some little time to come. The complete absence of speculative dealing is good for the market, as the true state of affairs is more clearly indicated and quotations are more reliable. The present condition of the wool trade may be said to be a waiting one. Spinners are not very well employed, and many of the workpeople are on short time, more especially those employed on worsted yarns. Orders are offered in these yarns, but the prices quoted make spinners chary of accepting them. In lambswools there is rather more being done, as the prices have not fallen so low in this department. In fine yarns the best trade is being done, and prices are firm, with an upward tendency. Yarn merchants are doing an unequal trade, and the volume of it is not very great.

Hosiery Trade.—In the lighter goods an improved demand is apparent. Some fairly good orders have been placed for the autumn delivery of heavy goods, but the trade as a whole is not so satisfactory as could be wished.

Boot and Shoe Trade.—The trade at present is in its usual state, but the turnover of the year so far is much below the average. Most of the factories are now fully employed. Home orders are for encouraging amounts, and the shipping trade to the Colonies is brisk. Several of the leading houses are sending excellent selections of goods to the Melbourne Exhibition. The financial state of this industry is now sounder than for some time past; failures lately have been very infrequent and only for small amounts, and there is an absence of rumours of monetary weakness. Leather merchants are doing a quiet but steady business; the rates rule extremely low, and the market does not indicate any immediate prospect of recovering a firm tone.

BARROW-IN-FURNESS, 20th June, 1888.

The Labour Market.—The circulation of reports that a revival was being brought about in many of the industries of Barrow is having the effect of drawing to Barrow a large number of skilled and unskilled workmen, as well as several tradesmen for whom at the moment there is nothing to do. There is no reason to doubt that in the course of a short time there will be room for many workmen in the shipbuilding, engineering, and other trades; but at the moment there is not more work in the town than will employ those who are living there, while the complaint is frequently urged that there are too many shopkeepers in the place.

Iron and Steel.—A better tone is reported in the hematite pig iron trade. The demand is stronger from all sources, and more iron is required as well for prompt as for forward delivery. The output has not been increased, as there is no need for this with the large stocks in hand; but stocks have been very sensibly reduced, and it is noteworthy that the tendency is in the direction of a still further reduction, as not only are home buyers taking large parcels, but considerable shipments are being made to the Continent and elsewhere. Prices are quoted this week at 43s. per ton net f.o.b. for mixed parcels of Bessemer iron, and 42s. for No. 3 forge and foundry iron net f.o.b. In the steel trade a great improvement is noticeable. There has been no diminution in the activity at local steel works, but the market lately has been much weaker in tone, and makers who some time ago were well sold forward, had cleared out a large number of orders. There is now, however, a very good inquiry for steel rails, and for shipbuilding material, both of which departments are very briskly employed. There is not much change to note in the value of steel rails, which remain steady at £3. 17s. per ton for heavy sections net f.o.b., and £4 to £4. 5s. for light sections. In ship plates the demand has been considerably improved on both local and general account, and prices are £6. 7s. 6d. for plates and £5. 12s. 6d. for angles net f.o.b. The trade in blooms is limited, but there is a fair inquiry on American account at £3. 13s. 6d. per ton net f.o.b. The business doing in billets is steady, and prices are firm at £3. 16s. per ton. Spiegeleisen is in large consumption, and is not only imported in large parcels, but one or two furnaces in the district are producing this metal, which is quoted to-day at £3. 18s. 9d. per ton net f.o.b. In the shipbuilding trade there is a gradual industrial revival, and as the recently accepted orders for large ocean steamers are to be supplemented by others of equal importance, there is reason to look forward to a very brisk business in these departments. Iron ore is in good demand, and prices have advanced. Ordinary qualities are now quoted at 9s. 6d. to 12s. per ton net at the mines.

MIDDLESBROUGH, 20th June, 1888.

Pig Iron.—The tone of the market still continues to be firm, although business is very quiet. There is an increasing confidence in a steady, though perhaps slow, advance. There are buyers at 31s. 6d. per ton for prompt delivery, and 31s. 9d. for the third quarter. Makers have advanced their price to 32s. Warrants are 31s. 4d. per ton cash for Connal's No. 3 G.M.B., and 42s. 6d. for Connal's Nos. 1, 2, and 3 hematite, nominally. The stock in Connal's store is still decreasing. The amount on Saturday was 284,480 tons.

Shipments of Pig Iron.—The shipments of pig iron are not much more than half of what they were during May, but they are ahead of what they were during June, 1887. During the first eighteen days of June this year they amounted to 44,197 tons, as against 42,221 tons in the corresponding period of last year. There is about a third less going to Scotland, but nearly double the quantity to Germany and Holland and other foreign countries.

Manufactured Iron and Steel.—There is no change in these departments of trade. The mills are working steadily on regular time. Finished iron is of course more precarious, but as yet new orders have succeeded the old in sufficient quantity to keep the works going. The strike in the ship yards at no time affected the deliveries, and the satisfactory settlement has taken away even the possibility of such a circumstance.

Shipbuilding.—The men having gone in at last upon the masters' terms, the yards are once more in full work. The terms are 5 per cent. advance on piece work, and 1s. 6d. per week advance in time wages, to date from the first week in July. The North Shore ship yard in Stockton, which has been shut up for some time now, is to be opened shortly. Altogether the shipbuilding industry is in a favourable condition.

Salt.—The demand for this article still continues, and all that can be manufactured is at once disposed of. A considerable quantity is used by the fish curers, who have begun operations for the season.

NEWCASTLE, 20th June, 1888.

Chemicals.—This being "race week" industrial operations are temporarily suspended throughout the district, the only exceptions to this rule being certain departments of the chemical factories, in which a stoppage would involve exceptional loss and inconvenience. Soda crystals, bleaching powder, and high strength caustic are the products principally in demand, and the works engaged in the manufacture of these commodities are generally well employed.

Copper.—The establishments of the Tharsis Copper Company at Hebburn and Howdon are kept in steady work, though some inconvenience has been caused by a wages dispute with the operatives in one of the departments. The shipments of "purple ore," and briquettes manufactured therefrom, to local steel works, and also to America, have been very satisfactory of late, and this now forms a most important branch of the company's operations.

Lead.—The manufacture of sheet lead is just now pretty brisk, the requirements for building purposes being somewhat large. The production of white and red leads is quite up to the average, and on the whole the industry may be said to be in a fairly healthy state.

Cement.—The whole of the cement works in the district are now very busy. The local demand has increased, and shipments to America have been unusually heavy lately; a diminution of stocks has therefore taken place.

Paints, &c.—The manufacturers of paints, compositions for ship bottoms, patent lubricants, &c., are generally doing a brisk business, and the production in each of the branches named is much above the average at this time of the year. The Mica Lubricant Company, South Shields, besides having a very large home demand for their specialty, are fulfilling some very heavy foreign orders just now.

The Timber Trade.—Up to the present time the arrivals of timber cargoes at the port have been few as compared with former years, and there is consequently little animation in the trade. With the advent of July, however, it is expected that the imports will increase very largely.

The Coal Trade.—For steam and manufacturing coals the demand keeps good; but as is usual at this time of the year, there is very little inquiry for gas and household qualities. The shipments of coal and coke from Tyne Dock for the week ending June 16th were 100,641 tons, a decrease of 8275 tons as compared with the corresponding week of 1887.

The Shipbuilding Trade Wages Disputes.—At a conference of employers and workmen's representatives, held at Newcastle on Monday, an arrangement was arrived at which will prevent an interruption of work. Under this arrangement the members of the Boiler Makers' and Iron Shipbuilders' Society, who demanded an immediate advance of 10 per cent. all round, will receive an advance of 5 per cent. on the 1st August, and the members of the Amalgamated Joiners' Society, who asked an advance of 3s. per week, will get an immediate advance of 1s., to be increased to 1s. 6d. on 1st August.

DUNDEE, 20th June, 1888.

Linen and Jute Trades.—In both branches of the local trade business during the past fortnight has been fairly active, and the demand fully maintained. Holders are anticipating a higher range of prices and consequently are not eager to sell, and spinners being in the meantime well supplied are not disposed to operate at an advance. The contract market continues strong. The Russian exchange remains high, and shippers are firm in their demands. There is a good demand for both flax and tow yarns, and the tendency is against buyers. Manufacturers hold out against the advance on the ground that the prices obtained for cloth are still unremunerative. There is, however, a better demand for linens both on home and on American account. In Fife, manufacturers are reported to be busy with orders on their books sufficient to keep all their looms going. Heavy goods, including sailcloth, are selling more freely. A good business is passing in raw jute at full rates. The new crop sells freely, and prices are rising. Calcutta telegrams report the market there as steady, with an upward tendency. Advices from the growing districts represent the prospects of the new crop to be good. Jute yarns are in active demand, and rather higher rates are obtainable, more especially for immediate delivery. In jute fabrics good orders for Hessians have recently been placed, and some of the larger makers, being well sold forward, are holding for higher prices. Sacking and bagging sell freely at firm prices. The narrower widths of tarpaulin are in less request.

Improvement in Weaving Machinery.—A new checking motion for weaving, for which several important advantages are claimed, has been patented by Mr. John Allan, engineers, Lyon-street. It is stated that by means of the new machine a greater number of shots can be inserted in a pattern than by any machine previously in use, and that the change of shots can be accomplished with greater facility, while the weight of the machinery which effects this is much less than in the present machines for two and three shots. In Mr. Allan's patent, six shuttles are at work from each end of the loom, and by an ingenious arrangement the number of shots can be regulated to suit the pattern.

THE EASTERN ARSENAL OF TIENTSIN.

By Allan C. Wylie.

I.

After crossing in a flat bottomed boat to the east side of the river Peiho, and passing large numbers of Chinese coolies busily employed on the earth works of the new railway, and after a ride of three miles across a plain interspersed with mounds indicating the last resting places of generations of Chinese, the former inhabitants of this district, I arrived at a castellated brick archway leading into the Eastern Arsenal of Tientsin, which is encompassed by a massive wall of earth work about 15ft. high, and this again is surrounded by a moat, almost like a lake, 60ft. to 70ft. wide. The smoke from about twenty large chimneys indicated the existence of a series of factories, and reminded me of a visit to one of the busy manufacturing villages in Lancashire. On passing the archway, I found myself in a large enclosure of fifty or sixty acres, and in this space has been erected from time to time during the last twenty years the various departments which I shall now endeavour to describe. In this area a tramway has been laid down of 30in. gauge, with the necessary turntables and trucks, by which materials can be easily transported to and from the various departments as required. A creek branches off from the Peiho, passing through the southern wall of the Arsenal into a small dock facing the machine shops, by which means all raw and finished materials are at present conveyed to and from the Arsenal. The northern end of this creek also runs into a canal connecting the Peiho with the Pei-t'ang River, which empties itself into the Gulf of Pechili, about eight miles to the north of Taku, at the mouth of the Peiho. By this means the manufactured war materials are conveyed to the various magazines and depôts for distribution to the camps and forts in the provinces served by this Arsenal; but a branch of the new railway will be constructed which will dispense with much of this slow water carriage. In the small dock or basin already mentioned, I saw a light draught stern wheel paddle steamer, 75ft. long by 14ft. beam, fitted with a pair of compound horizontal engines of 20 n.h.p., which is used for conveying officials to and from Taku, Pao-ting-fu, Tunchow, and other places, where a light draught steamer can only be used. I will now give a brief description of the various shops:—

Pattern Shop.—This consists of three rooms, in which are made the wooden models of machine castings for the foundry, and is fitted with a general joiner, and several wood turning lathes. The finished models I examined were of very excellent workmanship, and contrasted favourably with what I have been accustomed to see turned out at home.

Moulding Shop.—This building is about 120ft. long by 50ft. wide, with a roof of more than the average height. It is fitted with two 5-ton hand cranes, arranged to meet at a centre over a large tank, so as unitedly to lift a 10-ton casting. Two 3-ton, one 4-ton, and one 5-ton cupolas of the ordinary description furnish the metal required. In this shop all kinds of castings in loam, and dry and green sand, are made; also chilled rolls for rolling copper, and shells for various sizes of guns. These shells are formed in moulding machines designed and made in the Arsenal. The castings produced are very good, and will bear comparison with the average castings from European foundries.

Turning and Fitting Shops.—This department is about 270ft. long by 45ft. wide, and well supplied with a plant of lathes, planing, shaping, boring, drilling, slotting, emery grinding, and other machines by our best English makers. The whole are driven by a 30 n.h.p. horizontal condensing engine.

Boiler Shop.—The boilers, tanks, torpedo mines, and other work are made in this building, which is very roomy, and well arranged with an excellent plant of powerful punching, shearing, plate bending, drilling, and other machines, including a very good design of boiler shell drilling machine; also a superior plant of Tweddell's hydraulic portable and stationary riveting and flanging machines, with the necessary pumps and accumulator. The work done here will also bear the closest inspection.

Smiths' Shop.—This contains eleven fires, driven by fan blast, and fitted with a 20cwt. steam hammer, the only one in the Arsenal.

Rolling Mills.—This department comprises a melting shop for casting brass and copper ingots, from whence they are taken to the annealing ovens, and then passed through a series of rolls until reduced to the required thickness. In this shop there is also a well arranged roll lathe, with traversing emery wheel for re-grinding the chilled rolls. The whole is driven by a horizontal condensing engine of 30 n.h.p. This plant has been made by the old established firm of James Watt & Co., Soho, Birmingham.

Cartridge Factory.—This large building contains a plant of machinery for the manufacture of cartridges and percussion caps, consisting of a complete set of punching, drawing, and finishing machines, producing 10,000 cartridges per day. Also machines for making percussion caps for the old fashioned rifles still in use; a hydraulic press and plant for making lead rods for bullets, and several bullet forming machines. The cartridge filling and finishing shops are detached from the factory, but near to it; a series of buildings at a safe distance being used for the manufacture of the various kinds of detonating compositions required. The whole of this machinery was made by Messrs. Greenwood & Batley, Leeds, and is driven by a high pressure horizontal engine of 15 n.h.p.

"Cash" Foundry.—In this department, which is not generally to be seen connected with arsenals, a large number of men are busily engaged in moulding, casting, and finishing the "cash" used as coin all over China—Mexican dollars and Sycee silver being used in large transactions. I may state here that I saw these dollars made by screw presses worked by hand in the mint at San Luis, Potosi, Mexico, in 1884, and also in the mint at Zacatecas, by a plant of new machinery sent out by Messrs. James Watt and Co. The cash are made from an alloy of copper and zinc, nearly the same as the well known Muntz metal; and it takes about 5000 of them to answer as change for a sovereign, so minute and low do prices run to in this country, of which I will only give one instance. The fare for crossing the ferry on the Peiho was only two cash, or less than half a farthing. This cash foundry will shortly be superseded by a new mint, nearly completed; the machinery of which is now being erected. It will comprise two blank cutting machines, ten coining presses, and all the die sinking and other machines complete; and will be driven by a horizontal tandem compound condensing engine, with cylinders 10in. and 17½in. diam., and 20in stroke. This engine is one of the best of the type I have seen, both as regards design and workmanship, and reflects great credit on the makers, Messrs. Greenwood & Batley, Leeds, who have supplied the whole of the plant for this mint.

Fuse Department.—This building is well laid out with lathes, copying machines, &c., for the manufacture of the various kinds of fuses required for the guns of the army and navy.

Torpedo Department.—In this building are manufactured the electrical fuses, torpedo cables, and batteries. The wires for the cables is drawn on the native system, the draw plates being of Chinese manufacture of a very hard description of cast iron, which seems to answer the purpose admirably. There are also several braiding machines, and machines for covering the wire with guttapercha.

Gun Cotton Factory.—The manufacture of this article is carried on in a large block of buildings, consisting of: (1) A cotton cleaning room, in which the material, which is all grown in the neighbourhood, and of very short staple, is cleaned by one scutching and one carding machine. (2) A room containing the dipping troughs and cooling tanks, also the acid measuring and mixing tanks. (3) A room containing one hydro-extractor for extracting the surplus acid before the first washing. (4) A room containing two large washing tanks made of wood, in which the material is immersed after leaving the hydro-extractor, and stirred for some time in cold water by manual labour. (5) A room containing another hydro-extractor, through which the gun cotton is again passed, and then boiled by steam in wooden tanks lined with lead. (6) A room containing a pulping machine, similar to the beating machines in our paper mills; from this machine the pulp is conveyed to a service tank, and drawn off as required. (7) A room containing two hydraulic presses and pumps, communicating with the service tanks in room No. 6. The smallest press converts the pulp into various shaped discs as required, and the large press reduces these discs to about a third of their previous thickness; in the same room is also a neat little double spindled vertical drilling machine for boring the holes in the discs for detonators. (8) A room for steam drying the detonating discs, which completes the process, from which they are conveyed to magazines several miles distant until wanted.

Sulphuric Acid Works.—This acid is made in a building containing a large lead lined chamber, capable of producing about 15cwt. of acid daily, with the necessary platinum stills for concentrating the same.

Nitric Acid Works.—Adjoining the above works is a building in which is erected the necessary retorts and condensing apparatus for producing the nitric acid required for the manufacture of gun cotton.

Powder Mills.—These mills were begun about eighteen years ago, and have been increased from time to time. They now comprise: (1) A charcoal burning house with six retorts. (2) A charcoal grinding mill, nearly similar to a large coffee mill, fitted with a horizontal reel, covered with wire cloth of very fine mesh, for sifting the ground charcoal. (3) A sulphur refining house, the plant in which consists of two refining pots in the form of stills, fired in the ordinary way, the lighter portions, containing sulphurous acid and a small portion of sulphur, passing into a dome, where it is condensed—the heavier fumes afterwards passing through a water jacketed pipe, at the end of which a receiver collects the liquid sulphur, from which it is ladled out into wooden tubs, and conveyed to the grinding mill when cool. (4) A sulphur mill, in which the refined sulphur is ground to a fine powder under a pair of heavy rolls, constructed on the mortar mill principle. (5) A nitre refinery, consisting of one large copper boiler, in which the crude nitre is boiled, and then passed through straining cloths into four coolers, where it is agitated with wooden rakes while cooling; it is then passed into troughs and washed with distilled water until free of salt; the nitre seemed of excellent quality, and an abundant supply of the raw material is obtained from the neighbouring province of Shansi. (6) A mixing house, where the various ingredients are weighed and passed through a small mixing machine in charges of 50lb. (7) The incorporating mills, and in the above charges are first conveyed to a small magazine, and from thence brought as required to the incorporating mills, four in number, comprising twenty pairs of edge runners, driven by four compound condensing beam engines, each of 20 n.h.p. (8) A press house, in which the material from the incorporating mills is pressed into cakes by hydraulic presses, containing alternate layers of powder between copper plates. (9) A corning house, where the powder is passed through corning rolls, and separated into the different sized grains required. (10) A glazing and dusting house, the plant in which consists of four glazing barrels, and the necessary dusting and separating machines. (11) A drying house, where the powder is put on wooden trays with canvas bottoms, and placed on racks over steam heated pipes, giving off just sufficient heat to slowly remove all remaining moisture; the finished powder is then conveyed to the packing house, and from thence removed to the magazines daily. The whole of the machinery, engines, boilers, and other apparatus in these mills have been made by Messrs. J. and E. Hall, Dartford, Kent, and the design, workmanship, and general arrangement are very satisfactory.

SERIOUS COLLISION DURING A TRIAL TRIP ON THE CLYDE.

On Saturday last, a collision, involving the death of three persons and more or less serious injury to some twenty others, took place on the "measured mile" off Skelmorlie, near Wemyss Bay, on the Firth of Clyde. The "measured mile," as is well known, is the distance marked at either extremity by posts on the shore, by which steamers effect their speed trials. On the forenoon of Saturday, two vessels proceeded to the point off Skelmorlie for the purpose of being tried. These were the "Balmoral Castle" and the "Princess of Wales." The "Princess of Wales" was a new paddle steamer recently built by Messrs. Barclay, Curle, & Co., Whiteinch, for the Southampton and Isle of Wight Steam Packet Company. The "Balmoral Castle" is a vessel whose name was at one time familiar enough. A screw steamer of about 4000 tons, she was formerly in the Castle fleet of Messrs. Donald Currie & Co., and was subsequently bought by a Spanish company, and while in their hands was the scene of a great fire, in which some two hundred persons lost their lives. Recently, the "Balmoral Castle" has been thoroughly overhauled and re-fitted by Messrs. McMillan & Son, Dumbarton. Until the evidence comes out in an authoritative fashion at the inquiry, it is difficult to state precisely how the accident occurred; but the following appear to be the facts: The "Princess of Wales" had completed one run on the "measured mile," and was about to run back, when the "Balmoral Castle" was sighted 150 yards distant. Through some misunderstanding, which will doubtless be brought out in the evidence, the "Princess of Wales" either crossed the bows of the "Balmoral Castle," or the "Balmoral Castle" attempted to cross the bows of the "Princess of Wales." The collision occurred almost immediately the possibility of danger was apprehended. The extremely short interval which elapsed, however, sufficed for Mr. James Gilchrist, jun., of Messrs. Barclay, Curle, & Co., who had charge of the engines, and who was on deck at the time, to run into the engine room and turn the engines to full speed. Had this not been done, the vessel would have been struck and cleft through at the engine space, thus probably involving explosion of the boilers and immediate submergence. As it was, the "Princess of Wales" was struck abaft the engine room bulkhead, and was cut completely in two. The after part of the vessel sank almost immediately. An attempt was made to tow the forward half of the "Princess of Wales" to the beach, but before this could be effected the bulkhead appeared to give way, and the vessel settled down in deep water almost at once. The "Balmoral Castle" was considerably damaged on the port bow, and is now under repair. It is expected that an attempt will be made at once to raise both parts of the sunken vessel. Messrs. Ross & Marshall, Greenock, have been instructed to conduct the operations.

FRIDAY, 22ND JUNE, 1888.

STEAM BOILER LEGISLATION.

BY the withdrawal of Mr. Provand's Boiler Inspection Bill, on the 5th inst., the last has probably been heard for this session of any attempt to legislate either in the direction of the examination and certification of boiler and engine attendants, or of the compulsory inspection of steam boilers. Lord Stanley's Bill for the Registry and Inspection of Steam Boilers, read a second time in the House of Lords on the 15th August, 1887, was allowed to drop when he severed his connection with the Board of Trade; and the Bill entitled the Steam Engines and Boilers Bill for the examination and certification of attendants was rejected on the 17th April, in the House of Commons, on a division for the second reading, by a considerable majority, the general opinion being that nothing had been brought forward by the supporters to justify the members in thinking that such a measure would be likely to produce the results the promoters anticipated. Although no parliamentary action has been taken with regard to the Boiler Registry and Inspection Bill, yet much information has been given, and considerable discussion of its conditions has taken place, not only in our own columns, but in the general Press, during the interval. In our issue of the 17th February last, we drew attention to this Bill, and gave a summary of its leading provisions; at the same time we put the following questions: What do we really require? and is further legislation the best means of obtaining it? Since that time one of the Assistant Secretaries of the Board of Trade has presented some data for the consideration of the Right Hon. The President of the Board of Trade, which has been presented to both Houses of Parliament, and issued to the public, for the apparent purpose of proving how great the need is for legislation; or, to use the writer's own words, "to meet what is believed to be a great and growing evil." The information and data supplied do not appear, however, to establish the conclusion he would seem to desire. A large portion of this "Memoranda" is devoted to a consideration of the working of the Boiler Explosions Act, 1882, and in pointing out what appears to the Assistant Secretary to be its imperfections. A consideration of some of the statements made will enable the reader to understand in some degree the singular inaction of the Board of Trade during the time this Act has been in operation, and will explain the grounds upon which it has practically been allowed, so far as its punitive character is concerned, to be a dead letter. The Assistant Secretary says: "It has been suggested that formal investigations should be frequently held, if for no other reason than to find the owner of the boiler liable in the costs and expenses; but this view is untenable, as being inconsistent with the objects of the existing Act. That object is inquiry, and not punishment." If the Executive of the Board of Trade have all along held these views their inaction is conceivable, but it does not explain either the grounds for arriving at such a conclusion in the face of the apparently quite clear and definite instructions of the Act, nor why the Board of Trade should first seek powers to severely fine peccant boiler owners, and then quietly stultify them and be content with a mere "inquiry."

The words of the Act show that "the Court may order the cost and expenses of a preliminary inquiry or formal investigation, or any part thereof, including therein the remuneration of persons holding such inquiry or investigation, to be paid by any person summoned before it, or by the Board of Trade; and such order shall, on the application of any party entitled to the benefit of the same, be enforced by any court of summary jurisdiction, as if such costs and expenses were a penalty imposed by such Court." Apparently nothing could be clearer or more definite, and it is important that the reasons should be given, why—to quote from the same authority—"there is no power to make an owner or user, however careless or culpable he may have been, pay the expenses." The Board of Trade have power to make formal investigations "either upon or without preliminary inquiry," and where culpability is found and proved, so far as the ordinary construction of language goes, it would appear they have power to charge expenses. It is beyond doubt that so far as the public are concerned, that has been the impression, and there can be little doubt that the fear of publicity and of such costs being laid upon boiler owners has been the cause of a great number of boilers being placed under insurance, and of the large and satisfactory reduction in the number of explosions. It is stated in the "Memoranda" that 446 explosions, 489 deaths, and 707 cases of personal injury have occurred during the last ten years. But during four or five years of this time the particulars could only be gained from newspaper reports and unofficial sources; and very many explosions, or at least mishaps such as are now entered as "explosions," escaped record. In the fifth annual report upon the working of the Boiler Explosions Act, 1882, the same authority states that 37 explosions took place, with 24 deaths, and 44 injured; and these figures show a considerable reduction in the rate of explosion, the death rate, and number injured. A consideration of these and similar facts would tend to show that what we want as an immediate requirement is that the Boiler Explosions Act, 1882, should be amended—if it be correct, as stated, that no power at present exists to enforce costs even in cases of formal investigations—and that unmistakable powers be given, so that in every case where culpability can be clearly proved, the punitive section of the Act may be put in force. An examination of the number of explosions occurring in France, Germany, and other countries where governmental inspection is enforced, goes to show that the rate of explosions in this country is already less than that prevailing abroad under the closest governmental supervision; and it may be hoped that the increased attention to boiler engineering, examination, and attendance which has characterised the last six years, will soon reduce the number of explosions to those which are purely accidental, or against which inspection would have been ineffectual. It seems remarkable, if no power exists to assess costs, that the public have been so long left in ignorance of such an important defect in the Act, and that no allusion was made to the matter prior to the attempted passing of the Boiler Registry and Inspection Bill. It is very desirable that the matter should now receive the earliest possible attention, and it would form an interesting and valuable subject for interpellation by any member of the House interested in the steam using community.

In the fifth report of the Assistant Secretary upon the working of the Act, to which we have already referred, it is stated that of the thirty-seven cases

Digitized by Google

of explosion which occurred during the year 1886-87, "five cases only were under the inspection of boiler insurance companies. In only three of the cases insured, however, were the explosions attributed to defects which a more thorough inspection on the part of the insuring companies' officers would have revealed. The work of these companies is no doubt often performed under considerable difficulties, arising not only from the unwillingness of some steam users to incur the loss of time and outlay necessary for repairs, but also from the lack of sufficient opportunities for making thorough inspections; but the figures referred to would seem to show that, notwithstanding these drawbacks, the examinations made under the direction of the companies during the year have, in the main, been conducted upon a satisfactory system." Bearing this statement in mind, and having regard to the increased care and responsibility felt by the steam user, under a wholesome fear of the expense of a formal investigation in the event of an explosion being decided as resulting from the want of necessary precautions upon his part, it would appear that what is immediately required is a wise and judicious use of our present legislative machinery, amended if necessary to make its working more clear and decisive.

Before concluding, we may remark that the value of the evidence provided by the "Memoranda" to which we have referred depends altogether upon its accuracy, and it is of the utmost importance that the Assistant Secretary should carefully sift the statements that are made to him; otherwise he may be led into errors which will render his conclusions valueless. Thus in quoting the evidence given by the late Sir William Fairbairn before the Mr. Hick's Committee on Boiler Explosions held in 1871, the Assistant Secretary would only appear to have taken those parts which are apparently detrimental to the boiler insurance system, and which tend to throw discredit on the operations of what the Assistant Secretary calls "the then existing *quasi* inspection societies," but forgetting it would seem that Sir W. Fairbairn was at the time the chairman of one of such societies. From all the sources of information that are available, it seems clear that public interest in the question of boiler legislation is extremely weak, and that whatever vitality it may have, and all such steps as have up to the present been made, are due to long sustained efforts on the part of a few persons, whose advocacy is marked by perhaps a very natural bias towards their own schemes. While regard for the public safety should always be a paramount consideration in dealing with this matter, still the steam using community should certainly see that their industrial activity is not hampered by any ill-advised legislation or red-taped officialism.

TEXTILE STATISTICS.

I.

THE "German Archive of Commerce," published by the Home Office of the German Empire, recently gave a very able and exhaustive essay on the "Wool Industries of Great Britain." This treatise is divided into two parts, one of which reviews the statistical, and the other the economical aspect of the case. The following summary taken from the latter part may be of special interest to the Bradford trade.

At first the period of depression is dealt with which was experienced by our textile industries in 1875, manifesting itself in a continued preponderance of supply over demand. The Royal Commission on the Depression of Trade, in its report, stated that the principal cause of this depression was that the Franco-German War suddenly opened enormous fields of trade, which, after the conclusion of the war, gradually closed up again, whilst the increased production in the United Kingdom continued. However, although at present this over-production seems to have found its level, there are complaints from all sides that the profits have materially decreased, and are often turned into actual loss. To speak of the decay of British wool industries would be a fallacy, from the simple reason that, according to unmistakable evidence, the extent as well as the volume of production has, generally speaking, increased. On the other hand, however, the average value of the goods produced by the British wool industries, as well as the profits which the capital employed therein yielded, has decreased. The present condition therefore is aptly designated with the description of depression of prices and diminution of profits. Most of the countries competing with England in the world's markets, and especially the greater part of the British Colonies, gradually adopted the policy of protective duties, and this could not remain without effect on the industries of the United Kingdom; whilst in other countries the industries gained strength, and the consumption of raw material sensibly increased. A rise in the importations of foreign manufactured goods into the United Kingdom may be noticed. Thus the import of woollen yarn amounted to 10,803,000lb., representing a value of £1,362,700, in 1881; and 15,924,000lb., representing a value of £1,999,100, in 1885. The import in woollen stuffs was computed to be, in 1881, £5,985,863 value; in 1885, £7,374,808 value. We find therefore, on comparing 1885 with 1881, that there has been an increase of import of woollen yarns into the United Kingdom of 47·4 per cent. in quantity, and of 46·7 per cent. in value, and an increase of wool stuffs of 23·2 per cent. in value. For the last fifteen years this increase is computed to be about 25 per cent. The export of British woollen yarns amounted, in 1881, to 29,731,400lb., representing a value of £4,382,898; and the export of wool stuffs amounted, in 1881, to about 272,874,900 yards, representing a value of £18,128,756; in 1885, to about 272,983,400 yards, representing a value of £18,847,053. Thus, on comparing 1885 with 1881, there is an increase of the export of British woollen yarn of 46·2 per cent. in quantity, and of 35·8 per cent. in value; whereas the increase in the export of British wool stuffs has only been about 0·05 per cent. in quantity, and 3·9 per cent. in value. For the last fifteen years there has been a decrease in value in the export of British wool stuffs of about 43 per cent. Taking, however, the fall in prices into account, the decrease of export is estimated at only about 11 per cent. Hitherto it was generally assumed in England that the chief cause of the growing imports of foreign manufactures was to be explained by the lower cost of production of other countries. It appears, however, from the report of the Royal Commission, that the main cause of this increase is the influence exerted on the English market by the change of fashions emanating from foreign countries. On the other hand, those British experts who placed the above causes in the foreground, laid stress upon the fact that the industries of foreign countries are in a position, by lower wages and longer hours of labour, to compete successfully with English industries in the British as well as in the so-called neutral markets. They pointed especially to France and Germany, who compete with England in the Colonies; their goods, they maintained, were often better and much more adapted to the taste ruling in the Colonies. The present extension of the British wool industry, and the development which the same experienced in the last thirty years, are demonstrated by the accompanying tables taken from the last report of the Factory Inspection Department of the Home Office.

According to these tables, the number of power looms has increased 23·5 per cent. during the period from 1868 to 1874, and by only 1·57 per cent. from 1874 to 1885. On the other hand, the number of spindles, which in 1868 amounted to 4,190,670, decreased in 1874 to 3,165,569 and in 1885 to 3,054,144. The total number of hands employed in the British wool industries was, in 1874, 134,605; in 1885, 139, 316; consequently, there has been an increase of 3½ per cent. in eleven years. The number of children employed in these industries was lower in 1885 than at any other time since 1856, and the number of hands under eighteen years of age is lower now than between 1868-1874. On the other hand, the number of male hands over eighteen years, and of females over thirteen years, has steadily increased. Of the 1918 factories of the woollen industry at present in existence, there are in in England 1503; Scotland, 274; Ireland, 141.

In the worsted industry accordingly a decrease of 2270 is shown in the number of power looms, and an increase of 2 per cent. in the number of spindles has taken place since 1874. The total number of hands employed in the British worsted industry, according to the above statistics, amounted, in 1874, to 142,097; in 1885, to 138,230; consequently, there is a decrease of 2870 in the last eleven years. The explanation of this decrease lies in the greater efficiency of machinery, and in the fact that in 1885 there was a decrease of 11,516 in the number of children, while 7649 more grown up persons were employed than in 1874 Of the 725 factories of the worsted industry in existence at present, there are in England 697; Scotland, 24; Ireland, 4. In the British wool industries (woollen and worsted) there were employed in 1885 a total of 277,546 hands, against 276,702 hands in 1874. These were distributed in 1885 as follows: England and Wales, 241,183; Scotland, 33,025; Ireland, 3338.

THE EDISON GLOW LAMP PATENTS.

WE brought the report of the case of Edison *v.* Holland down to the end of the eighteenth day in our number of the 25th of May. On the 30th of May, when the Court again sat after the Whitsuntide recess, Mr. Swan's evidence was completed, and the next witness was Mr. Charles Henry Stearn, the managing director of the Swan United Electric Light Company, whose persevering efforts in obtaining a sufficiently perfect vacuum in incandescent lamps, both before and after the date of Edison's patent, contributed in a very large measure to the eventual success of incandescent lighting. Mr. Stearn was called on behalf of the plaintiffs and examined by the Attorney-General. He corroborated Mr. Swan in his statements that the early lamps made by Mr. Swan were all of the paper and stick carbon character, and that the first thread lamps which were exhausted by Mr. Stearn were exhibited by him in his house at Rock Ferry, somewhere about June or July in 1880, and not in 1879, as suggested by the defendant's evidence. Mr. Stearn said he had had no cotton thread lamps given to him by Mr Swan before March, 1880. Mr. Stearn was cross-examined by Mr. Finlay at some length as to an article by Mr. Stearn, published in Germany in 1885, in which he had reviewed the early steps in incandescent lighting made by different inventors. In that article Mr. Stearn had stated that prior to the date of Edison's patent all the essential principles of electric lighting were

Digitized by Google

known, and he now adhered to that statement, and further, that all that remained to be done at that date was to perfect the details for putting those principles into practice. Mr. Stearn explained that Edison's English patent contained four claims, but the German Patent Office had rejected the second one—which is the one to which almost the whole of the evidence given in this case has been directed—and Mr. Stearn added that it was the most important part of the patent, and that no practical success attended Mr. Edison's early lamp. He had never known of a lamp made strictly according to Edison's specification being sold. The conclusion of Mr. Stearn's paper was to the effect that, although much credit was due to Edison, his scientific results did not precede, either in invention or merit, those of Swan and other inventors whom he enumerated. One or two unimportant witnesses were called, and then Mr. Imray was re-called, and stated that he had succeeded in carbonising in sand in a coke furnace, and that he had carbonised various fibres in an iron vessel without either sand or plumbago packing. In this case he had used a gas furnace. In cross examination, he admitted that if he had continued the carbonising process for as many hours as the plaintiffs carbonised the filaments in the lamps they sell, they would probably have been burnt; and it appeared that the iron box had been repeatedly used in some carbonising process before Mr. Imray used it, and that it had a certain amount of graphite on the inside walls when he used it.

Mr. Charles Henry Gimingham, the resident superintendent at the works of the plaintiffs, was the next witness. He produced a large number of lamps, most of which had been recently made at the plaintiffs' works by his brother, for the purpose of showing that the directions in Edison's specification were sufficient. He had the lamps tested for duration at the rate of 10 watts per candle. On cross-examination, Mr. Gimingham stated that he had on one occasion, immediately after hearing Sir Frederick Bramwell's evidence, tried whether he could carbonise in one of the ordinary crucibles used by the plaintiffs in their ordinary carbonising furnaces, and had found that the filaments were burnt. He had not repeated the experiment. Mr. Glazebrook, of the Cavendish Laboratory, Cambridge, was next called to speak to Despretz's experiments, and that brought the evidence in the case to a close.

Mr. Justice Kay intimated in the course of the proceedings that there was in this case a very direct conflict of evidence on more than one point in Edison's specification between the eminent scientific gentlemen on both sides, and suggested that each side should perform any experiment of which evidence had been given by that side, in the presence of two of the scientific witnesses on the other side, and in the presence of some eminent man of science to be subsequently agreed upon. This course was adopted. Professor Stokes has been requested to attend and report the results to Mr. Justice Kay.

WEEKLY WAGES BILL.

A Bill has been introduced into the House of Commons, backed by several labour representatives, to provide for weekly payment of wages in Great Britain and Ireland, and enacts that the wages of every workman engaged by time shall be paid in full by the employer to him at least once in each week. In case of a workman being engaged otherwise than by time, the wages earned by him shall be paid to him in full at least fortnightly, or by giving one day's notice to his employer he may require payment of 75 per cent. of his wages weekly. The Bill also requires the provision by an employer of pay notes showing the amount of wages earned to be furnished to any workman requiring the same on the day previous to that on which his wages are payable. The Act applies to labourers, servants in husbandry, journeymen, artificers, handicraftsmen, miners, railway servants, or others engaged in manual labour. Any employer contravening this Act is liable to the penalty imposed by Section 9 of the Truck Act, 1831. We are not aware of any grave objection to the passing of such a measure. Fortnightly payments prevail in some colliery districts—Shropshire for instance—both for day wages and piece work, and if the Bill becomes law an alteration in this system would have to be made. The provision for pay notes would probably be found in practice to be a dead letter as regards miners at all events, as we have been unable to trace any desire on their part for such an innovation. It is somewhat difficult to see what grievance is to be met by the Bill, or what beneficial results would follow its passing into law; and it strikes us as being rather intended to keep the labour party of the House of Commons to the front than to serve the interests of any material section of the community. We would just direct attention to the additional penalty it might involve upon those who are on the threshold of the Bankruptcy Court. On the whole, it would seem to be an attempted addition to that style of "grandmotherly" legislation which is unfortunately now too prevalent.

ANTI-FOULING COMPOSITIONS.

The question of anti-fouling compositions for ships, to prevent the growth of weed, slime, and shells on their bottoms, has occupied the attention of both the Admiralty authorities and those immediately interested in our large shipping companies more or less since the introduction of iron ships. Some six years ago the preservation of the underwater plating of the "Edinburgh" and "Colossus" was specially considered by the Admiralty Board of Construction. A number of compositions were submitted to experiment, two of which were placed on the bottom of the "Mercury," sister ship to the "Iris," and these proved to be, in a measure, somewhat successful. Since then the anti-fouling composition manufactured by Messrs. Kirkaldy & Son, of London, from Captain Renney's patent, has met with considerable support from a large number of shipping companies, it having been found, as the result of its application, that after long voyages ships returned with little or no growth of either grass or shell on their bottoms. Recently attention has been drawn to quite a new composition, manufactured by Messrs. Stevenson and Davies, of Queen Victoria-street, London. This composition was tested by the Admiralty a short time ago, with highly satisfactory results, on the bottom of the "Cossack," and a more severe test of its merits has just been brought to a successful issue. The bottom of the "Sultan" was cleaned and painted in June of last year, and large patches on the port bow and starboard quarter of the ship were covered with Stevenson and Davies' composition. The vessel remained afloat for ten months. On being docked at Portsmouth, it was found that the surface coated by this firm's composition was almost perfectly clean, while the other portions of the vessel were liberally covered with long grass and shells. It would be interesting if the Admiralty were to extend these experiments, and apply this composition to vessels proceeding on distant voyages and cruising in tropical waters. A good anti-fouling composition is invaluable in preventing loss of speed, which results from the increased surface friction of a foul bottom. The speed of a vessel is frequently reduced by a half knot or a knot per hour, and the coal consumption largely increased, by a foul skin. On the score of economy, it is therefore essential that strict attention should be paid to this question, and the best compositions only should be used for the protection and preservation of the bottoms of our costly ships, both in the navy and mercantile marine.

Letters to the Editor.

COAL GETTING MACHINES.

To the Editor of "Industries."

Sir,—With reference to Roberts-Horsfield and Porter's new patent hydraulic coal getter, permit us to correct any wrong impression which might be conveyed by the article in your issue of the 15th inst., under the heading of "Coal Getting Machines," to the effect that the use of this machine as a substitute for explosives "occasions a small increase in the cost of getting coal." On the contrary, the use of our machine will in any case be considerably cheaper than explosives, and as it gets the coal without slack the cost is even further covered by the more marketable condition of the out-put.

Yours, &c.,
Mallett, Porter, & Dowd.

London, N., 20th June, 1888.

FUEL TESTING LABORATORY.

To the Editor of "Industries."

Sir,—I am of opinion that the suggestion put forward by Mr. Bryan Donkin, in the issue of your valuable journal of the 8th inst., is worthy of the attention of steam users and coal consumers throughout the kingdom, and also to no less an extent of the attention of colliery proprietors and coal merchants. Taking the case of a steam user who deals with hundreds of tons of coal per annum, the heat value of the said fuel is a considerable item in his yearly expenses, and as it actually represents the quality of the fuel supplied, a testing station, such as suggested by your correspondent, would not only enable a large consumer to practically value the fuel before purchase, but also enable the vendor to guarantee a qualitative value which would in itself constitute the best advertisement of his business.

A suitable site for such a station would be upon the banks of the Thames, between Plaistow and Purfleet on the Essex bank, or Charlton and Erith on the Kentish shore, where the requisite space may be obtained at a comparatively low rental. The coal may be delivered at a cheap rate of transport upon a suitable jetty, and any nuisance arising from the operation of testing would not, in such a locality, prove to be an objection, while the proximity to London renders it easy of access.

Respecting the first outlay, and assuming that the 20 h.p. boiler and accessories mentioned by Mr. Donkin would suffice for preliminary testing, I think that the certainty of ultimate success would warrant sufficient ground space being acquired in the first instance to allow of considerable addition to the plant at a future time. Allowing, therefore, that £700 would cover the first cost, it does not seem to be a difficult task to raise this sum—say seven persons or firms advancing £100, and guaranteeing £100 per annum each. When we consider the thousand-and-one companies that have been successfully floated during the past two or three years, involving the outlay of an enormous capital, and when the practical and scientific aspect of the objects of such companies is duly estimated, showing but a poor hope of return, it certainly does not seem impracticable to raise a small sum for establishing a concern which is of vital importance to the commercial community, such as that suggested by Mr. Donkin. With regard to the cost of maintenance, we may assume that the services of a competent expert may be retained to attend tests when required at about £350 per annum, and that an assistant and a stoker may be kept regularly; the approximate annual cost may then be placed thus:—

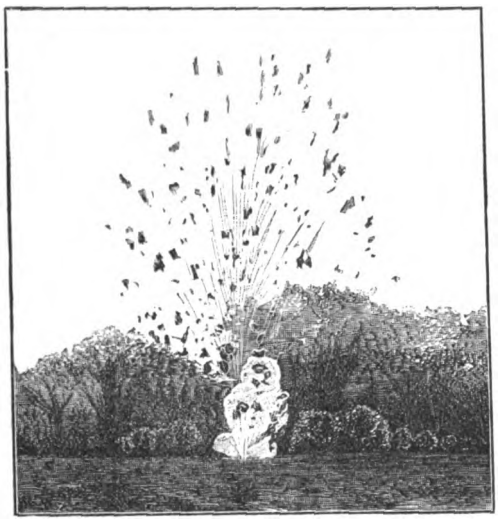
	£
Technical expert	350
Assistant	180
Stoker	65
Rent	35
Stores	16
Depreciation	35
Total	£681

Now, in the City of London and environs there are a vast number of steam users, whose annual expenditure for fuel would render such a testing station an important acquisition, and they, with the merchants who supply them with fuel, would eagerly support the enterprise if it were brought before their notice, and the conditions were reasonable. I would suggest, therefore, that a system of monthly reports of tests should be organised, and that such reports should be sent to subscribers who pay in advance an annual subscription of say 7s. per annum. In this case 3000 subscribers would cover the annual expenses, including postage, salaries, &c., and also pay a dividend of 7 per cent. upon the first outlay and guarantee fund; and such a number may be found to appreciate the value of the system.

The majority of steam users do not care for technicalities; but in this case the appeal to their pockets would command their interest. It is comparatively easy for the quantity of feed water evaporated per diem to be accurately estimated in every factory, and if the monthly reports furnished by the station were detailed in simple language, so that the heat value of the fuel tested could be reckoned in gallons of water evaporated per ton of fuel, every steam user could apply the test for the better regulation of his annual expenses, without going deeply into the technical part of the question of the relative thermal values of different fuels.

Yours, &c.,
Fredk. Walker.

4, Moorfields, London, E.C.,
14th June, 1888.



THE ROBURITE EXPLOSIVE COMPANY, LIMITED.

On Saturday, the 16th inst., we had an opportunity of inspecting the works of the above company at Gathurst, near Wigan, and of witnessing some interesting experiments made with roburite. Roburite is a light yellow powder resembling powdered resin, and has a peculiar smell arising from the benzol used in the manufacture of it. It was invented and perfected by Dr. Carl Roth, of Berlin, whose chief aim was to produce an explosive which might be handled with the utmost safety, and exploded without producing any injurious fumes or explosion of the gaseous mixtures commonly found in mines. The inventor claims that roburite can only be exploded by specially powerful detonators. Should this explosive prove as safe and effective as it is claimed to be, there is no doubt that it will soon be employed in mines and other underground operations, and that its use will tend to greatly reduce the fatal accidents which now so frequently occur. The works of the Roburite Company have been designed and erected by Mr. Hammersly Heenan, M.Inst.C.E., Manchester, and Mr. C. N. Hake, Westminster, London, part of the buildings originally constructed for the Tar Dyes Company being utilised. The works are divided by the river and the canal flowing in the Douglas valley into two portions; the chemical factory being on the south side of the valley, close to the railway connecting Manchester and Southport, while the north side is occupied by the mixing house, the cartridge making, and packing houses, and the several magazines for storing the roburite cartridges and detonators. Both canal and railway afford ample means for transporting the explosive. The chemical factory consists of a laboratory, the benzol shed, and the chlorine shed; while the buildings for the manufacture of nitrate of ammonia are still in course of construction. The valley is spanned by a wrought iron bridge, whereby the two portions are converted into one establishment, thus avoiding many restrictions imposed by the Explosives Act. The north part has been constructed with strict regard to the regulations of the Home Office, though these precautions are hardly necessary with an explosive of the character described. The cartridge making houses are some distance apart from each other, and separated by strong wooden walls, while mounds of earth surround them. The magazines are substantial brick buildings, with double doors, and to each magazine is attached a small ∩-shaped detonator magazine, also built of bricks. One of these magazines is situated close to the canal, to facilitate the carriage by water. All rails passing the mixing house, the cartridge houses, and stores are made of brass, and steel and iron are studiously omitted from all moving parts of the machinery, gun metal being invariably used. The roburite is filled into cylindrical

Digitized by Google

paper bags by hand, with the help of a neat little apparatus. After closing the cartridges, they are provided with a waterproof cover, and are then sent to the packing room, where they are packed in square tin boxes, a number of which are put into wooden cases. A 4oz. cartridge measures about 4½in. in length and 1⅛in. in diam.

The experiments were carried out in an open plot of grass land adjoining the works at the north side, and close to the river. The first experiment was intended to show how unlikely roburite is to explode by rough treatment or heat. A small quantity was placed on an anvil and repeatedly struck with a hammer without exploding it. The explosive was next placed on the fire, then stirred with a red hot iron, and finally a cartridge was blown up with gunpowder without producing any effect. The next four experiments showed the destructive power of the explosive. One, two, three, and four ounces of roburite were simultaneously exploded on a double headed steel rail weighing 90lb. per yard. The 2oz. charge missed fire, but the other three made varying indentations in the rail. Then 2oz. of roburite and 2oz. of dynamite were tried on a similar object, the roburite proving the more effective of the two. Next a 4oz. cartridge was exploded on a similar rail, considerably bending the rail. Finally, 2lb. of roburite were exploded in an earth mine, and made a hole 9ft. square, the peculiar feature being the sharp corners and edges of the hole. We give an illustration of this explosion, which is

Explosion of Earth Mine.

reproduced from an instantaneous photograph taken by us at the time. The trees shown in the illustration, and which were of average height and close to the mine, form a fairly good gauge of the height to which the earth was thrown. The next experiment, which was the first on the river side, was the explosion of a 4oz. cartridge under water, which was thrown to a considerable height. The last demonstration was intended to consist of the explosion of roburite, gunpowder, and dynamite in an explosive mixture of gas and air, an old boiler being provided for that purpose. Unfortunately time was too far advanced to admit of this experiment being carried to the end, the roburite only being exploded. This is the more to be regretted, as this experiment might have shown the advantage of roburite over gunpowder and dynamite in not igniting gases, this being the chief feature claimed. The roburite certainly did explode without igniting the mixture contained in the boiler, but it would have been interesting and instructive to have seen the behaviour of the other two explosives mentioned under exactly similar conditions. It may here be mentioned that in none of the experiments was a flame visible, a light brownish smoke only being produced. Practical experience alone can now show in how far the roburite fulfils the last mentioned property claimed for it.

Reviews.

Practical Arithmetic. By Samuel Young. Manchester: John Heywood.

The author of this work is right in claiming that there is more information concerning transactions in cotton spinning, engineering, and manufacturing generally contained in this book than in any hitherto published treatise on arithmetic. The materials used in the examples are taken from modern trade, and there is hardly a trace of antiquated and obsolete methods of business. We are also glad to see that the author does not propose in his examples any of those impossible or ridiculous transactions which mar the usefulness of so many books on arithmetic. The numerous varied examples form the real value of this book, and we can heartily recommend its use to anyone who wishes to attain an expertness in calculation. The weak point of the book is its lack of breadth and thought, which shows itself in the bareness and incompleteness of the explanations of rules and principles. We hope that this fault may be remedied in a future edition.

Elements of Metallurgy. By J. Arthur Phillips, F.R.S., F.G.S., &c. New edition, Revised and Enlarged by the Author, and H. Bauerman, F.G.S. London: Charles Griffin & Co. 1887.

The first edition of Mr. Phillips' "Manual of Metallurgy" appeared in 1852, the second in 1854, and the third in 1858, up to which latter date no other work on the subject had been published in England. Thereafter a considerable number of treatises appeared, some of them very large, and consequently expensive, while others confined themselves to the metallurgy of one of the metals only. The first edition of the present work was issued in 1874, and was intended to give in a single volume with considerable detail the metallurgical operations relating to all the principal metals, and at the same time to serve as an introduction to the general literature of metallurgy. The work was essentially a new work, and not merely a revised edition of Mr. Phillips' "Manual." Its object was to supply, within moderate limits, such practical information on general principles and typical processes, as might not only afford a comprehensive view of the subject, but also enable the reader to study with advantage more elaborate treatises and original memoirs; and the information was brought up to date as far as possible. The author was engaged on a new edition at the time of his death, and this has been completed and superintended in its passage through the press by Mr. Bauerman, who is well known for his writings on metallurgical subjects. The chief advances in metallurgy during the past ten years have been recorded, and large additions and alterations have been made, especially in the section relating to iron, although many notable additions are also to be found under the heads of copper, lead, silver, and gold, dealing with the newer developments in processes for the smelting and extraction of those metals from their ores; while in revising the text, notices have been removed of several processes which have either failed in practice or become obsolete. The work contains sections on the physical properties of metals, fuel, refractory materials, iron, copper, tin, zinc, mercury, lead, silver, gold, and platinum, as well as on the rarer metals; and the space which is given to each is well proportioned to their importance from an industrial point of view; and altogether we can recommend the book as the most generally useful treatise on metallurgy, for its size, which has yet been written.

Counsel's Retainers. By E. B. G. London: William Clowes & Sons, Limited.

In this modest little pamphlet a mass of unwritten law is reduced into twenty-five rules. The general public will learn with interest the distinction between, and the peculiar virtues of general and special retainers, the fees payable in each case, the circumstances under which retainers are revoked, and the extent to which they entitle a client to the counsel's services. A favourite character of the author is the cautious solicitor. He, of course, knows all about retainers; but the articled clerk, who hopes in time to develop into one of these ornaments of the human race, might do much worse than study these pages. Struggling barristers will wonder why, if a retainer costs so little, they so rarely see one; and smile sardonically at the writer's warning that a special retainer, if accompanied by the requisite fee, cannot be refused unless another party to the action has already given a retainer, whether general or special. There is room in certain passages for improvement of style, but it is hypercritical to expect literary elegance in books dealing with legal subjects.

Screw Threads. By Paul N. Hasluck. London: Crosby Lockwood & Co.

This is a small illustrated pocket treatise, containing seventy-nine pages of closely printed matter, on screw threads and methods of producing them. The author deals, in successive chapters, with screw threads in general, dies and die stocks, screw cutting in the self acting lathe, cutting complex thread rates on self acting lathes, and tap making. The book will, no doubt, be found to contain much that is useful to the intelligent workman, who is desirous of thoroughly mastering that part of his craft with which the book deals. Since the work under consideration is not merely a book of reference, but constitutes essentially a treatise, it might, we think, with advantage have been brought out in a more readable form, the size, both of the book and type, being too small and inconvenient for practical use.

Tables and Memoranda for Mechanics and Engineers. By Francis Smith. Fourth edition. London: Crosby Lockwood.

This little volume contains a surprising amount of information useful and interesting to both master and workman. In addition to the usual rules and tables for mechanical engineers, we find therein some leading facts connected with wood work, plumbing, slating, plastering, hydraulics, &c., together with a detailed account of the various special weights and measures used in England. The articles on "Trigonometry" and "Surveying," however, are somewhat deficient as regards treatment; and the same may be said of the treatment of the foreign money and exchanges.

Some National and Board School Reforms. Edited by Lord Brabazon. London: Longmans, Green, and Co. 1887.

The editor of this book has long taken an interest in public questions; and believing that many of our several evils would in a great measure be removed if an improvement were to be effected in our national system of education, by the inclusion in the Government code of physical, technical, and industrial training, and wishing to hasten this reform, he has re-published in a cheap and popular shape some of the most recent expressions of opinion on the subject. These consist of papers which have appeared in various reviews and newspapers, and their publication in a collected form will be welcomed by all educationists. The first is by Lord Brabazon himself, and is on "The Health and Physique of our City Populations," a subject which is now beginning to demand special attention. The second paper is by the same author, on "Open Spaces and Physical Education," and may be looked upon as supplementary to the first. There are various other papers on elementary education, but

Digitized by Google

those to which we wish to direct special attention are contained in the second part of the book, and relate to technical and industrial training; and among the authors there are Samuel Smith, M.P., Sir Philip Magnus, W. Fowler, M.P., H. Cunynghame, Professor Huxley, and the Marquis of Hartington. The speeches and letters of the two latter on the occasion of the inauguration of the National Association for the Promotion of Technical Education attracted considerable attention, and they are here reproduced, with the articles which appeared in the *Times* on them. Miss Evelyn Chapman gives an account of the Slöyd system of education as practised in Sweden, and, from observation of it, she is convinced of its excellence, of its claim to be regarded as an important factor in education, and the need there is for something of the kind in our own schools; and, among others, Lady Leigh puts in a powerful appeal for the better training of girls. We agree with the editor when he says that if such reforms as are advocated in these pages were effected, the future generation, furnished with the means of leading industrious, prosperous, and happy lives, would find itself in a much superior position to the present, which, being nourished mainly on intellectual food, finds its body starved and its hands paralysed.

SELL'S DICTIONARY OF THE WORLD'S PRESS AND ADVERTISER'S HAND BOOK. London: SELL'S ADVERTISING AGENCY, Fleet-street. 1888.

We certainly think that this work is one of the cheapest of our publications, for the book contains thirteen hundred pages, and only costs two shillings. There is a complete list of all the newspapers, periodicals, and magazines published throughout the world, and to each one is appended some definite and accurate information about the circulation, the views expounded, the scale of charges for advertisements, and the nature of the trade reports which appear in its pages. The press of the British Isles is noticed and described more fully, and greater details are entered into as to the industries which form the staple trades of the districts in which the papers circulate. The present volume also contains several valuable articles, which have been specially written for this work, including "Hints on the Law of Libels in Newspapers," by Dr. Blake Odgers; "The Rise of Provincial Journalism," by Mr. H. R. Fox Bourne; "Some Newspaper Men," by Mr. J. W. Robertson Scott; and "The Centenary of the *Times*," by Mr. John Astle. Among the other features of the book, may be mentioned a series of portraits of sixty-four "heads of the press," in England, France, and America, the history of each of the London daily newspapers, and a collection of old advertisements. The book is both valuable for reference and interesting to read; but it is evident that the chief purpose which it is intended for, is to serve as a hand book for advertisers. There are many practical hints on the art of attracting attention by the aid of blocks and type, and the information about the various newspapers is exactly what is desired by an intending advertiser. If there is one article in the book to which we may take exception, it is the account of the modern mechanical type composers. There is no mention at all of the latest improvement in this direction, viz., The Thorne Company's machine, which was exhibited at the American Exhibition at London last year, and described in *Industries*, Vol. III., page 69. The Thorne machine has lately been adopted by some provincial newspapers. Nevertheless, Mr. Sell's book should circulate among all classes, for it is the handiest and most complete compilation in connection with the art and business of advertising which has yet been published.

PRACTICAL EDUCATION. By Charles G. Leland, late Director of the Public Industrial Art School, Philadelphia. London: WHITTAKER & Co. 1888.

The name "practical education" is now generally understood to mean a training in some departments of practical work, and therefore synonymous with what is usually understood by technical education. Mr. Leland's book, though it is based on the teaching of art, is neither a scientific nor technical manual. It begins with an elucidation of the principles involved in art education, and from those as a foundation it evolves the rational method of teaching. The author remarks that education, as it at present exists, consists in storing the memory, developing the intellect, and training the constructive faculty. He goes a step beyond this, and shows how the memory may be created, quickness of perception awakened, and the constructive power formed, so that the mind, when it begins to acquire knowledge, may do so with confidence and strength. In short, he keeps in view throughout a popular analysis of mind, and insists that children, before learning, should acquire the art of learning —that is, that we should *intellectualise* them before attempting to improve their intellects. Mr. Leland's method is, in fact, a development of the kindergarten. He argues that if a child can learn in the kindergarten to sew, sing, braid, draw, and model, it can in a more advanced school study more advanced subjects, and all the more so, because the whole system does not depend on learning different branches, but because the necessity of design and modelling is the same for every art study, be it in wood, clay, sheet brass, paper, or even embroidery. That is to say, these different branches are not taught directly as bearing on particular trades, but simply as means of educating the mind, the eye, and the hand, and thus lay the foundation for proficiency in all trades. This is practically all that can be done in the way of technical education in elementary, and, to a large extent, in secondary schools. Mr. Leland dwells on the importance of freehand drawing, but not in the manner in which it is usually taught, by mere mechanical copying, but in such a way that from the first lesson in which the children are taught to throw lines freely and accurately, they are made to exercise their inventive faculties, or to design. As by the ordinary system the child too frequently wearies of drawing, by this it is step by step made familiar with variations upon given motives or patterns, so that it can in a few weeks or months develop entirely original patterns. By a union of drawing and the minor arts, the eyes and the hands are trained, and through them the intellect developed, and at the same time the pupils are prepared for every practical occupation. Mr. Leland's school was from the beginning an experiment to fully ascertain what children could do, and not simply an institution to teach art. A want of appreciation of this fact on the part of the public has been the source of the only troubles which the school has experienced. A common outcry has been—at least in America—"Teach boys while at school a practical trade by which they can get a living." Whereas the Leland experiment was made solely to find out what boys and girls are capable of learning. The result has been to prove beyond doubt that all children taking one or two lessons, of two hours each in a week, in an *atélier*, can in two years' time learn, not one but several arts, so well that they can obtain paid situations on leaving school. The book abounds with examples of methods, and with clear statements of principles which are worthy of the careful study of all engaged in the work of education, and to such we cordially commend it. An appendix containing a list of the principal works on technical education will be found useful to the same class of readers.

THE CORNELL UNIVERSITY REGISTER, 1887-88. Published by the University, Ithaca, N.Y.

In our first volume (page 566) we gave an account of the Engineering Department of Cornell University, so that we need not now enter into details regarding it. We are, however, much pleased to see that progress continues to be made, and that at a rate which in this country would be considered astonishing, thanks both to State and private liberality. In addition to the subjects which are usually included in the branches of University education, Cornell University has taken up those which are generally called technical, and it is rapidly becoming an important engineering school. Out of a total of 1022 students, 33 have chosen Agriculture, 55 Architecture, 111 Civil Engineering, 83 Electrical Engineering, and 136 Mechanical Engineering. Of the latter department Professor Thurston is the director, and a special college, founded by the Hon. Hiram Sibley, is devoted to it, and every facility is given both for theoretical and practical investigations. The former consists of the study by text book and lecture of the materials used in mechanical engineering, the valuable qualities of these materials being exhibited in the mechanical laboratory by the use of the various kinds of testing machines, as well as by examination of specimens of all the most familiar grades, of which samples are seen in the cases of the museums and lecture rooms. The theory of strength of materials is here applied, and the effects of modifying conditions—such as variations of temperature, frequency and period of strain, method of application of stress, are illustrated. This course of study is followed or accompanied by instruction in the science of pure mechanism, succeeded by that of machine design and the theory of the steam engine and other motors, all being applied to designs in the drawing rooms. The last term of the regular course is devoted largely to the preparation of a graduating thesis, in which the student is expected to exhibit something of the working power and knowledge gained during the course. A *graduating piece* is demanded, also, of each student, both in the drawing room and the workshop, which shall show proficiency in this department. In the mechanical laboratory the work is conducted by an instructor familiar with its apparatus, and with the best methods of work, who plans a systematic course of instruction that is intended to give the student not only skill in the use of apparatus of exact measurement, but to teach him also the best methods of research, and to give him a good idea of the most effective methods of planning and of prosecuting investigations, with a view to securing fruitfulness of result with minimum expenditure of time and money. An institution conducted on such principles is sure to be successful. The same thoroughness pervades all the other sections of the University, and it now draws students from all parts of the world, a few even from England.

THE LEAMINGTON CENTRAL ELECTRIC LIGHT STATION.

THE credit for having given the first impulse to the introduction of the electric light into Leamington, is due to two members of the Town Council, Messrs. Fell and Bright, who, after seeing the lighting of the Birmingham Art Gallery, which was carried out by Messrs. Chamberlain & Hookham, Limited, were desirous of introducing the electric light into their own houses, and suggested that this firm should establish a central station in Leamington. Eventually the Midland Electric Light and Power Company, Limited, was formed, and a station was built on a site in Wise-street. The company had secured from the Town Council the right of way for laying their cables under the streets, and by October last year the work had so far progressed that a portion of the streets and some private and public buildings could be lighted. The lighting was carried on experimentally until Christmas, 1887, and from that date the regular service was commenced and has continued to the present time. Thus far the history of the Leamington installation presents nothing very remarkable. In all similar undertakings there must be a certain amount of experimenting until the service can be finally organised; but the remarkable thing about Leamington is that now, when the installation is in full working order, complaints against it are louder than during its experimental stage. These complaints emanate from the party who are opposed to the electric light, not on its own merit or want of merit, but because their political opponents are in favour of it. In Leamington every local question is taken up as a matter of politics and fought over in a political spirit, which, we need scarcely say, is not calculated to bring out much fairness or do justice to technical points where the question is one of scientific or industrial importance. In the case of the electric light installation, the opposing party have done their best to disparage the work, both in the Council Chamber and in the local Press; and as these unfavourable statements have from time to time been reproduced in some technical journals, the electrical engineering profession at large finds itself somewhat puzzled what to think of the Leamington Central Station. It was with a view to judge for ourselves that we, last week, paid a visit to Leamington, and inspected the electric lighting arrangements, Messrs. Chamberlain & Hookham having courteously given us permission and every facility to see all their work.

The station is a building 90ft. square, and stands close to the Warwick Canal on a piece of land large enough to permit a future increase of the building to two or three times its present size. There are at present fixed two steel boilers, locomotive type, each 5ft. barrel by 19ft. long, having a total of 770 sq. ft. of heating surface; and two horizontal compound condensing engines, each of 200 effective h.p., with cylinders 15in. and 26in. diam. by 2ft. 4in. stroke. These engines, as well as the boilers, have been supplied by Messrs. Robey, and are provided with the Proell cut-off gear, controlled by Richardson's electric governor. The boilers are designed to work at a steam pressure of 140lb. per square inch; but only 120lb. is now carried, this being sufficient for present requirements. There is a partition across the engine room, so placed that the barrels of the boilers are in the engine room proper, whilst the fire boxes are on the other side of the partition in what may be described as the boiler room, this arrangement having been adopted to keep the dust and dirt of the stoke room from the machinery. Each boiler has its own injector, and in addition there is a feed pump common to both. Room is provided for a third engine and boiler, and the steam pipe is common to all the boilers, so that any engine can be worked by any boiler. The engines have 9ft. fly wheels, provided with nine grooves, each taking a cotton rope $1\frac{1}{2}$in. diam., known as the Lambeth cotton rope, made by Mr. Thomas Hart, of Blackburn, for which it is claimed that it will not stretch, the fibres being laid together without twist. These ropes drive on to 4ft. followers on a 6in. main shaft, on which are four 6ft. pulleys with four grooves for ropes of the same size, by which the power is transmitted to four Chamberlain & Hookham shunt-wound dynamos. These machines are each of 800 lights' capacity, and two of them are at present sufficient to supply the whole demand of current for about 1100 lamps out of a total of 1500 lamps wired. During the day time current is supplied by two storage batteries, each consisting of sixty-three E.P.S. cells of the 31 L 1888 type, giving a maximum discharge of 70 ampères. These batteries are charged by two 10 kilo-watt dynamos driven by a 30 h.p. Robey high speed engine. In this case also the transmission is by cotton ropes, the dynamos being set

Digitized by Google

in line with the driving pulley between them. The driving pulley is carried on a short spindle, and connection with the dynamo spindles is made by flexible couplings of Mr. Hookham's design. The charging current is stopped when the lighting is done from the batteries, and the pressure is regulated by including a larger or smaller number of cells between the terminals of the two feeders; but arrangements are now being made to keep the number of cells constant, and to regulate the pressure by sending the current through a rheostat in the manner adopted in some of the Edison stations. By this means the contractors hope to obtain a more delicate adjustment of pressure, and to avoid injury to the end cells, which at present get charged and discharged unequally.

The current from the large dynamos is led to a main switch board consisting of enamelled slate set in an iron frame, and carrying a number of Drake & Gorham's ring contact switches, by means of which any of the four dynamos can be coupled to any of the two pairs of feeders, two dynamos and one engine only being at work simultaneously, the other set of two dynamos and engine being in reserve. There is also another switch board of similar construction, by means of which the coupling between the charging dynamos and the batteries, and between the batteries and the feeding mains, is effected. On this switch board are two electromagnets which cause a bell to ring when the discharging current from either of the batteries exceeds 70 ampères, thus giving the attendant warning that the large engine must be started to supply the growing demand for current as the evening advances. The routine of the station is as follows: From dawn until dusk the batteries are coupled to the feeders and the engines are stopped. The consumption of current during the day time is very small, but the pressure is always on the wires, so that private consumers can have the light at all times except once a month, for an hour or so, when the cables are being tested for insulation, conductivity, &c. Towards the evening, as soon as the electric bell has given warning to the attendant that the current in the feeders has increased beyond the capacity of the battery, he starts one of the main engines and two dynamos, and switches the dynamos into circuit. This can be done without any interruption in the lighting, the dynamos and batteries being coupled in parallel for a short time, after which the batteries are switched off. The feeders are then supplied from the large dynamos direct, and the charging dynamos may now be started and the batteries again charged up, so as to be ready for a day's supply on the morrow.

The distributing plant was originally laid down on the three-wire system; but owing to the great complications entailed by this system, both in the station and on the consumers' premises, it has been changed to the ordinary two-wire system. The change was effected in the feeders by coupling the balance wire to the negative or return wire, and in the distributors by coupling the positive and negative wires together to form the out circuit, and using the balancing wire as the return. The current is supplied to the town by two lines of feeders, one 900 yards and the other 460 yards long. The sectional area of the cables is respectively 375 and 300 sq. mm. The feeders are laid in brick trenches 2ft. square placed 5ft. under the level of the road. The trenches are covered by 3in. Yorkshire flags, and above them there is therefore about 3ft. of earth and paving. The cables are of Callendar's make, and are supported in cleats of paraffined wood which rest upon slate shelves clear of the bottom of the trench, so as to keep the cables above any water which might accumulate at the bottom. Provision is, of course, made for draining away any water which might find its way into the trench. The feeders which start from the main switch board in the station, terminate at two iron distributing boxes placed above ground in the streets, and all the connections with the distributing mains are made in these boxes. The distributing mains themselves are also carried in brick trenches 15in. square, and the longest service reaches the house of Mr. Fell, the Mayor, which is about 1860 yards from the station. The section of the distributing mains varies between 120 and 60 sq. mm., according to the distance and the number and size of houses lighted on the way. The service wires to the houses are all permanently connected with the distributing mains underground; but no junction boxes are used, the connection being simply made to the mains within the trench and well insulated. The distributing mains for the lighting of the street lamps are controlled from the two distributing boxes, the connections being arranged so that out of a total of 183 electric street lamps, eighty-three can be turned out separately. This at present is done at 11 p.m., and the 100 remaining lamps are turned out at 1 a.m. The Town Council pay £2. 2s. per annum for each street lamp, the total lighting time being 2860 hours. This sum covers renewal of lamps. The street lamps are nominally of 16 c.p. This is decidedly too small a candle power to produce a good effect, and the arrangement of the lamps is also open to objection. The lamps are fixed to brackets projecting at right angles from the lamp posts; but these brackets are alternately turned parallel to the direction of the street and at right angles to it, so as to bring the lamps over the footpath. When looking down the street, this gives a most untidy appearance to the lighting. Some of the lamp posts carry three brackets, set at 120° from each other, and this arrangement has a rather pleasing effect. The great mistake, in our opinion, was to employ lamps of 16 c.p., and perhaps less, for street lighting. An ordinary gas jet has quite that power, and thus in point of light there is no advantage whatever in replacing it by a small glow lamp. Considering the great expectations usually entertained about electric lighting, the inhabitants may well be excused if they feel disappointed at the electric light as now supplied to their streets, and in so far the anti-electric light party of Leamington has some reason for complaining. On the other hand, it should be stated that the arrangement of the lamps and their candle power were not left to the discretion of the contractors, but were prescribed by the town authorities.

Having criticised adversely the street lighting, we are glad to be able to give unqualified praise to the indoor lighting as carried out by Messrs. Chamberlain & Hookham. By the courtesy of the Mayor of Leamington, we were enabled to inspect his own private installation, and also that of the Town Hall, and in both instances the lighting is excellent. The assembly room in the Town Hall is, as far as our experience goes, the best lighted hall in this country. It is 80ft. long, by 40ft. wide, and 28ft. high, and the whole of the lighting is done from above by 186 lamps set in five circular clusters on the centre line of the ceiling. Each lamp is surrounded by a reflector of silvered glass somewhat resembling a large egg cup turned with the opening downwards, the rim being slightly above the bottom of the filament. The curve of this reflector is so chosen that no rays are reflected vertically downwards, whilst the number of rays reflected in a slanting direction increases as the angle of the ray to the horizontal decreases. This represents the curious effect that to an observer standing immediately under the first cluster this appears less bright than the next and the following clusters. In fact, the furthest cluster of lights appear the most brilliant, and the practical effect of this arrangement is that every corner of the hall is as brilliantly lighted as any part of the floor immediately below the lamps. By this peculiar arrangement of reflectors, which has been devised by Mr. Hookham, the light is perfectly diffused. The staircase, council chamber, and other rooms are also very tastefully lighted, the total number of lamps fixed in the Town Hall being 360. The current consumed is measured by two of Mr. Hookham's new meters, which we shall presently describe. In the pump room there is an installation of 170 lights, also supplied with two meters. As regards smaller installations, the testimony of the shopkeepers in Leamington is unanimously in favour of the electric light. Tobacconists find that since they have abandoned gas their stocks of cigars exposed in the shop windows keep saleable, and are not deteriorated through the moisture and heat emanating from gas jets. In a jeweller's shop, we saw some very pretty effects produced by incandescent lamps placed within the shop windows close to the exhibited articles, but screened from the observer outside by semi-opaque shades. As regards the application of electricity for motive power purposes, up to the present there is only one example in Leamington, viz., a small motor used by a dentist; but Messrs. Chamberlain & Hookham are confident that before long there will be a good demand for motors, to be used by drapers for working sewing machines, and by printers. A small motor is also to be erected at the Central Station for driving a lathe and other tools which are required for small repair jobs to be done on the spot. Whilst noticing the use of the electric light in the shops of the town, we must not forget to mention the town office of the contractors, which is situated near the Town Hall. This office, besides serving as a show room for lamps and fittings, and for the commercial business of the company, is also used as a point of control for the work done at the Central Station. The office boy there has the duty to record every hour, between 6 p.m. and 10 p.m., the pressure kept on the mains, and the nightly record thus obtained gives the engineer in charge a means to find out whether the attendant at the station has properly done his work. We were allowed to examine the log book, and append here a copy of two of the entries taken at random. On the 10th June, the entry is as follows:—

Time, p.m.....	6	7	8	9	10
Pressure, volts....	112	112	112	111	111

On the 14th June the record is:—

Time, p.m.....	6	7	8	8-45.....	10
Pressure, volts....	113	110	111	111	113

It will be seen from these figures that the pressure kept in the mains is remarkably uniform, and this explains, to a certain extent, the satisfaction felt with the service by private consumers.

The means employed to obtain this result are exceedingly simple. As we have already stated, there are two feeders going out from the station to two distributing boxes. Each feeder is supplied by one battery in the day time, and by one dynamo at night. The dynamos are not coupled together at the station, but each delivers current independently to its feeder. To each feeder is attached a compound Schuckert voltmeter, made with a specially wide scale in the range of 100 to 130 volts, so that the pressure can be accurately read off. The main current passes round the voltmeter in one loop, formed of a stout copper rod, and the loop is so connected that the main current tends to turn the needle in opposition to the current in the shunt coil of the voltmeter. The adjustment of these compound voltmeters is exceedingly simple, and consists in raising or lowering the whole instrument within the fixed loop until the exact balance is obtained. The voltmeter is then fixed in this position, and indicates not the pressure at the station, but that at the distant distributing box. The e.m.f. of each dynamo is adjusted by means of a rheostat in the exciting current. This rheostat is from time to time adjusted by the attendant according to the indication of the compound voltmeter, the duty of the man being simply to keep the voltmeter at 110 volts. This forms the final adjustment; but within certain limits the adjustment is automatic, and is performed by the Richards governor which controls the speed of the main engine. According to the load the speed varies from a minimum of 84 revolutions when the demand for current is small, to a maximum of 90 revolutions when the demand is largest. Since the load is fairly distributed between the two feeders, and since the ratio of load between them can only vary within narrow limits, the final adjustment to be made by the attendant is required within equally narrow limits, and his task is rendered still more easy on account of there being added a pair of connectors between the two distributing boxes, so that any sudden and excessive demand upon one box is in part supplied from the other. By means of these regulating devices, the work at the station is simplified to such an extent that no special skill or extraordinary attention is required on the part of the man in charge, and this also explains the remarkably small variations from the standard pressure which will be apparent from the figures we have given above.

The most interesting part of the installation is, perhaps, the new Hookham meter, which is used both as a station and as a house meter. Briefly described, the meter consists of a dynamo with a disc armature containing no iron, and revolving between the poles of a permanent magnet of tungsten steel. The strength of field is about 1200 C.G.S. units, and the armature is set in rotation by passing either the whole or a definite portion of the main current through it. To one side of the armature is attached a solid copper disc, which is thus carried through the field as the armature revolves, and the eddy currents produced in this copper disc tend to retard its motion. Without going into the theory of this very ingenious meter, we may say that, apart from certain small disturbing causes, the number of revolutions performed by the disc in a given time is exactly proportional to the quantity of electricity which has passed in the same time. The revolutions of the disc have, therefore, only to be registered upon a counter in order to obtain a record of the current supplied during each quarter. For convenience, the counter is arranged to register Board of Trade units. The calibration of the meter to Board of Trade units is exceedingly simple. In most cases only a small portion of the main current is passed through the meter, and the latter is calibrated by increasing or diminishing the resistance of the shunt which carries the greater portion of the current until the counter shows correctly Board of Trade units. All the larger consumers have meters of this description, and they pay for the current at the following rates: When from 1 to 40 units have been consumed per quarter, the charge is 8d. per unit; between 41 and 150 units, the charge is 6d.; and from 151 upwards, the charge is 4d. At these rates the cost per lamp hour varies from ·54d. to ·27d., according to the amount of electricity used. We may notice that the electric light installation at Leamington has had a very salutary effect in a direction not contemplated by the contractors. We have it on the authority of a leading citizen, that since the introduction of the electric light the candle power of the gas supplied has improved from 15 c.p. to 16¾ c.p.; whilst at the same time the previous price of 2s. 9d. per 1000ft. has been reduced to 2s. 7d., representing an annual saving to the consumers of gas in Leamington of £1,200. After our visit and inspection, we are glad to be able to state that the electric light installation at Leamington is by no means the dismal failure which the local Press and some technical journals have made it out to be. On the contrary, it is a modest yet fairly successful attempt to supply a public want; and the enterprising townspeople of Leamington are quite ready to take advantage of the facilities thus offered them.

BELT GEAR FOR TESTING DYNAMOS.

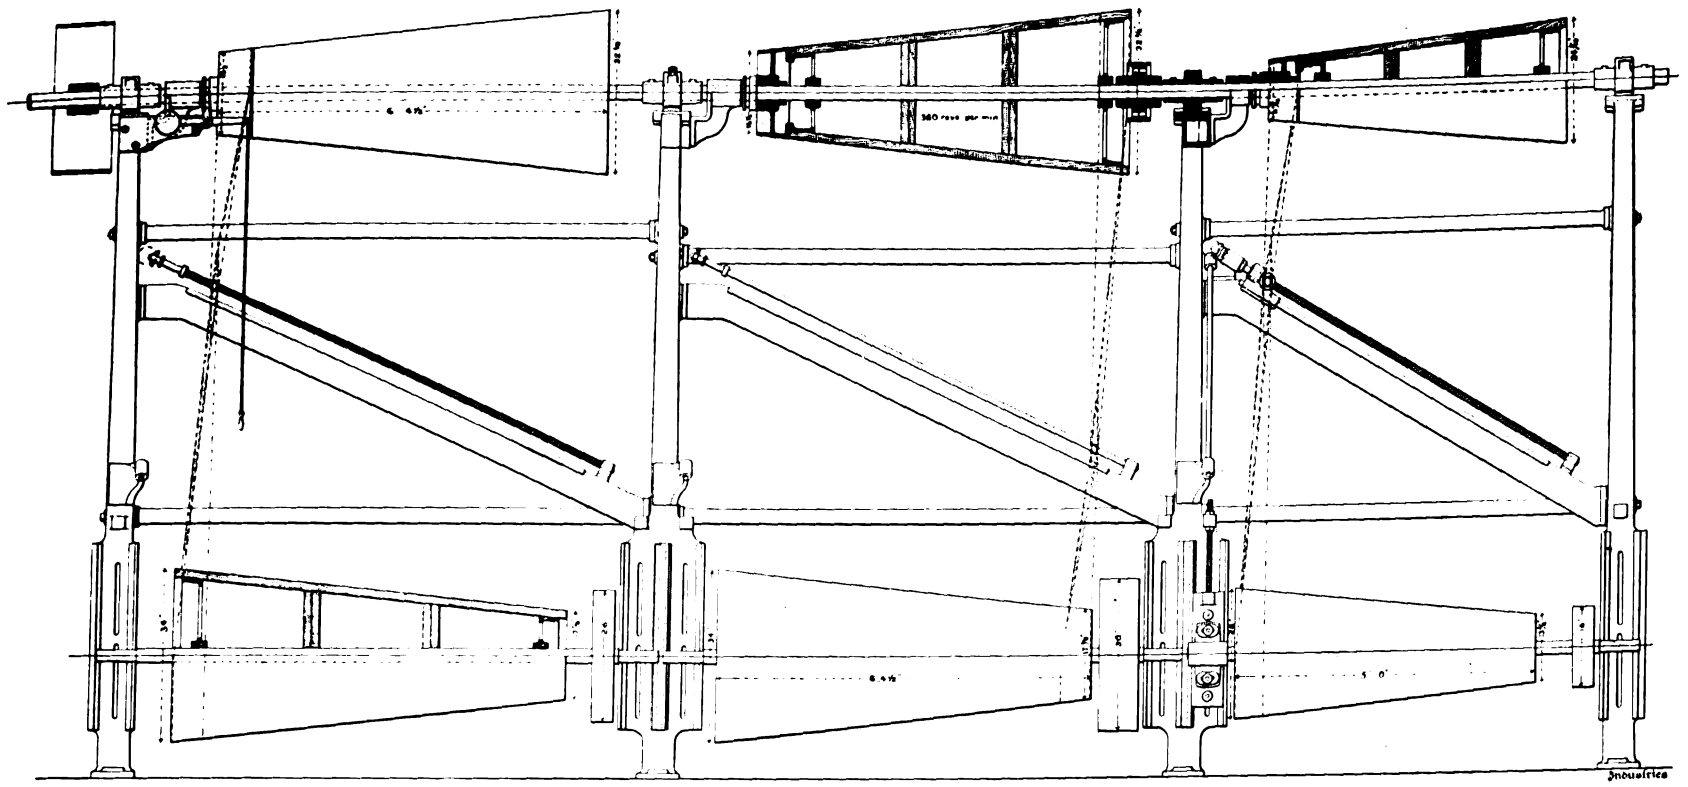

FIG. 1.

BELT GEAR FOR TESTING DYNAMOS.

THE employment of heavy currents in laboratory experiments and the testing of dynamo machines have of late years become so necessary portions in the curriculum of electrical engineering students, that most schools have now more or less complete plants of dynamo machines and driving gear at their disposal. One of the most complete installations of this kind is that at the Central Institution of the London and City Guilds in South Kensington, and as the driving gear there employed may with advantage be adopted elsewhere, we publish herewith a sketch of it. Fig. 1 shows the gear partly in front elevation and partly in section, and Fig. 2 shows an end elevation. The gear has been made by Messrs. A. Ransome & Co., of Chelsea, to the designs of Professor Ayrton, who was assisted by Mr. Mather, and has, since its erection some eighteen months ago, proved perfectly suited for the work carried on at the laboratory in the Central Institution. Power is supplied by an 8 n.h.p. Marshall semi-fixed engine, running at 180 revolutions per minute. A belt from the fly wheel drives on to the pulley on the left hand end of the top shaft, giving the latter a speed of 360 revolutions a minute. On this shaft are keyed three cones, each consisting of an iron frame with a wood lining outside. Similar cones are mounted on separate shafts below, which are adjustable vertically, so that the belts may be tightened. The ratio of diameters is such that the speed of each lower cone may be varied between the limits of one to three. Three dynamos can be simultaneously tested, and the speed of each can be varied through this range. Thus if the minimum speed required for one dynamo be 500 revolutions, the maximum speed obtainable without interfering with the other dynamos will be 1500 revolutions. If the minimum speed required for dynamo No. 2 be 600 revolutions, this same machine can be run at any speed between 600 and 1800 revolutions, and similarly the third machine can be worked between the limits of 670 to 2000 revolutions. Two pairs of cones are of equal size, and the third pair is somewhat smaller. The larger cones have been used to transmit up to 14 h.p. each, and the smaller pair has been used up to 6 h.p.; but they are capable of transmitting 10 h.p. An important and valuable feature of this design consists in the support of the belt on a separate loose pulley when the gear is not used. This loose pulley forms a prolongation of the narrow end of the cone, and is supported upon a separate sleeve surrounding the shaft, but not running with it. This sleeve is held by a bracket at the side of the bearing as shown. If the belt be shifted to the left, so as to lie wholly on the pulley, the shaft with the upper cone keyed to it runs idle, and the lower cone remains at rest. There is consequently no waste of power through friction. If it be desired to start the lower cone, the handle shown in our illustration is pulled downwards, and by this means the conical pulley is pressed against the face of the cone, and by virtue of the friction between the surfaces commences to revolve. At the same time the belt shifting gear is set in motion, and thus the belt is shifted on to the cone itself. As soon as the cone takes hold of the belt the handle may be released, and the belt may be set on to that portion of the cone which will produce the

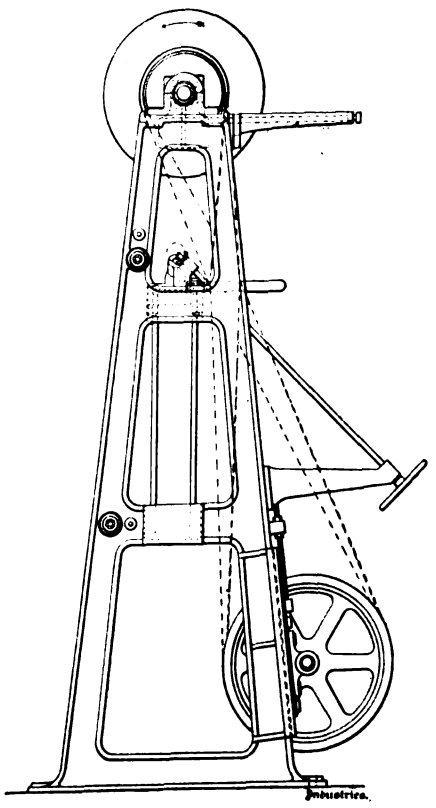

FIG. 2.

required speed. Thus the friction clutch is only brought into action at the moment of starting, and there is, therefore, no permanent waste of power through friction, nor the danger of a heated collar bearing, as is the case in ordinary friction clutches. The shifting of the belt is performed by a roller inserted into the crossing place of the belt. The roller is held on a stud which can be shifted to the right or left, by means of a screw and nut controlled by a hand wheel, as shown in Fig. 2. The screw is inclined diagonally across the frame supporting each pair of cones, as the height of the crossing point of the belt naturally varies with the horizontal position of the belt. By means of the hand wheel it is possible to maintain the speed of each dynamo practically constant, notwithstanding great variations in the power required by the machines under test, and the consequent irregularity in the speed of the engine. It is therefore possible to adjust the speed of each dynamo so as to obtain either a constant current or a constant pressure: conditions which are essential for certain experiments, and which are not fulfilled by ordinary compound wound dynamos worked from an engine which is governed by a centrifugal regulator.

COMBUSTION OF COAL.*

THE presence of combustible gases in the products of combustion is certainly a proof of the deficient utilisation of coal. The defective methods used to collect the products of combustion have often led experimentalists to neglect the presence of combustible gases. M. Scheurer-Kestner thinks this a serious matter, and has taken care, when collecting these gases, to guard against sources of error. He finds the quantity of air most favourable to combustion, by beginning with a volume smaller than the theoretical quantity required, and increasing it until it exceeded the maximum which could be well used. He determined that if from 8 to 9 cubic metres of air are employed for the combustion of 1 kilo. of Rouchamp coal, carbon monoxide and perhaps pure hydrogen and carburetted hydrogen would be found among the gaseous products of combustion, and that from 6 to 18 per cent. of the carbon contained in the coal was lost; if from 10 to 12 cubic metres of air are allowed, the loss was only from 4 to 6 per cent.; with 12 cubic metres it is only 4 per cent.; while with 15 cubic metres it is reduced to 1 or 1½ per cent.

Practice, he stated, had already given useful data on this head; but the important fact to establish was the precise limit when the loss was the least, and the gain the greatest. He found that the furnace should be fed with a volume of air about 5 per cent. more than the theoretical quantity required for the combustion of the coal.

In regard to the question of smoke, the following experiment, he thought, could not be too much recommended to persons disposed to complain of factory chimneys. He remarked: "In the course of a boiler experiment, I placed beside the apparatus containing the gases of combustion a glass tube open at each end, into which I had introduced a layer of asbestos from 25 to 30 centimetres thick, in such a manner that without exercising the least pressure, the gases were allowed to pass freely, and only the soot was retained. This tube was placed in communication with an aspirator, and the gases which entered were measured. The soot adhered to the asbestos, but only along a length of from 5 to 6 centimetres, the rest of it remaining perfectly clean. I was thus enabled to establish the proportion between the quantity of soot produced, and the quality of the coal consumed. But to anyone

* Abstract of a paper read by M. Scheurer-Kestner, before the Chemical Society of Paris.

Digitized by Google

who has not observed the fact, it is curious to note that however black and thick the smoke may be, even when purposely produced by feeding the furnace with insufficient air, it represents a loss of not more than 1½ per cent. of carbon in the coal; and if air be suffered to enter more freely, the loss resulting from the smoke falls to ½ per cent." M. Scheurer-Kestner, therefore, does not attach much importance to the generation of smoke so far as economy is concerned, and he only recognises two really efficacious systems: one based upon the continuous mechanical feeding of the furnace, and the other upon the combustion of smoke by mixing it thoroughly with very hot gases. In both cases the expense exceeds the economy effected by consuming the smoke. Of course there are frequent cases in which the necessity arises to have no smoke, and to employ apparatus to prevent its formation.

It may be useful to add the results obtained with a steam boiler of the French elephant type, with three tubes and a feed water heater. With the Rouchamp coal, taking the heat of combustion in the coal at 100 thermal units, the results were as follow:—

	Per cent.
Thermal units in the steam were	63·5
" " carried up the chimney...	5·1
" " in the combustible gases	4·9
" " in the soot.....	3·7
" " unaccounted for	22·8
	100·0

In more recent experiments 78·9 per cent. thermal units were obtained in the steam with coal "de la Ruche," and as much as 83 per cent. with a special Welsh coal sent by Mr. Donkin, of London. This loss, which ranges from 17 to 21·1 per cent. in the examples just given, is often more in practice, and must be attributed partly to the external radiation from the boiler, and partly to radiation from the brick work.

Notes.

RAILWAYS IN THE PHILIPPINE ISLANDS.

Consul Gollan, of Manila, reports that very little progress has been made with a railway between Manila and Dagupan, the concession for which was granted to an English company under a Government guarantee of 8 per cent. The prospectus of another line, the Centre of Luzon Railway, has been issued. The length of the proposed railway is 23¾ miles, and its course, in the immediate vicinity of Manila, would be through so populous and fertile a district, that no guarantee on capital is asked for from the Government, as it is thought that the traffic will prove sufficient to give a handsome return on the outlay. The required capital is estimated at £225,000.

COTTON IN CHINA.

A report has been prepared on the trade of Ssŭ-ch'uan, a province of China about which very little information is available, by Mr. Bourne, who was until lately the British consular agent at Ch'ungking. He states that home spun cotton is the leading clothing material, very few using any other textile. The foreign import trade was stationary for some years owing to bad harvests; but an improvement is now visible, both grey and white shirtings showing a large increase. Mr. Bourne suggests that much might be done to make British imports more suited to the wants of the province, and mentions as an example that the bales of cotton piece goods imported have to be re-made in smaller packages to cross the rapids.

A STEAM LIFEBOAT.

For several years the Committee of the Royal National Lifeboat Institution have been endeavouring to find a means of propelling lifeboats mechanically. In 1886 a special sub-committee conducted investigations to this end, but were eventually compelled to bring in an unfavourable report. In the following year the Committee offered gold and silver medals for designs for such a lifeboat; but, although there was a satisfactory response to the offer, the judges did not consider that any of the designs were of sufficient value to deserve an award. In the beginning of the present year, however, a model of a steam lifeboat was submitted to the Institution by Messrs. R. & H. Green, the well known shipbuilders at Blackwall, London, and after some modifications had been made in the designs at the suggestion of the Committee, this firm received instructions to build an experimental lifeboat on the proposed principle. The new boat will be 50ft. long, with 12ft. beam, and is to be propelled by a turbine wheel driven by an engine of 170 i.h.p. The Committee are to be congratulated on the energy and determination with which they have persevered in their endeavours, and we sincerely hope that their efforts may meet with success.

THE SKILLED LABOUR MARKET.

The Labour Correspondent of the Board of Trade reports that there is again a sensible improvement in the condition of the labour market, as indicated by the trade returns of certain societies of skilled workmen. Of such organisations twelve have supplied full details. These unions show an aggregate membership of 139,772, of which total 6678 were out of work—a proportion of 4·8 per cent. In the previous month the figures were 7352 unemployed for the same societies, a proportion of 5·3 per cent. There is thus on the month a decrease of 674 on the unemployed list, and a fall in the proportion of ·5 per cent. This improvement is chiefly due to the continued progress of the building and engineering trades, the former branches of industry especially being much better. The revival in iron shipbuilding seems to have reached almost a stationary point, as the figures are practically the same as those for last month. The labour market has, however, been disturbed in this trade by wages disputes, which may account somewhat for the lack of improvement. The cotton spinning trade is rather better, and some points of difference as to wages, which threatened to lead to serious disputes, have been amicably settled by advances to the workpeople. The steam coal trade has much improved; the number of unemployed is very low, and most of the pits are working full time. The reports may be generally summarised as five slightly better, two stationary, two good, and three moderate.

SOCIETY OF CHEMICAL INDUSTRY.

The annual meeting of this Society will be held in Glasgow on the 4th, 5th, and 6th July. On Wednesday, 4th July, at 11 a.m., a meeting will be held in the Bute Hall, Glasgow University, with the President, Professor James Dewar, M.A., F.R.S., in the chair. The business will consist in dealing with the report of the Council and treasurer, the election of office-bearers, the President's address, and other miscellaneous business, including the fixing of the place for holding the next meeting. The afternoon is left free for a visit to the Glasgow International Exhibition. At 6-30 p.m., the annual dinner will take place at the Grand Hotel, Charing Cross, Glasgow. For Thursday, 5th July, several excursions are planned. The first of them will proceed to the Forth Bridge Works and Broxburn Oil Works, where luncheon will be provided by the Broxburn Oil Company. The second excursion is divided into two branches, one proceeding to the Thornliebank Print Works, the other to the Langloan Iron Works (Messrs. R. Addie & Sons) and to the Summerlee Iron Works (Messrs. Neilson), where two different processes for recovering ammonia from blast furnace gases are in use. The third excursion will visit Nobel's Explosives Company's Works, where luncheon will be provided. On Friday morning, 6th July, a visit will be paid to Greenock to inspect Messrs. J. Walker & Co.'s sugar refinery. At 12-15 the steamer "Victoria" will leave the Prince's Pier, Greenock, for an excursion on the Firth of Clyde, returning to Glasgow at 6 p.m. Ladies are invited to join this excursion. Luncheon will be provided on board the "Victoria."

INSTITUTION OF MECHANICAL ENGINEERS.

The summer meeting of this Institution will be held in Dublin, on Tuesday, the 31st of next month, and following days. For organising the arrangements of the meeting an influential Local Committee has been formed in Dublin, of which the Right Hon. the Earl of Rosse is chairman, and Mr. Henry A. Ivatt and Mr. Samuel Geoghegan are the honorary secretaries. A similar committee is being formed in Belfast with the Mayor, Sir James H. Haslett, as chairman, and Mr. A. Basil Wilson and Mr. Bowman Malcolm as the honorary secretaries. The following is an outline of the provisional programme proposed by the Local Committees. On Tuesday morning, the 31st July, the President, Mr. Edward H. Carbutt, and the Council, together with the members of the Institution, will be received in Trinity College by the Right Hon. the Earl of Rosse and the members of the Local Committee. Papers will then be read and discussed. In the afternoon luncheon will be provided by the Local Committee in Trinity College. A steamer trip in Dublin Bay, or a visit to works in Dublin open to inspection, will fill up the afternoon. In the evening the Institution dinner will take place. On Wednesday morning the reading and discussion of papers will be continued in Trinity College, and in the afternoon luncheon will be provided by the Local Committee in Trinity College. Subsequently visits will be paid to the Great Southern and Western Railway Locomotive Carriage and Waggon Works, Inchicore, and to the Rathmines Water Works. In the evening there will be a conversazione. On Thursday Guinness' Brewery and places of interest in and around Dublin will be inspected, and in the evening members will proceed to Belfast. On Friday morning there will be a reception in the Belfast Town Hall by the Mayor, Sir James H. Haslett, and the members of the Local Committee, after which a visit will be paid to Messrs. Harland & Wolff's Shipbuilding and Marine Engine Works. Luncheon will be provided by the Local Committee in the Town Hall, followed by a trip on a steamer round Belfast Lough by invitation of the Belfast Steamship Company. In the evening a conversazione will take place in Queen's College, Belfast.

BREAKING UP OLD SHIPS.

The Norwegians have, according to our contemporary *Fairplay*, hit upon a new way of breaking up old wooden ships unfit for further use, the old method having long been felt to be a laborious and costly one. The new Norwegian plan is to loosely anchor the useless ship in a dangerous position near the coast, and to have her broken up to bits by the sea in the first heavy gale. The sea not only breaks up the ship but carries the results ashore, when they are collected and sold at good rates for firewood, &c.

ITALIAN IRON WORKS.

The iron works of the Genoa district are, according to a Foreign Office report, doing a very large business, and owing to the protection afforded by the additional duties are likely to increase their production. Messrs. Ansaldo and Co., of Sampierdarena, have in hand the engines and boilers for the "Sicilia," representing 20,000 i.h.p. In addition they have in hand an important order for castings and forgings for the Government, and a number of locomotives. Messrs. Raggio & Co., of Sestri, are now turning out rolled sheets, the work being done by men brought over from Birmingham. Messrs. Tardy, Benecke, and Co., of Savona, are extending their business in the direction of making steel rails and armour plates for ironclads.

CLIFTON SUSPENSION BRIDGE.

The *Bristol Observer* in an article on the above subject comments upon the great number of suicides committed by leaping from the bridge, and illustrates several suggestions for preventing any further occurrences. It states that since the opening of the bridge in 1864 as many as twenty-six cases have been recorded, all but one of which proved fatal. The fact that two suicides occurred within five days caused Mr. Pickersgill, M.P., to ask a question on this subject in the House of Commons. What effect this course may have on checking, or better still, on entirely preventing this fatal tendency, it is impossible to say; but public attention will at least be drawn to the necessity of providing some safeguard which would prevent people from throwing themselves from the bridge. We gather from the article in question that not only people bent on committing suicide, but also persons who are in no way anxious to prematurely terminate their existence, are seized with a strong inclination to try the fatal leap, and it is quite possible that a man on whose mind care heavily weighs may yield to the impulse of the moment, though he never thought of suicide before. The construction of an efficient guard is by no means an easy task. The weight of the material and the surface exposed to the pressure of the wind must be kept as small as possible, or they would seriously interfere with the safety of the bridge. On the other hand, the graceful outline of the structure, so seldom found in modern iron bridges, ought to be kept intact without incurring heavy expense. In the four devices illustrated in the article under consideration, wire netting is used by two designers and spikes by the other two. The first arrangement consists of wire netting projecting 4ft. or 5ft. beyond the bridge, and acts not exactly as a preventive, but more like a check, to suicide. The designer of this arrangement assumes that most people climb over the railing and drop from the bottom rails, and in that case they are caught in the net, which slopes towards the footway. From this net they may be rescued, but they may also persevere in their former resolution, and there is nothing to check them any further. In the second suggestion, a wire netting is connected to the hand rail and the suspension rods, forming a sort of awning over the footway. This arrangement appears to be satisfactory, as it makes it impossible for anybody to climb over the railing. Besides, it would not add materially to the weight of the bridge or to the surface exposed to wind pressure, and would not interfere with the general appearance of the structure. The third design shows spikes fixed to the hand rail. The spikes are about 1ft. long and curved inwards, and are likely to prove effective, besides being cheap and simple. The fourth suggestion is to have a loose wire running on the top of the hand rail supported on iron standards 1ft. high. The wire is fitted with barbed spikes at short intervals. This plan has, together with the third design, the advantage of being easily erected and cheap, and of not straining the bridge in any manner. Many more difficult problems have been satisfactorily solved, and we hope that a solution will be soon found to satisfy all persons except perhaps those tenaciously bent on suicide.

Patent Record.

Compiled from "The Official Journal of the Patent Office," by W. E. Heys, *70, Market-street, Manchester.*

APPLICATIONS FOR PATENTS.

(The names in italics within parentheses are those of Communicators of Inventions.)

ENGINEERING.

8th June, 1888.

8375. Ladd, J. H. ..... Manufacture of screws.
8377. Roe, J. T. ..... Railway vehicles.
8378. Hutchinson, H. ..... Stockless anchors.
8379. George, J. J. ..... Warehouse trucks.
8382. Briggs & Eastwood ... Carding engines.
8385. McConachy, J. ..... Ventilating apparatus.
8392. Perkins, J. ..... Lock-stitch fair-stitching machine.
8393. Anthony, J. H. ..... Breech-loading guns.
8395. Stott, J. H. ..... Warping and beaming machines (*Whitehead*).
8398. Farini, G. A. ..... Machine guns.
8400. Roberts-Horsfield and Porter..... Hydraulic presses for mining purposes.
8407. Marlor, S. ..... Self acting mules.
8417. Martignoni, J. ..... Turning and planing machine tool.
8423. Siddell, G. ..... Moving large forgings of iron or steel.
8428. Maxim, H. S. ..... Quick-firing guns.
8429. Green & Curtin..... Artificial draught in steam boiler furnaces.
8437. Molloy, P. ..... Suspended railway.
8440. Lawrence, J ..... Elevators.

9th June, 1888.

8445. Garside & Stockton... Twisting machine used in the manufacturing of felt hats.
8450. Low, R. ..... Steam boilers.
8455. Hargreaves & Inglis... Boiler furnaces.
8456. Friedrich, M. ..... Apparatus for grinding and pulverising.
8459. Corrigan, J. ..... Winding yarns on bobbins.
8460. Broadbent, H., & others Preparing and spinning cotton.
8466. Barnett, C. ..... Hydro-compressed air power.
8467. Rothwell & Rothwell Picking motion of looms.
8469. Eyre, W. ..... Forged hollow weldless shells.
8483. Mannesmann, M. ..... Toothed gearing wheels.
8484. Mannesmann, M. ..... Universal joint for coupling revolving shafts.
8485. Mannesmann, R. ..... Fire proof columns.
8487. Mannesmann, M. ..... Tubular shafts.
8494. Davies, E. J. V. ..... Manufacture of paper.

11th June, 1888.

8511. Burdon & Clark..... Steel castings.
8520. Hunt & Crockford ... Marine governor.
8521. Coulter, J. ..... Stone dressing machinery.
8523. Crosland, W. ..... Automatic machine to press books.
8524. Lynde, F. C. ..... Water gauges.
8526. Stockwell & Widdowson..... Securing rails in railway chairs.
8531. Boult, A. J. ..... Steam pumps (*Northey*).
8534. Boult, A. J. ..... Rotary engines (*Avis*).
8537. Hodder & Swain..... Manufacture of mats.
8538. Biggerstaff, J. ..... Nosing motion for mules.
8541. Kiddier, H. ..... Knitting machines.
8542. Anderson, G. ..... Raising girders.
8547. Wheatley, W. H. ..... Wheels for waggons (*Hall*).
8549. Nagel & Linnenbrügge Stone crushers.
8550. Lechner, E. ..... Purifying feed water.
8553. Boluss, A. R. ..... Air brakes.
8565. Yates, J. ..... Starter for vehicles.
8568. Stark, D. ..... Heating & purifying feed water.
8571. Pitt, S. ..... Supplying water to boilers (*Kieley*).

12th June, 1888.

8577. Clegg, T. ..... Bed for cloth cutting or finishing machines.
8583. Landye, J. ..... Steam chests and slide valves.
8589. Withy & Sivewright... Drainage wells in connection with water ballast tanks in vessels.
8593. Bosley & Dickson ..... Safety valve.
8601. Newington, A. S. L. ... Apparatus for raising water.
8602. Hattersley & Hall ... Friction clutch and brake mechanisms.
8614. Day, C. A. ..... Machinery for making wire nails (*Morgan*).
8615. Cochrane, R. ..... Weaving chenille.
8619. Dempsey, C. W. ..... Traction and brake apparatus.
8620. Butler, E. ..... Hydrocarbon motors.
8628. Oliphant, W. ..... Apparatus for feed water heating and filtering.
8629. Bartlett, J. E. T. ..... Blades of propeller wheels.
8633. Imray, O. ..... Feed water regulator (*Cook and Thoens*).
8635. Vojáček, L. ..... Cutting rails and girders.
8638. Lake, H. H. ..... Sewing machines (*Peerless Button Hole Attachment Co.*)
8642. Moraes, A. C. da C. ... Weaving ribands. (Date applied for under Section 103 of the Patents Act, 1883, February 24, 1888).

13th June, 1888.

8653. Banks, L. F. ..... Breech-loading fire arms.
8656. Friedrich, M. ..... Friction clutches.
8665. Hyde, G. T. ..... Swaging metallic shapes (*Price*).
8667. Stark, J. ..... Hydraulic apparatus for starting tramway cars.
8682. Picking & Hopkins..... Wind engines or motors.
8686. Cannon, F. W. ..... Steam engines.
8688. Ainley & Oakes ..... Drilling machines.
8692. Taylor & Taylor ..... Driving sewing machines.
8696. Pinkney, C. W. ..... Gas engines.

14th June, 1888.

8703. Shaw, J. F. ..... Motive power engines.
8712. McAdam, J. ..... Tools for slotting machines.
8713. Schmidt, W. ..... Steam generators.
8714. Offermann & Ziegler. Combing machines.
8719. Whiteley, J. B. ..... Sectional warping machines.
8725. Parker & Turner ..... Boiler furnaces.
8729. Ferriday, J. ..... Hydraulic wedges employed in the falling of coal.
8730. Willcocks, R. T. ..... Paper making machines.
8734. Hardwicke, J. B. ..... Application of anti-friction rollers to thrust bearings.
8744. Alloo, L. J., & others... Railway signalling.

ELECTRICITY.

12437A. Crompton & Swinburne ..... Electrical measuring instruments. (This Application having been originally included in No. 12437, dated 14th September, 1887, takes, under Patents Rule 23, that date.)

8th June, 1888.

8401. Clifton & Robinson ... Electric batteries.

9th June, 1888.

8457. Mellett, L. ..... Telephones.
8503. Ducretet, E. ..... Magneto-electric exploders.

11th June, 1888.

8525. Rawson & Jolin ..... Electric bells.

12th June, 1888.

8596. Johnson, J. Y. ..... Automatic telegraphy (*Mallett*).
8637. Parcelle, A. L. ..... Electric clocks.

13th June, 1888.

8657. Barcroft, H. ..... Dynamo-electric machines.
8700. Renard, L. M. J. C. C... Electric batteries.

14th June, 1888.

8724. Snelgrove, W. ..... Electrical switch machines.

CHEMISTRY.

8th June, 1888.

8410. Groth, L. A. ..... Purifying metals (*Pellegrin*).
8427. Guild, J. E. ..... Extraction of the precious metals (*Galbraith*).

9th June, 1888.

8496. Lea & Hammond..... Electro coating metals with zinc.

12th June, 1888.

8597. Hanson, J. ..... Generating sulphurous acid gas.
8604. Stitt, C. A. ..... Soap.

14th June, 1888.

8738. Lisle, E. A. de..... Vegetable black for decolourising.
8740. Nevill, W. H. ..... Soap.
8746. Brin, L. Q. ..... Plating with aluminium.
8747. Brin, L. Q. ..... Aluminium bronze and other alloys of aluminium.

MISCELLANEOUS.

8th June, 1888.

8380. Sarjeant, E. ..... Oil lamps.
8381. Lynam, P. J. ..... Range finders.
8383. James & James ..... Horseshoes.
8384. Wooldridge, H. ..... Horseshoes.
8388. Carmichael, D. C. ..... Steering cycles.
8396. Boothroyd, I. W., & ors. Velocipedes.
8404. Emsley, J. W. ..... Cycles.
8406. Herbert, C. ..... Velocipedes.
8422. Baker & Fowler ..... Valves and taps.
8424. Betjemann, S. ..... Copying presses.
8425. Leechman, G. D. ..... Velocipedes.
8426. Plom, L. ..... Blasting cartridges.
8430. Earle, E. J. V. ..... Manufacture of boots.
8431. Hartley & Rose..... Valves.
8434. Boult, A. J. ..... Manufacture of water proof linen (*Warschauer*).
8436. Winsor, G. F. ..... Manufacture of rugs.
8441. Bellis & Dadd..... Lubricator.

9th June, 1888.

8453. Brining, T. ..... Manufacture of boots.
8454. Coleberd, G. E. ..... Cultivator and pulveriser.
8462. Chippindall, J. ..... Velocipedes.
8468. Hutchinson, W. N..... Little friction with the "Jones—circuitously—travelling piston."
8470. Young, C. ..... Mortise latches.
8472. Whibley, E. ..... Guide fence to machines.
8473. Watkins, J. L. ..... Velocipedes.
8479. Gagné, R. ..... Flexible tubes for fluids under pressure.
8480. Galley, J. G. ..... Destroying refuse.
8486. Stringer, W. ..... Reciprocating sieves.
8491. Price, J. ..... Expelling liquid from sewage.
8498. Clegg, W. W. ..... Bicycles.
8501. Keen & Alleyne..... Caulking the seams of steam boilers.
8504. Smith, C. ..... Projectiles (*Margary*).

11th June, 1888.

8505. Grätz, M. ..... Extinguishers for lamps.
8507. Bell, G. ..... Malleable cast iron nails.
8512. Southon, S. J., & others Valve.
8515. Malvern, T. ..... Gulley trap.
8522. Fericka & Eggimann... Clarifying fermented liquids.
8528. Swingler & Airey..... Tube expanding plyer.
8530. Holliday, T. ..... Fabrics dyed black, composed partly of animal and partly of vegetable fibres.
8532. Thompson, W. P. ..... Gas lamps (*Herzfeld*).
8539. Baxendale, L., & ors.... Lead wire and piping.
8540. Smith, J. ..... Adjusting the length of muzzle and check straps for looms.
8543. Leechman, G. D. ..... Velocipedes.
8546. Wheatley, W. H. ..... Joints for metal vessels (*Barrath and Knecht*).
8551. Westwood & Wright... Lids or covers of gas retorts and ovens.
8558. Haggenmacher, C..... Sifting granular material.
8559. The Gas Patents Syndicate ..... Manufacture of gas (*Archer*).
8560. The Gas Patents Syndicate ..... Fuel gas burners (*Archer*).
8561. The Gas Patents Syndicate ..... Kilns for firing bricks (*Archer*).
8562. Osgerby & Lea ..... Chimney tops.
8572. Hayes, W. R. ..... Ventilation of ships.
8574. Wise, W. L. ..... Centrifugal cream separators (*Jonsson*).

12th June, 1888.

8576. Bradshaw, J. ..... Fibrous substances.
8580. Lucas & Bennett ..... Lamp burners.
8582. Doleman, T. ..... Easing the setting on of straps for mules.
8584. Farini, G. A. ..... Cartridges.
8591. Packer, W. N., & others Belt fastener.
8592. Triffitt, W. ..... Gas cocks.
8603. Burkin, B. ..... Laying fog signals on railways.
8605. Zimmerman Refrigerator Company ..... Refrigerators.
8624. Petersen, H. ..... Centrifugal separators.
8625. Michaelis, M. ..... Horseshoes.
8627. Oliphant, W. ..... Liquid purification.
8639. Gigon, A. ..... Watches and clocks.
8640. Sugg, W. T. ..... Gas regulators.
8641. The Lezant Syndicate Manufacture of manures from basic slags.
8643. Mumford & Moodie ... Separating dust.
8649. Walker, J. ..... Valve taps.
8650. Walker, J. ..... Stop cocks.

13th June, 1888.

8651. Schönheer-Schöner, T. Locks.
8658. Harris & Williams ... Coating tin plates.
8660. Lynam, P. J. ..... Range finders.
8661. Manwood & Manwood Cans for containing slivers.
8662. Jackson, J. W. ..... Vessels for measuring fluids.
8663. Johnston, J. ..... Apparatus for heating & drying.
8664. Beck & Bleckley ..... Grate bars.
8666. Lewis, A. E. ..... Cycles.
8668. Settle, M. ..... Cartridges for blasting in mines.
8689. Lyddon, C. ..... Horseshoes.
8693. Baker, C. ..... Cement.
8695. Defries & Feeny ..... Lamps.
8697. Sandeman, J. ..... Mariners' compasses.
8701. Gascoigne, A. ..... Lubricating the axles of vehicles.

14th June, 1888.

8704. Harrison, H. C. ..... Fire escape.
8708. Baxter, L. ..... Connecting links for chains.
8710. Thompson, W. P. ..... Ventilating apparatus (*Gourdan-Fromentel*).
8715. Fawcett, T. C. ..... Manufacture of briquettes.
8716. Manger & Blyton ..... Fog signalling apparatus.
8717. Snell, S. ..... Hurricane lamps.
8723. Ashwin, M. C. ..... Manufacture of bricks.
8727. Plested, W. E. ..... Sharpening chisels and plane irons.
8728. Barry, J. H. ..... Purification of sewage.
8742. Cannot, G. A. ..... Utilising peat fibre (*Béraud*).
8745. Teideman, G. ..... Liquid meters.
8748. Dambois, L. ..... Locks.

COMPLETE SPECIFICATIONS ACCEPTED.

ABSTRACTS OF BRITISH PATENT SPECIFICATIONS.

Compiled from the Published Specifications by W. E. Heys, 70, *Market-street, Manchester.*

ENGINEERING.

Rotary Engine.—*J. Selwig, Braunschweig, Germany.*—The two accompanying figures represent two sections taken at right angles to each other. The engine consists of three main parts—the crown wheel A, the pinion wheel B, and the casing C. The teeth D of the wheel A are cast in one piece with the cylindrical disc S, which is attached to the driving shaft O. The wheel B turns on the axis P, which forms part of the outer

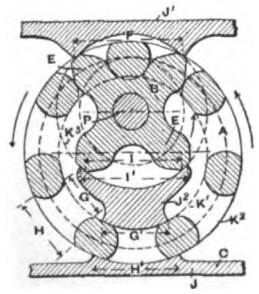

Fig 1.

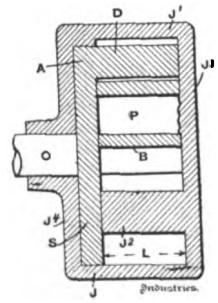

Fig. 2.

casing. The part J^2 of the casing forms a prismatic projection penetrating from the front side part J^3 to the inside of the wheel A. When a liquid under pressure is present at the left hand side of Fig. 1, the wheel B is caused to turn in the direction of the arrow, carrying with it the wheel A; motion is thus transmitted to the shaft O. The engine can be used for either liquids or gases, and as a pump or blower. Six claims are made for this engine, and for an adaptation.—No. 3801. March 12th, 1888. 8*d.*

Combing Machines.—*I. Holden, Keighley, Yorkshire.*—The drawing-off rollers which are employed for drawing the fibres from the travelling combs have hitherto been pressed together at their ends by means of springs. It has been found that this end pressure tends to arch the rollers, so that their grip is impaired at the centre. The present inventor supplements the use of the two ordinary drawing-off rollers by the employment of additional rollers for the purpose of supporting the rigidity of the other rollers. In applying this method to a square motion comb circle, the two additional fluted rollers have each an endless leather apron working round it; one of them works below and against the lower drawing-off roller, and the other over and against the upper drawing-off roller. The under additional roller may run in either fixed or adjustable spring bearings, and the upper one is adjustably borne by spring pressure to its drawing-off roller. One claim is made for the employment of these additional rollers for the purpose described.—No. 9989. July 16th, 1887. 11*d.*

Gas Engines.—*C. G. Beechy, Liverpool.*—This invention relates to certain improvements in the gas engine which was described in Patent No. 3199 of 1885, granted to the same patentee. One of the improvements consists in arranging the compression and working cylinders in such a manner that the piston of the compression cylinder shall complete its stroke before the piston of the working cylinder has completed its instroke. Plenty of time is thus allowed for the discharge of the gases before the communication between the two cylinders is closed. This is effected, as shown in Fig. 1, by inclining the compression

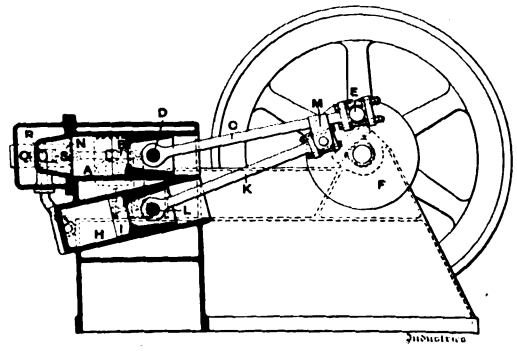

Fig. 1.

cylinder H at an angle with the working cylinder A. The connecting rod is coupled by the piece M to the rod C. Another part of the improvement consists in the employment of a single slide valve N, which serves the triple purpose of a valve for the admission of the air and gas to the compression cylinder, of a valve for the passage of the air and gas from the compression cylinder to the power cylinder, and as a communication for firing the charge. The port P effects the communication alternately between the air and gas supply pipe Q and the port R leading to the compression cylinder H, and between the port R and the port S of the power cylinder A. The firing hole is shown at T, and the igniting tube at U. The exhaust port V is situated at the side of the cylinder A, and near the middle of its length, and the exhaust valve W is operated through the intermediate lever X by the same eccentric that works the slide valve N. In the outward stroke of the two pistons, the compression piston I draws a charge of air and gas into the cylinder H through the port P, the slide valve being then in the position

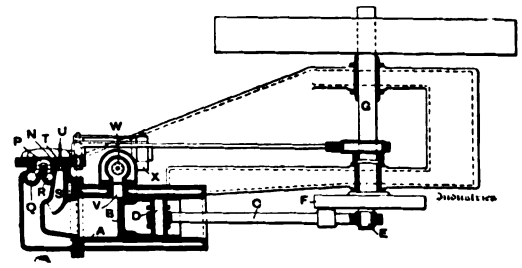

Fig. 2.

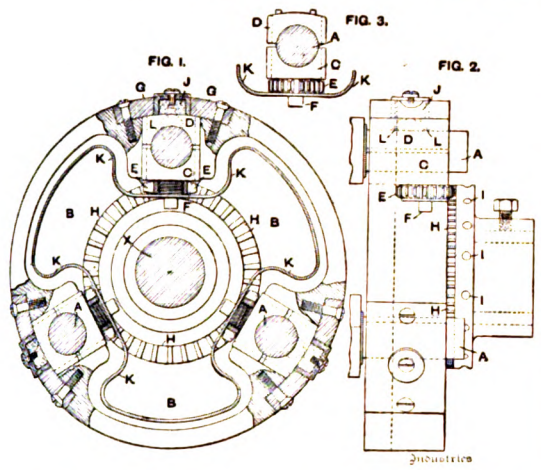
shown in the figures. In the return stroke this charge is forced through the port P into the charge chamber of A, the port P being then in communication with the ports R and S. During this time the exhaust port V is open until the piston B passes over it; after which the compression of the charge takes place in the charge chamber, and the charge is fired. Owing to the angle between the two cylinders, the piston I has a slight lead, and completes its instroke before B; the combustible charge is therefore forced into the power cylinder before the piston completes its instroke. As it is not required to fire the charge before the power piston has completed its instroke, there is time for the slide valve to close the communication between the two cylinders before the firing hole T comes into communication between the port S and the igniting tube U; a lap of $\frac{3}{32}$in. is obtained, and any liability of the fire passing into the port P is prevented. Three claims are made for the inclination of the two cylinders to each other, and for the slide valve arrangement as described.—No. 8818. June 18th, 1887. 8*d.*

Steam Boilers.—*W. Ambler & W. O. Blackburn, Bradford.*—The object of this invention is to promote a greater circulation of the water in the boiler and to increase its heating surface. The main flue is constructed in sections of a corrugated form, which are united by sections of a plain cylindrical form. An auxiliary boiler tube is placed within this flue rather nearer to the top than the bottom; it is made up of sections in a similar manner to the flue, and is connected by short tubes to the boiler above and below the main flue. By this arrangement the flames which pass along the top of the flue are forced downwards and encircle the auxiliary tube, and their heat is therefore more fully utilised. One claim is made for the formation of the tube and flue, and for the disposition of the one inside the other.—No. 8172. June 7th, 1887. 8*d.*



Spherical Engines.—*R. H. Heenan, Manchester.*—Improvements are here introduced into the construction of the spherical engines described in T. Bower's Patent No. 3953 of 1879, and Heenan & Froude's Patent No. 13102 of 1884. In these engines there is a librating and revolving piston, which forms the middle member of a universal joint connecting two inclined shafts, which have semi-circular blades jointed to the piston at right angles to each other. According to the present invention, the jointings of the blades to the piston are arranged at points nearer to the centre of the piston than formerly; the piston is thus permitted to have an uninterrupted periphery, which is fitted with a spring packing ring. The joints of the blades and the piston are provided with bushes and packings, and oil holes are drilled obliquely through the blades and their bosses to a central oil passage in the shafts. Three claims are made.—No. 16420. November 29th, 1887. 8*d.*

Digitized by Google

FRICTION CLUTCH.—*O. Reynolds, Manchester.*—In the improved form of clutch, one friction disc is mounted on a feather key on the shaft to which power is to be transmitted, and a second friction disc is loose on the shaft. The first disc is controlled by a clutch lever, and one end of a spiral spring or flexible band of metal is secured to the boss of the second disc. The flexible band of metal is coiled round a sleeve fixed on the shaft, and its other end is secured to the boss of a bevel wheel which is mounted loosely on the shaft, and which receives motion from a bevel wheel on another shaft. When the first disc is moved into contact with the second disc driven by the spiral spring from the bevel wheel, the resistance caused by the frictional contact between the two discs binds the spiral spring to the surface of the sleeve, and so rotates the shaft. When the first disc is moved out of contact with the second disc, the coil unbinds itself from the sleeve and so releases the shaft. Three claims are made.—No. 9603. July 7th, 1887. 8*d.*

MACHINE FOR MAKING DIES.—*H. H. Lake, London.* (*G. McKay, Boston, U.S.A.*)—This machine is designed for the purpose of automatically grinding and grooving the bevelled faces of the dies which are used in the manufacture of cut nails. The machine consists of a grinding wheel and a scoring wheel, which are composed of emery and attached to the same rotating spindle. The cup wheel, which is used in grinding the bevelled ends of the dies, acts on the dies while they are held in a groove in a suitable carriage; the bottom of the groove is inclined in the right way so as to give the end of the die the desired bevel, and the carriage is automatically reciprocated by special mechanism. The scoring wheel at the opposite end of the shaft is more or less rounded at its acting edge, according to the groove which is to be cut in the die. In order to keep the edge of the scoring wheel in its established curve, the machine is provided with a wheel-shaping tool, composed of a diamond confined in a holder, which is mounted upon an adjustable pivoted arm. This arm is made adjustable in a direction perpendicular to the axis of the wheel to be ground, and also in the arc of a circle at right angle to the axis of the scoring wheel. The holder for the diamond is longitudinally adjustable in the arm. Ten claims are made for the various details of this machine.—No. 5325. April 10th, 1888. 8*d.*

NAP RAISING MACHINES.—*J. Y. Johnson, London.* (*G. M. Bauche and H. A. Bauche, Paris.*)—Figs. 1 and 2 show a front and side view of a set of three workers or nap raisers, and Fig. 3 is a detached view of the bearings of a worker. The axis A of each of the workers is mounted in bearings C D; C is capable of sliding in guides in the carrier B. According to the degree of pressure of the spring K on the movable portion C, the freedom of the shaft A to rotate will be regulated; and as the rotation of the shaft is effected by the contact of the workers with the

material, the action of the workers on the material will be varied by the degree of elasticity of the spring. To regulate its elasticity the movable part D is provided with a stem F, upon which is screwed the pinion E gearing with the wheel H. By rotating the wheel H the pinion E will be screwed up or down, and the spring will press the movable part D against the axles A with greater or less power. Each of the parts C of the bearing is held in position by a covering plate G, which is screwed upon the rim of the carrier B, and in this plate there is a chamber J for the reception of lubricating matter. Five claims are made for mounting the workers in flexible or yielding bearings, so arranged as to be capable of being adjusted to vary the pressure of the workers on the material operated on.—No. 4102. March 16th, 1888. 8*d.*

STEAM ENGINES.—*C. H. Benton, London.*—This improvement is intended to obviate the wear and tear of the reciprocating parts and their connections, consequent upon the strains in these parts when the crank passes the dead points. Two systems of reciprocating parts are attached to the same crank, one system communicating the impulse of the steam in one direction, and the other in the contrary direction. The systems work together as a single double-acting piston as far as the distribution of the steam is concerned; but they have a slight relative movement, and consequently, as far as the strains are concerned, they form a double system. The piston head is made in two parts; to one of these parts is attached a hollow piston rod, which is connected to two crank pins by two connecting rods on each side of the hollow rod; to the other part of the piston is attached a piston rod which is capable of a slight longitudinal movement through the hollow rod. A connecting rod communicates motion from the inner piston rod to a crank placed between the two other cranks on the driving shaft. Each part of the double piston is exposed to the pressure of steam in one direction only, and the strains caused by this pressure are always in the same direction, and not alternately reversed, as is usual in ordinary engines. In order to keep the strains in the same direction at the end of the stroke the inventor employs auxiliary cylinders, whose pistons are attached to the two sets of reciprocating parts. These pistons compress some of the steam upon their return stroke, and thus counterbalance the energy of motion of the moving parts. To facilitate the starting of the engine, a stop cock is placed in the auxiliary cylinders, so as to allow the compressed fluid to escape during the first few strokes, or, if permanent pressure is used, a valve is arranged for the purpose of removing the pressure during the first few strokes. Five claims are made for these double systems of reciprocating parts as described.—No. 7729. May 27th, 1887. 8*d.*

LATHES.—*J. Barrow, Johnstone, Renfrew.*—By this invention an improvement is introduced into the construction of lathes which are used for turning long shafts. Hitherto a sliding stay has been employed which is separate from the ordinary slide rests carrying the cutting tools, or the slide rests have had to be removed from the saddle of the lathe and a special construction of apparatus substituted, in which the slide rests and stay are more or less self contained. The present invention enables the ordinary rests of a duplex lathe to be retained and utilised for the purpose of sliding with a self contained stay; a holding piece formed to contain the stay is attached to the front or back rest, and to the other rest a similar holding piece is attached, which carries another slide rest and turning tool within itself. Whatever may be the diameter of the stay it can be firmly fixed between the back and front rests by using the screws which actuate the bottom rests upon the saddle, until the stay is rigid and concentric with the shaft to be turned; the ordinary back and front rests as well as the finishing rest are close to the work, and the tools are capable of adjustment without disturbing the rigidity of any of the parts. One claim is made.—No. 9344. July 1st, 1887. 11*d.*

GAS ENGINES.—*H. Lea, Birmingham.*—Two improvements are here introduced for facilitating the starting of the engine. The first improvement is intended to do away with the necessity of the fly wheel being rotated by hand. For this purpose a hollow circular casing is fitted loosely upon the projecting end of the crank shaft, and within it is a ratchet wheel, which is keyed securely on the shaft; the hollow casing also contains one or more spring pawls engaging with the teeth of the ratchet, and a series of holes, preferably four, are formed in the rim of the casing, into any one of which a handspike can be inserted. When it is required to start the engine, the gas is first turned on and the slide light ignited in the usual way, and the lever, having been placed in one of the holes in the rim of the casing, is worked up and down like a pump handle, and the crank thus turned. When the engine has attained some speed, the crank shaft cannot turn the lever, as the connection between them is only the ratchet and pawl mechanism. Two other modifications are described in the specification for effecting the same object. The second part of this invention relates to the movement of the exhaust cam from the non-compression position at starting to the compression position after the engine has attained a certain speed. To obviate the necessity of completing this operation by hand, the inventor attaches a bent arm to the upper end of the exhaust valve lever. To the inner face of the bent arm is pivoted a short lever pointing upwards, which can be moved to and fro through a small arc by means of a knob upon its upper end. From the inner face of the movable lever project two pins, at such a distance apart as to embrace the exhaust roller, and the motion of the lever is limited by two stops fixed to the bent arm. When the lever is moved to and fro by hand, which can be safely done while the engine is working at full speed, the roller is moved to and fro upon its stud in a direction parallel to the axis of the stud, and can thus be immediately placed in either of the required positions. The knob is sufficiently heavy to maintain the lever in either position, so that the usual pin can be dispensed with. Two claims are made.—No. 13436. October 4th, 1887. 8*d.*

ELECTRICITY.

VOLTMETERS.—*W. E. Ayrton & J. Perry, London.*—One or more short straight fine parallel wires of conducting or semi-conducting material are fastened at both ends to supports which are fixed inside a short horizontal tube. The wires are attached at their middles by means of a stirrup and fine wire to one end of a magnifying spring, as described in Patent No. 2156 of 1883. The other end of the spring is fixed so that its axis is at right angles to that of the wires. On passing a current through the wires they stretch slightly on account of the heat generated, and a pointer attached to the end of the magnifying spring is rotated. The instrument may be also adapted for use as an ammeter by attaching a shunt to the wires; the shunt consists of a metallic rod or strip which is longer than the wires, and so does not heat. Three claims are made.—No. 7802. May 28th, 1887. 8*d.*

REGISTERING WATT-METER.—*H. H. Leigh, London.* (*J. L. Clerc, Paris.*)—The indications of an ammeter or watt-meter are transmitted intermittently to a quadrant or cam through the agency of a coil which is excited by a special circuit by means of a clock. When an ammeter is used, a current is passed through a coil whose iron core depends from a cord passing round a pulley; on the axis of the pulley is mounted a triangular plate or equivalent cam, the outer edge of which is provided with a scale. The core of a second coil is suspended over the rim of another pulley, and is balanced by a counterpoise; a ratchet wheel slides over a prolongation of the axis of this pulley, and a pawl on the pulley engages with the teeth of the ratchet. When the current flows through the second coil its core is lifted; when the counterpoise drops, and comes in contact with the outer edge of the triangular plate above mentioned; the pulley over which the cord passes is rotated, and the pawl slips over the teeth of the ratchet wheel. The second coil is wound with fine wire, and is excited by a special circuit controlled by a rheostat which is actuated by a clock. This clock at periodic intervals will move the arm of the rheostat, and will transmit through the coil a current at first gradually increasing, and afterwards decreasing by means of the resistance of the rheostat. When the current decreases, the iron core of the second magnet slowly drops, and by means of the pawl and ratchet its motion is communicated to a train of wheels. Instead of employing an ammeter, the inventor sometimes makes use of a watt-meter. The instrument is arranged vertically, and the fine wire coil is placed within the other coil, which is wound with thick wire. A spiral spring counterbalances the reciprocal action of these two coils, and a pair of leads conduct the current into and out of the coils. The fine wound coil is suspended, and carries a vertical rod which supports a horizontal rod, and one end of the horizontal rod is furnished with a balanced pawl. The vertical rod also carries at its lower extremity a horizontal rod, to which are fixed two arc-shaped cores each at the same distance from the rod. These cores are actuated by fine wound coils whose cavities are shaped to correspond to the cores. The coils are excited in the same manner as the second coils were before. As the current gradually increases and decreases in proportion to the motion of the arm of the rheostat, the pair of arc-shaped cores slowly move the fine wound coil of the watt-meter, which is first let down to zero and afterwards slowly regains its equilibrium. The balanced pawl engages with a gear wheel, over which it slides when the watt-meter leaves zero, and by means of the arc-shaped cores rotates the wheel when the watt-meter returns to zero. Two claims are made for these two arrangements.—No. 3303. March 3rd, 1888. 8*d.*

MAGNETO-ELECTRIC MACHINES.—*W. Gillett & G. Haseltine, New York.*—The magneto-electric machine here described is intended for generating currents for ringing bells and other similar purposes. Fig. 1 shows a plan and Fig. 2 a vertical central section of the machine. A is a frame which forms an

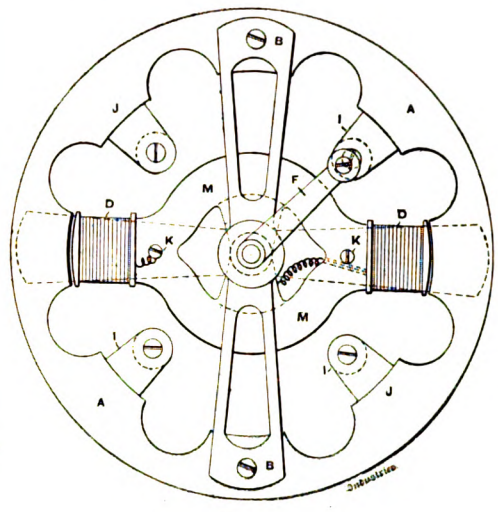


FIG. 1.

armature, and B are cross bars which are attached by means of screws to the frame; the lugs I secure the generator to its base. The magnet C carries coils D of insulated wire, which are fastened together by the screws K. The trunnions E from the centre to the outside magnet pass through the cross bars B, and the handle F attached to the outer trunnion serves to revolve the magnet C and coils D. One end of the wire G passes from

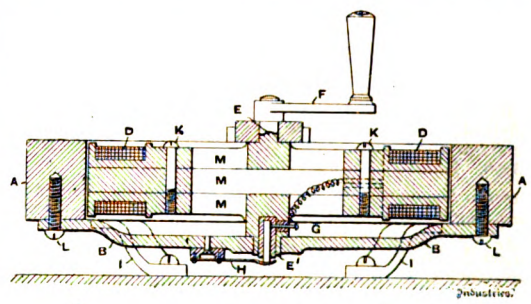

FIG. 2.

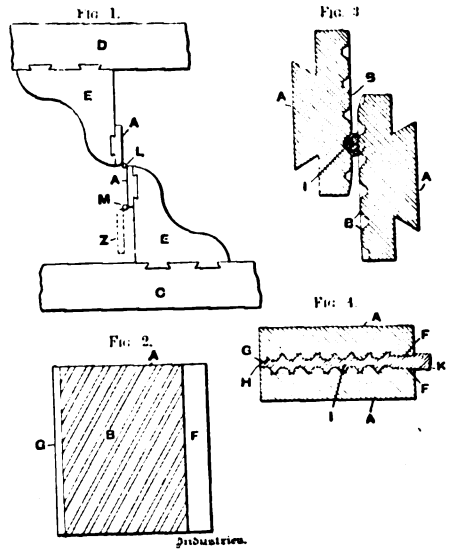
the coils D through the main trunnion, and makes connection with the spring H, which is insulated from and attached to the cross bar B. The handle F is turned to operate the generator; the permanent magnets C and the coils D are revolved, passing the segmental portions J of the frame A. As the coils approach these projecting portions the magnetism is diminished, and as they recede the magnetism is augmented, and a current is thus produced in the coils. Three claims are made for the projections J of the armature and for the combination of the parts B C D G and H.—No. 4929. April 3rd, 1888. 6*d.*



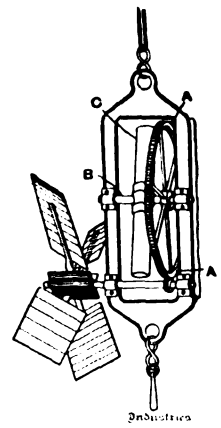
DYNAMOS.—*E. Jones, Leeds.*—The present invention relates to a method of forming the brushes and holders, with the object of insuring a steady pressure between the brushes and commutator, and of preventing the wear of the commutator incident on the friction of the brushes. The brush is formed of a bundle of fine copper wires; this bundle is first dipped in a suitable lubricant, and is then inserted in a metal tube of thin brass, and soldered to one end of it. The tube and its contents are submitted to pressure in a mould, by which means the tube is flattened out, and a number of serrations are formed on its under side in order to receive the edge of a clip. The brush holder consists of a two-armed bracket, which has a slot in each arm for the purpose of receiving the brush. A spring which is secured to the bracket carries the clip before mentioned. By means of this spring connection the brush is kept in contact with the commutator at a regular pressure. The bearing end of the brush is bevelled off to accommodate itself to the commutator, and as the brush end becomes warm the lubricant is gradually drawn down to the point of contact. The inventor makes two claims for the brushes and holders respectively.—No. 9011. June 24th, 1887. 8*d.*

Digitized by Google

MISCELLANEOUS.

ARTIFICIAL FUEL.—*J. Swallow & N. Proctor, Leeds.*—In order to manufacture one ton of the fuel, the inventors take 5lb. of sugar, 5lb. of flour, 5lb. of resin, 40lb. of pitch, and 1lb. of common salt, and mix these ingredients with the requisite weight of coal dust or the like to make up the ton. The whole is mixed together and moistened with water. The mass, being then in a plastic state, is passed through an ordinary brick machine, from whence it issues in compact blocks. Instead of mixing water with the combination of materials, the mass may be heated, and the resin and the pitch then form the cohesive medium. One claim is made for the constitution of this artificial fuel.—No. 5689. April 17th, 1888. 4*d.*

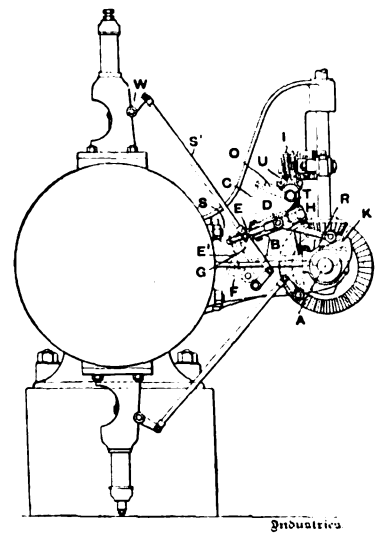
DIES FOR MANUFACTURING TWIST DRILLS.—*A. Laundry, Coté St. Paul, Montreal, and H. H. Warren, Massena, New York.*—This invention relates to the construction and arrangement of dies which are employed in the manufacture of twist drills. The dies are made with diagonal ribs, and are set face to face, so that when one is moved parallel to the other, a round bar rolled between has the required helical twisted form imparted to it. Fig. 1 represents the dies arranged in connection with an ordinary power press; Fig. 2 is a front elevation on an enlarged scale of one of the dies; and Figs. 3 and 4 are sections of the pair of dies. A A are the two dies, each made with diagonal parallel ridges B of an approximately semi-cylindrical shape. One die



moves over the other in the vertical direction in Fig. 2. F and G are marginal surfaces without ridges, and they are made slightly inclined, in order to give the neck and the point of the twist drill a conical form. As shown in the figures, the faces of the dies are for the greater part of the depth parallel to one another; but the lower part of the one and the upper part of the other slope gently back, so that the bar to be acted on can be freely entered as at L in Fig. 1, and taken out from between the dies at M. The brackets E are attached to the bed C and follower D of the press. The inventors claim, in the manufacture of twist drills, the use of a pair of dies, each having diagonal parallel ridges arranged face to face, so as to roll between them a round bar and to impress it with a helical twist, as described.—No. 3096. February 29th, 1888. 6*d.*

DRIVING SPINDLES.—*L. Binns, Philadelphia.*—A single band is here employed for driving a pair of spindles on the opposite side of a spinning and twisting frame. The drum is placed between the two rows of spindles at right angles to them. The band passes from the whirl of one of the spindles across and over the drum to the whirl of the opposite spindle; having passed round this whirl, the band goes round the drum and back to the whirl of the last named spindle, round it, and across and under the drum to the whirl of the first named spindle; it then goes round this whirl, and round the drum, and back to the point from which it started. By this arrangement a firmer hold is obtained on the spindles with an increased length of band; the total length of band, however, is much less than is ordinarily used when the two spindles are driven by separate bands. Two claims are made.—No. 5335. April 10th, 1888. 6*d.*

LIME AND CEMENT KILNS.—*N. R. Foster, Uxbridge, Middlesex.*—The burning and drying chambers are so constructed that the heated gases in passing from the kiln to the chimney shall be made to pass alternately over the surface and underneath the slurry in the drying chamber, and thereby to utilise to the greatest extent possible the heat of the gases from the burning chamber. The kiln pans are oblong in form, with rounded angles; their internal sides diverge upwards, and are completed by an arched crown. The usual low arched wickets and high fire bars are dispensed with, much higher wickets are employed, and the fire bars are placed at a short distance from the floor. By this arrangement the kilns can be loaded and discharged more readily, and the draught is increased. The drying chambers are attached to the kilns in pairs, each pair being divided by means of an inner wall, in which are a number of arched openings. The drying chambers are closed by arches, whose upper sides form the drying floor for a chamber above. The floor of the lowest chamber is flat, and is composed of tiles which are built so as to allow the current of heated gases to enter underneath them. By this arrangement the furnace gases can approach the slurry alternately over and under it; and as the drying chambers are arranged in pairs, their floors are less arched, and the layer of slurry is consequently of more uniform depth. Four claims are made for this construction of kilns and drying chambers.—No. 7708. May 27th, 1887. 11*d.*



GERMAN PATENT ABSTRACTS.

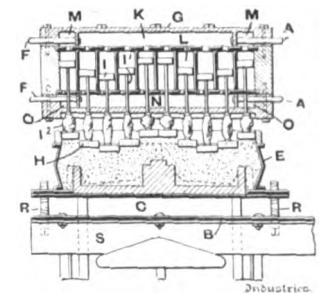
WATER METER.—*K. T. Boeckler, Munich.*—Vanes are attached to a spindle provided with a cog wheel which gears with the wheel A, to the spindle B of which is secured a tube C. C contains a ball which comes in contact with the ends of C when

A is revolved, thereby imparting a jerking motion to the cord on which the apparatus is suspended. The water flowing through a vessel actuates the vanes which revolve A. The jerking motion in the cord actuates a counting apparatus, which thus records the revolutions of A.—No. 42800. August 21st, 1887.

VALVE GEAR.—*K. Seiffert, Leipsic.*—In this valve gear the admission valve is actuated by a cam K keyed to the shaft A, which rotates in the direction of the arrow. The cam K actuates the bent lever H, which is fitted with a roller R, and H oscillates round the pivot D. This oscillating motion is transmitted by means of the connection G to the rod S, which actuates the valve by means of the bent lever W. In order to obtain a

variable admission the pivot D of the lever H is secured to a slide T, which slides in the guide B. The slide T is influenced by the governor, which actuates a rack into which the pinion gears. To the shaft of this pinion is keyed the worm I which gears with the worm wheel segment U. The motion of U is communicated by the levers C O F E' to the slide T. The alteration in the position of T also causes the points D and E to change their position. If D moves towards E the roller R gets nearer to the shaft A, and engages for a longer time with the cam K, thereby increasing the period of admission. A movement of D in the opposite direction has the opposite result.—No. 43016. August 20th, 1887.

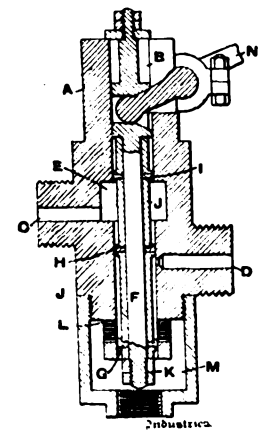
UNITED STATES PATENT ABSTRACTS.



A NEW WARP FOR PATTERN MAKING.—*C. H. Landenberger, Philadelphia.*—Short warps for pattern weaving are formed in a broad loom by interweaving the weft threads carried by the shuttles with warps placed in groups on opposite sides of the loom; these warps are adapted to serve as head bands, and other warps are woven at intermediate intervals to serve as lease threads. The weft threads thus interwoven with the head bands constitute short warp. When one such warp or section has thus been produced, it is wound upon a warp beam, and the ends of its threads are joined to those of the threads of other sections formed in a similar manner of either the same or different designs. Three claims are made.—No. 383182, dated 22nd May, 1888.

COTTON GIN.—*D. B. Haselton, Charleston, North Carolina.*—The gin has two hoppers, between which revolves a cylinder, and inside the cylinder is a series of frames provided with teeth. The teeth are protruded while they are in the interior of the cylinder, then are gradually withdrawn while passing the seed bars, and finally withdrawn fully in order to drop the cotton. The pivoted frames are connected by rods, which at each end extend into cam grooves in plates at the ends of the gin; the cams effect the change of position of the teeth in the manner desired. Five claims are made.—No. 383223, dated 22nd May, 1888.

NUT LOCK.—*L. J. Benton, Alpine, New York.*—This arrangement for locking nuts is intended to be used in combination with two similar bolts and nuts. A spring bar has its ends coiled round on different sides of itself, and these coils are placed round the threads of the screws, the bar extending diagonally between the two bolts. The upper sides of the loops are serrated, and they gear with similarly serrated washers placed underneath the nuts. There is also a projection from the washers which lock with the nuts. After the nuts have been screwed round and fixed, the serrations in the loops and washers effectually prevent any slipping. Two claims are made.—No. 382789, dated 15th May, 1888.

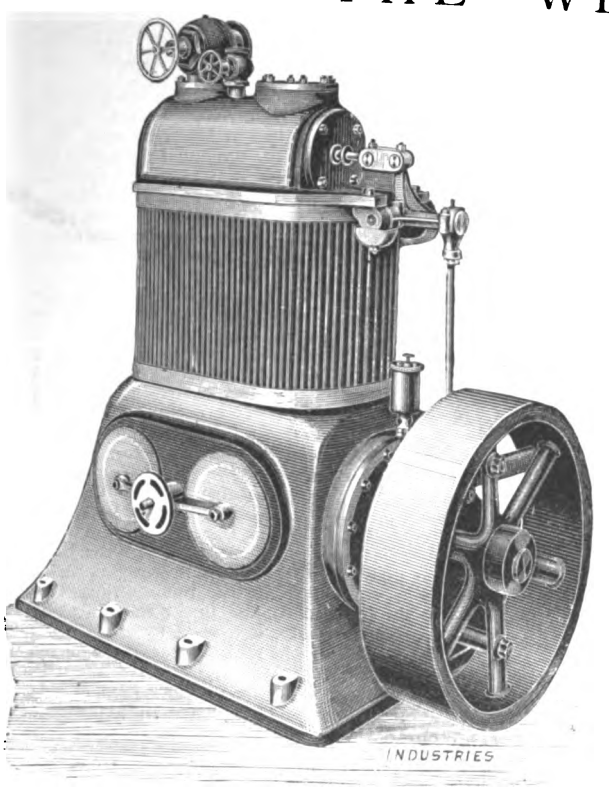


PAVING BLOCKS.—*W. Bignall, Nebraska City, Nebraska.*—The bricks used by the inventor for paving roads are provided with a vertical rib on two adjacent sides. The ribs are near the middle of their respective sides. By this arrangement the bricks may be placed in position on the roadway without any trouble at the right distance from each other, and a continuous space will be left round their corners, so providing a suitable space for filling up with concrete. Two claims are made.—No. 382683, dated 15th May, 1888.

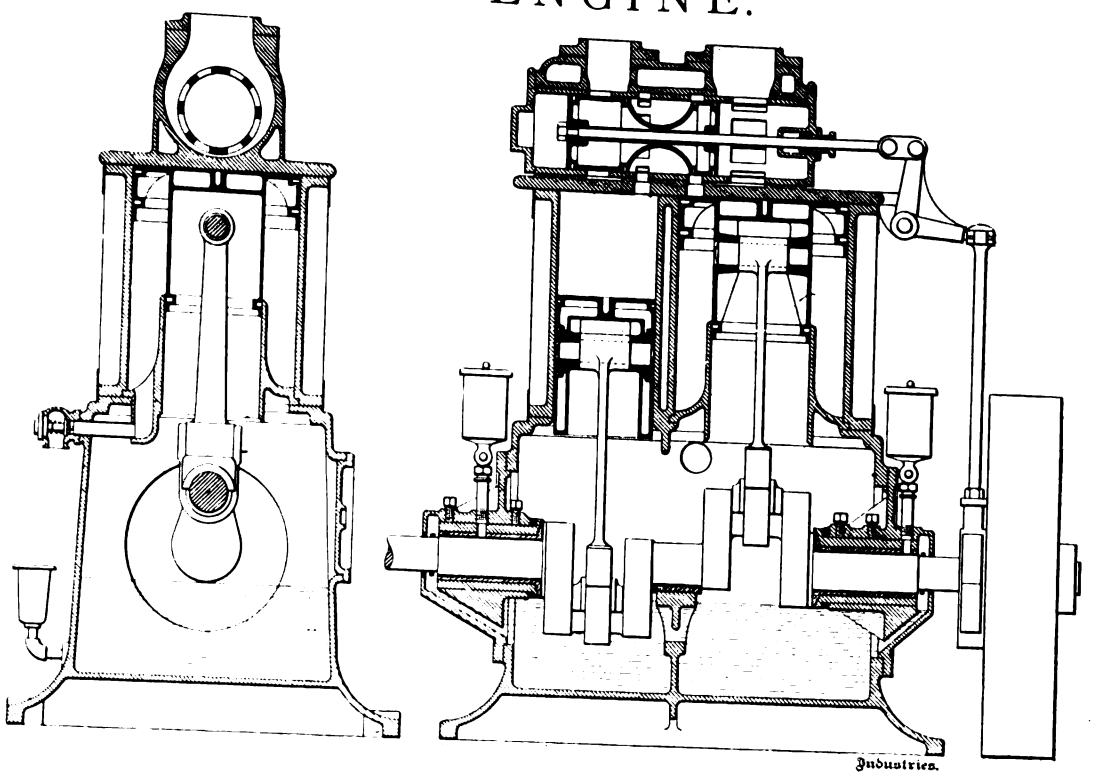
SAND MOULDING MACHINE.—*J. R. Davies, Pullman, Illinois.*—The accompanying figure shows a section of the improved part of the machine. The box G is capable of a horizontal sliding motion, and is also made vertically adjustable for the purpose of removing it from the flask E. The interior of the box G is

divided into a series of non-intercommunicating chambers M K N O. Intermediate between these chambers are the cylinders L, and the pistons I which work in them carry the tamping rammers I^1. The water which supplies the hydraulic pressure to the pistons enters the chambers through the pipes A, and leaves through the pipes F. When the sand has been placed over the object to be moulded the tamping heads are pressed down by the water in the cylinders L. By this arrangement of separate tamping heads and cylinders the pressure is distributed more uniformly through the sand, and the mould is thus made firmer. Ten claims are made.—No. 382217, dated 1st May, 1888.

HYDRAULIC VALVE.—*M. B. Kirker, McKee's Rocks, Pennsylvania.*—The accompanying figure shows a section of the valve which is intended for regulating the pressure and supply of water to a hydraulic engine. The valve casing contains a cylindrical chamber E, into which the water enters by the port C. The



water proceeds to the machine through the port D. A valve stem F passes through the chamber and through the cylindrical bore between the chamber E and port D, and is actuated in a vertical direction by a suitable mechanism at its head; two packing discs H I are fitted to the stem, the concavity being on that side of the disc which is foremost during the motion of the valve over the port when the disc is under pressure. Three claims are made for this arrangement of valve stem, ports, and packing discs.—No. 382003, dated 1st May, 1888.



The full specifications of the British and United States patents, and the Official Journals of the German Patent Office, from which the above abstracts have been compiled, and the Official Journal of the United States Patent Office, may be seen by subscribers and clients at the Reading Room, Manchester Office of INDUSTRIES, *where also Patent Indexes from* A.D. 1617 *may be consulted. Copies of the British specifications may be obtained on application to* H. READER LACK, Esq., *Comptroller-General, Patent Office, Southampton Buildings, London, W.C. The published price must be remitted, together with a sum sufficient to cover postage, which may be reckoned at ½d. for every 10d. or fraction of 10d. Remittances exceeding one shilling must be made by Post Office Order.*

THE WESTINGHOUSE ENGINE.

General View.

Sectional Elevations.

THE WESTINGHOUSE ENGINE.

The requirements of electric lighting have stimulated engine builders to produce high speed steam engines which should not only be free from the mechanical defects which appertained to the so-called rotary high speed engines of ten years ago, but should equal, and if possible excel, the ordinary steam engine in point of economy. Thus new types of high speed engines have been developed, amongst which the best known are the engines of Tower, Rigg, Parsons, Willans, and Chandler. In the matter of economy, the Willans engine is probably ahead of its competitors in England; but it is run very hard by the new Westinghouse engine, which is now largely used in central electric light stations in America. As will be seen from the above illustrations, the engine is exceedingly simple in construction. Steam is admitted to both cylinders by a single piston slide valve worked from an eccentric by means of a bell crank lever. The valve is placed on the top of the cylinders, in order to reduce the length of steam passages to a minimum. The admission is controlled by a centrifugal governor within the fly wheel, acting upon the eccentric sheave. To prevent the low pressure piston from overtaking the crank on the upward stroke, and thus causing knocking, an ingenious contrivance has been adopted. As will be seen from our illustrations, the low pressure piston is provided with a central trunk, the annular space between piston and trunk being in communication with the external atmosphere by means of a valve which opens outwards. On the low pressure piston descending, the air in the annular space is compressed until its pressure has risen sufficiently to force open the valve. When the piston ascends, the valve closes and the air in the annular space expands, producing a partial vacuum, and thus keeping a downward pressure on the connecting rod.

It will be seen that Mr. Westinghouse produces by means of a partial vacuum the same result as is produced in the Willans engine by means of the air buffer. The high pressure piston being lighter is not provided with the annular air chamber; but the latter may, of course, be applied to the high pressure as well as to the low pressure cylinder in larger engines. An exhaustive series of steam trials was carried out during February last at the works of the Westinghouse Company, in Pittsburg, with a compound engine having 14in. and 24in. cylinders by 14in. stroke. The speed throughout the trial was kept at 250 revolutions. The accompanying tables of results have been sent to us from an American correspondent.

EMERY TESTING MACHINE.*

(Concluded from page 590.)

Fulcrum Plates.—Figs. 1 and 2 (shown on page 632) are two general views of the machine, Fig. 1 being a front elevation, and Fig. 2 a side elevation of the testing machine proper. In Fig. 3 is shown a plan of the straining mechanism. In Figs. 4 and 5 is illustrated the scale case, containing the mechanism for measuring and indicating the strains on the specimen, and the valves for controlling the action of the machine. Fig. 4 is a front elevation, and Fig 5 a plan of the scale case. In Figs. 10 to 15 and Figs. 6, 7, 9, 19, and 20 are illustrated various details. Figs. 21 to 28 and Figs. 16, 17, and 18 show the construction of the holders for tension and compression, and the apparatus for transverse tests.

Hydraulic Chambers.—The testing machine proper, shown in Figs. 1, 2, and 3, comprises the apparatus for holding and straining the specimen to be tested. The bed or base of the machine, as shown more clearly in Fig. 12, consists of a hollow rectangular frame F of cast iron, having two rigid bearing surfaces, one near the bottom and the other at the top, suitably united at their four corners, and thus leaving an interior open space. Rising from the bed, as seen in Figs. 1 and 2, are the two main adjusting screws M, carrying the hydraulic straining press P, the vertical adjustment of which is effected by means of the long nuts (Fig. 12). The nuts are geared together, and are rotated equally by means of a vertical shaft and bevel gearing worked by a handle or belt pulley at X (Figs. 1 and 2). The fluid pressure is conveyed to the ram through the jointed tubes T. The hydraulic press acts in one direction for tension, and in the reverse direction for compression and transverse strain; in either case its pressure is directly transmitted to the specimen A. The upper holder U for holding the specimen is attached direct to the ram of the straining press; the lower holder L is secured to the head block H, which in turn is connected by four steel bolts to the bottom block B, as shown in Fig. 11; these two blocks thus constitute a yoke or stirrup, which envelopes the hydraulic chamber or support S. This yoke is secured in proper position within the frame F by horizontal fixing plates of thin tempered steel, which hold it steady laterally, while leaving it free to move vertically through the minute range desired. The transverse beams G G pass between the yoke blocks H and B, and bear at their outer ends against the cross beams of the frame F. These transverse beams are similarly free to move vertically within slight limits, but are stayed against all lateral motion by flexible fixing rods. Between the transverse beams G G is the hydraulic chamber or support S, which is 25in. in diameter, and 3in. in axial length. The space between the blocks H and B is 0·007in. more than the thickness of the parts contained between them; and this clearance is transferred from the upper to the lower block, according to the direction in which the specimen is strained. The change is conveniently effected by a single turn of a pair of nuts above the caps of the load springs R (Figs. 22 and 23). The function of these initial load springs is also to take up and absorb all clearance or back lash; in changing the apparatus from tension to compression, the clearance or back lash is taken up in the right direction by the load springs, and the scale is then balanced with the parts in this position before commencing a test. The strain received by the specimen from the straining press P is directly transmitted through the yoke and beams G G to the hydraulic support S. No frictional resistance is developed under the action of the load; but a slight elastic resistance is developed in the fixing and stay plates, by the minute yielding of the parts under pressure. This resistance, however, is not lost or absorbed, but is all of it taken account of in the rating of the scale. The strains resulting from tests of compression or tension act identically except in direction, the former acting downward on the support, and the latter upward. The hydraulic support, shown in section and plan in Figs. 14 and 15, consists essentially of a base block K, 24in. in diameter, to which is bolted a ring N, and within the latter is a movable disc or piston D. The lining diaphragm of the base block and the working diaphragm of the piston are each made of soft sheet brass 0·005in. thick; and each as originally made is flat and smooth. These parts are put together as shown in Figs. 13 and 14; and as soon as the fluid pressure is introduced between the two diaphragms, it forces the thin brass into the annular grooves turned in the base and piston (Fig. 15), thus interlocking each diaphragm with its rigid backing, and relieving it from all looseness or tendency to buckle under changes of temperature. The diaphragms thus act simply as linings to prevent the escape of the contained fluid. An interval of 0·1in. is allowed between the piston D and the ring N (Fig. 14), and through this interval all round the piston the diaphragm is unsupported. The piston is thus permitted to move vertically, the exposed portion of the diaphragm acting as a flexible joint or hinge. The motion of the piston, however, being due chiefly to the compression of the liquid and its contained air, is limited to a maximum of less than 0·001in. While thus left free to move vertically within these minute limits, the piston is secured against all lateral motion by the annular fixing diaphragm at its upper face, and the working diaphragm at its lower face (Fig. 14). The smaller hydraulic chamber or "reducer" R, contained in the scale case, is shown in enlarged size in Fig. 6. It consists of a steel base block and ring, with a movable disc or piston resting on the pressure diaphragm. In this case the brass lining diaphragm is dispensed with, and a single diaphragm of tempered steel is employed, which is best shown in Fig. 13, and consists of a flat disc of spring steel tempered, 0·006 in. in thickness. It is sealed by bedding against a lead ring contained between two bronze rings, the fluid being retained between the under side of the diaphragm and the upper surface of the steel bed. The annular space between the piston D and the ring N is 0·06in., which is the amount of free span of the diaphragm to permit of the free vertical movement of the piston under pressure. An annular fixing diaphragm is used to centre and guide the piston, in the same manner as in the case of the larger support. In Fig. 8 is shown in enlarged size the form of hydraulic support used in railway weighing machines, which clearly illustrates the construction and action of this important element of the Emery system. The cap C is placed over the support to exclude dirt, and the platform of the scale rests on this cap, the pressure being transmitted by it through a block of rubber R to the head of the pressure column P. The pressure thus received is supported on the thin film of fluid contained between the bottom of

the column P and the base piece B, this pressure being communicated through the small copper tube T to the scale mechanism by which it is weighed. The fluid employed for filling the hydraulic supports and chambers is either refined kerosene oil or alcohol and glycerine. No waste of this fluid occurs in use, either from leakage or evaporation, all of the joints in the hydraulic support and reducer, and the connecting tube between them, being made absolutely tight without packings.

Scale Case and Levers.—The hydraulic portion of the weighing mechanism terminates at the reducing chamber. Referring to Fig. 4, the reducer R is seen in position in the scale case. The pressure of the liquid in the reducer, tending to separate the piston and the fixed block K, acts against the frame A above as an abutment, and is received upon the transverse block B below, which in turn transmits it through the first steel fulcrum plate to the first or main lever M. This fulcrum plate carries about 10,000lb., being $\frac{1}{30}$th of the load put upon the hydraulic support in the testing machine. As shown in Fig. 9, it consists of a thin piece of tempered steel, 0·06in. thick by 0·3in. long and 10in. wide, forced under the heavy pressure of 40,000lb. or 50,000lb. into seats in the two pieces which it connects; the interval between the two pieces is 0·15in., which is the width of the free or exposed portion of the fulcrum plate. The relation and arrangement of the several beams composing the lever system of the scale are shown also in the outline (Figs. 19 and 20). The right hand end of the first lever M is connected with the fixed frame of the scale case by a similar fulcrum plate, so that the downward pressure from the reducer received through the block B tends to depress the left hand end of the first lever M. At the left hand end this lever is connected by another smaller fulcrum plate to a vertical link L, contained in a recess of the scale frame, and extending upwards through the latter, its head being seen again close to the indicator scale in the upper part of the case. The action of the reducer thus causes downward pressure on the link L, the upper end of which is connected by a thin fulcrum plate, 4in. wide by 0·02in. thick, to the overhanging short arm of the second lever S; the fulcrum supporting the latter is slightly to the right of the connection with the link L, and consists, as in the previous case, of a flat steel fulcrum plate, one edge of which is fixed in the under side of the lever S, and the other edge in an abutment of the scale frame. The pressure transmitted from the reducer thus tends to depress the left hand end of the second lever S, and to elevate proportionately its right hand end. The third and last lever consists of the indicator bar I, which is suspended at its right hand end from the scale frame by two thin fulcrum plates, set 4in. apart, each of them being 0·005in. thick by 0·3in. long, and here used in tension; whereas all the fulcrums previously described are used under compression only. In like manner, the right hand end of the indicator bar I is connected with the second lever S by a thin fulcrum plate which is also always in tension, owing to the fact that the indicator bar, aided by the small sliding weight W which it carries, overbalances by reason of its great leverage the combined unbalanced weight of the levers M and S, of the vertical link L, and of their connected parts. The balancing of all of these movable parts, and the adjustment of the scale so that the indicator stands exactly at the zero point when the machine is unloaded, are effected by sliding the balance weight W along the indicator bar to the proper position, and there fixing it by a thumb screw in the weight. The sensitising weight E, on the right hand overhanging end of the indicator bar, is capable of vertical adjustment, the effect of which is to alter the centre of gravity of the indicator bar relatively to its point of suspension, and thus to change the sensitiveness of the scale. Usually this weight is so adjusted that the point of the indicator bar shall move one division on its scale for each 10lb. of load applied to the specimen. The amount of vibration of the indicator over its scale thus affords a most convenient means of reading small variations in the load. As already explained, the total multiplication of the lever system is 1 to 20,000. This enormous velocity ratio is made possible, without the great loss inherent in the knife edge system from friction and from change in fulcrum distances, by the use of the system of plate fulcrums, whereby the two fulcrums which determine the length of the short arm of each lever can properly be brought into close proximity, and the leverage in each case made proportionately large. As each succeeding leverage is multiplied by that preceding it, the total becomes rapidly very great. Hence a very small weight on the indicator bar counterbalances a very large force acting through the reducer on the first lever. Conversely, it follows that the amount of motion of the indicator bar sufficient to be distinctly visible, say 0·1in., is reduced, through the action of the lever system, to $\frac{1}{20000}$th part, that is $\frac{1}{2000000}$th part of an inch, at the transverse block B (Fig. 4), which bears against the reducing chamber R; this is therefore the motion of the piston of the reducing chamber, while $\frac{1}{20000000}$th of an inch is the corresponding motion of the piston of the hydraulic support in the testing machine. The motion of the latter piston, and of the flexible diaphragm on which it rests, thus becomes exceedingly minute, and insensible to sight or touch. This fact should be borne in mind in considering the motion in both the hydraulic chambers, in each of which it is so extremely minute that their functions can be more appropriately described as consisting simply in the reception and transmission of pressures of varying intensity, rather than in motion of one part relatively to the other. Referring again to Fig. 4, it will be seen that each increase of pressure applied to the specimen tends to depress the left hand end of the first lever M, and therefore to depress similarly the point of the indicator bar I. Downward motion of the indicator therefore denotes increase of load and the need of additional weights to balance it, while upward motion of the indicator denotes a reduction of the load or an excess of counterpoise. The operator thus quickly learns that if the point of the indicator falls below the zero mark he must apply more counterpoise, and when it rises above the zero mark he must decrease the counterpoise. There are four series of counterpoise weights, each series controlled respectively by one of the four handles H, through a set of levers connecting these handles with the frames which carry the weights when they are not required in the poise rods of the beam. Briefly described, each of the successive series of weights is in the ratio of 10 to 1; each series except the last comprises nine individual weights, of which any desired number can be instantly applied to or taken off from the

Digitized by Google

poise rods of the scale beam by a simple motion of the handles. The operator uses only two of these handles at a time, watching the indicator bar and keeping the scale beam balanced within limits less than its full vibration; and by noting the pointers carried by the four vertical rods connected with the handles H, he has always before him a clear indication of the position of the whole series of poise weights. This record remains undisturbed by the breaking of a specimen, and can be accurately noted afterwards. In accurate work the position of the indicator bar at the moment of rupture should also be noted, and the load it indicates should be added or subtracted before the load indicated by the poise weights is recorded. The strains upon the specimens are controlled by valves contained in the lower part of the scale case (Fig. 4), and worked by hand wheels which are conveniently grouped together to the right of the handles H that control the poise weights. The hand wheel V controls the main inlet valve between the pump or accumulator and the testing machine; and the smaller hand wheel on the top of it controls a smaller and finely graduated valve contained within the main valve, thus affording convenience for all possible adjustments of flow; the rate of motion of the ram can be adjusted to a maximum of 1ft. per minute, or to a minimum as small as 0·001in. in half an hour. The handle D controls a set of reversing valves, which determine the direction of flow from the pump or accumulator into the hydraulic cylinder or straining press of the testing machine. When standing in the position shown in Figs. 4 and 5, these valves cause the liquid from the pump or accumulator to flow to the under side of the piston, thus moving it upward, as required in tests of tension; turning the handle D to its other position, that is through an angle of 180°, reverses the direction of flow, and causes the piston to descend, as required in tests of compression. A single motion therefore of the handle D enables the operator to reverse and entirely control the direction of motion of the piston or ram of the straining press, whether for the purpose of adjusting it for making a test, or for the actual making of the test itself. The two handles F control a by-pass or circulating valve, the opening of which lets off the pressure in the straining cylinder to any desired extent, by permitting the escape of liquid therefrom into the reservoir or cistern. All the weighing mechanism contained in the scale case is protected from dust, and from currents of air, by a plate glass sash in front, as seen in Fig. 4. In addition to this, a shutter of wood can be let down over the sash, which, meeting a similar folding shutter in the lower part of the case, entirely closes and protects the weighing mechanism and valve gear. This shutter being secured by a lock and key, the machine is safe from interference or injury. The only connections between the scale case and the testing machine proper consist of the small copper tube connecting the hydraulic support with the reducer, and of the pipe connections between the valves in the scale case and the jointed pipes T on the testing machine (Fig. 1). The scale case can therefore be placed in any desired position relatively to the testing machine, and is disconnected from the latter so far as relates to transmission of shock or jar resulting from the rupture of specimens. The eliminations of all back lash, and the careful provision for the absorption of all shock and recoil, combine to reduce the effect of the rupture of specimens to a minimum which is so surprisingly small as to be hardly credible until actually seen. An observer may safely keep his hand on the platen of the testing machine while a specimen of the largest size is tested to rupture, no sensible jar being experienced even at the instant of rupture. Indeed, except for the pistol-like report caused by the sudden rupture of a large specimen, particularly of metal having a high modulus of elasticity, such as steel with a high percentage of carbon, the senses would hardly take cognisance of the fact that rupture had occurred.

Holding of Specimens.—In Figs. 16 to 18 is shown in detail the apparatus for holding specimens in tests for tension. Each of the tension holders consists of a cylindrical steel shell H, properly secured to the platen of the machine and to the ram of the straining cylinder. The outer end of this shell, as seen in Fig. 16, has conical seats bored within it, in which are two cylindrical wedges D (Figs. 16 and 18). Suitable jaws or clamps are fitted to the internal facings of these cylindrical wedges, for adapting them to receive round, square, or flat specimens of the various commercial sizes. The jaws having been opened sufficiently to admit the specimen are again closed upon it, thus giving a slight initial grip, after which the motion of the straining press in applying strains to the specimen causes the cylindrical wedges to be drawn outward in the shell of the holder, thus forcing them still more tightly upon the specimen by reason of the incline or wedge form of the cavity within which they slide. Two transverse following wedges W are provided, which, under the pressure of spiral springs coiled in the two spring boxes R on each side of the holder and acting through cords, tend to close together, and thus follow up the gripping wedges, as the latter move outward under the action of the increasing strain upon the specimen. The result is that when rupture takes place, little or no back lash is possible in the holders, each of which acts substantially as a solid block in transmitting the shock to the parts which, as already stated, are so constructed as to receive and absorb it without injury. Figs. 21, 25, and 26 show the arrangement of platforms used in making tests under compression. Fig. 26 is a sectional view of the compression platform as applied to the bottom of the ram of the straining press. Upon the end of the ram is screwed a nut or sleeve, which in turn carries and supports the bed B. This bed has a convex spherical surface, against which is fitted the head or platen P, having a corresponding concave spherical surface. The latter piece is provided with six adjusting screws, by means of which it can be revolved or shifted relatively to the convex bed, so as to cause the outer face of the platen P to take any desired angle relatively to the axis of the machine or specimen. The adjustable platforms make it unnecessary to observe any special care in securing parallelism between the ends of a specimen to be tested under compression. All that is needed is that each end should be a true plane; and if these two planes are not exactly parallel, either or both of the adjustable platforms is so adjusted that the plane of its bearing face coincides with that of the end of the specimen (Fig. 21), while the axis of the specimen remains parallel with that of the machine. This being done, the test can be proceeded with under assurance that the results obtained will be exactly the same as though the ends of the specimen were not only true planes, but were also exactly parallel. The facility thus afforded tends not only to more correct results in testing, but to great economy and convenience in the preparation of specimens. When it is desired, the face of the platen P can be set normal to the axis of the machine, in which position it is shown in Fig. 26. The apparatus for transverse tests is shown in Figs. 22 to 24. A heavy rectangular bar B of steel is placed upon the platen P of the machine, and suitably secured there. Its outer ends are supported by inclined struts T, the lower ends of which are stepped into the foot block of the stirrup or yoke shown in Fig. 11. Downward pressure on the bar B acts therefore upon the testing machine precisely as similar pressure transmitted through a specimen when tested in compression. Sliding on the top of the bar B are two supports or bearings S on which rests the specimen A. These bearings may be set at any desired distance apart, according to the length of the span desired for making the test. Their positions are accurately indicated by the scale engraved on the side of the bar B. A smaller but similar apparatus is shown in Figs. 27 and 28, designed for transverse tests of short specimens only. This is identical with the larger apparatus, except that the bearing blocks are moved and set by a right and left hand screw worked by a crank handle. An ordinate bar D is suspended within these bearing blocks, in such a manner as to be entirely free from distortion during the progress of a test, thus affording a true base line from which, by means of the sliding gauge shown in Fig. 28, the deflections of the specimen can be accurately measured.

Rating.—The mode of rating the action of the Emery testing machine with standard dead weights is as follows: The internal diameter of the larger hydraulic support when completed can be accurately measured with the greatest precision. The exact diameter of the reducer, and the ratio between the two hydraulic chambers, are not material, and practically are never considered, except approximately when designing the machine. In like manner, the fulcrum distances of the levers are originally fixed approximately, but in actual construction are never gauged or in any way closely determined in the adjustment and rating of the scale. The aggregate velocity ratio between the platform movement and the movement of each poise weight is determined by actual loads simultaneously placed on each and balanced. The loads applied to the platform are obtained from a special rating machine, the action of which has been carefully determined at each point with actual dead loads, so that its indications are known to be correct. By means of this rating machine known loads are applied to the hydraulic support of each testing machine up to its maximum capacity. The exact weight required on each poise rod to balance a known load on the machine is thus ascertained by actual test, and the poise weights are then carefully adjusted thereto. Each of these weights is electro-plated with gold to protect it from oxidation, and are all contained in a dust tight case behind plate glass; in use they are applied without friction, and without being touched by the hand. The ratio between the two hydraulic chambers remains absolutely without change; and in like manner the fulcrum distances of the lever system are unchangeable. Inasmuch therefore as the aggregate ratio between the larger hydraulic chamber which receives the load, and the weights by which the intensity of the load is measured, is thus readily determined by actual test throughout the entire range of the machine, and as this ratio remains constant, it follows that the machine when once adjusted and rated will continue unchanged indefinitely; and this conclusion is confirmed by actual experience. In machines based upon the principle of the common knife edge scale, on the contrary, the test with known dead loads usually covers only a small portion of the range of the machine; and it is assumed that the action of the machine throughout the remainder or higher part of its range will be the same proportionately as within the lower range tested by actual loads. This assumption is undoubtedly erroneous, for experience has shown that absolute or even approximate rigidity in such machines is impossible, and that the yielding and bending of the parts of a knife edge scale inevitably cause serious disturbances in the fulcrum distances and also in the frictional resistances, while for neither of these disturbances does the knife edge system provide any compensation. Extensive experience has established the fact that the principles involved in the construction of the Emery machines, and the methods adopted in adjusting them, are such that a degree of precision has been attained beyond anything previously accomplished, and that this precision is maintained unimpaired even under the exceptionally severe conditions obtaining in the use of testing machines of large capacities. As indicative of unsuspected sources of error in the earlier and cruder testing machines, particularly those in which the applied strains are measured by simply gauging the hydraulic pressure in the straining cylinder, it may be mentioned that a test was recently made of one of the largest machines of that kind in the United States, by having a large and long bar of steel tested for extension in the Watertown machine, the test being carefully kept within the elastic limits of the metal, and the stretch accurately noted by micrometer gauges at each successive increment of the load. The specimen being released from strain was found to return to its original form, thus showing conclusively that it had not been strained up to its elastic point. The same specimen was then subjected to test in the hydraulic machine above mentioned, and its extensions were again noted by micrometer gauges, the specimen thus serving as a delicate dynamometer by which to determine the differences in the readings of the two machines. With loadings up to a maximum of 400,000lb. these differences, under precisely equal extensions of the specimen, varied from 4 per cent. to 16 per cent. of the applied loads, the larger proportional discrepancies occurring with the smallest loads. These results are corroborated by other experiments which have been made with the Watertown machine, and justify the assertion that in ordinary testing machines the rate of error or variation, due to loss from friction and to incorrect methods of weighing, covers a wide range, amounting in some cases to probably more than 20 per cent., and rarely, if ever, to less than 5 per cent. in the case of hydraulic machines. For certain commercial purposes this approximation to facts may suffice; but for the more accurate purposes of scientific work, as well as for ultimate economy and safety even in ordinary commercial work, testing machines of greater accuracy will inevitably be required. The appliances now described meet these requirements in the fullest degree; they have been extended in practice to machines ranging in capacity from 70,000lb. to 800,000lb., and are capable of advantageous application to machines of any desired capacity, the designs for a machine of 1,200,000lb. capacity having already been prepared.

From the foregoing description the writer hopes it will be seen that the inventions of Mr. Emery have led to the production of a machine capable of developing and controlling forces amounting to hundreds of tons, and of so utilising and weighing these forces as to entitle the machine to take rank as a true instrument of precision. This machine, it is believed, is the first in which all of the factors of the case have been successfully provided for, so that all sources of error and doubt are eliminated, and results are made possible which in the fullest sense are precise and accurate. These important results are obtained by a degree of precision and perfection heretofore rarely if ever attained, or even attempted, in mechanism of such large dimensions. At the same time, unusual facility has been obtained for the convenient manipulation of specimens, and for the adaptation of the machine to the different kinds of tests.

BRITISH WATCH INDUSTRY.

At a recent meeting of the Balloon Society of Great Britain, an address was given by Mr. James Kendal on "The British Watch Industry." The lecturer stated that the sun dial of Ahaz is the first record of a timekeeper, that the obelisks of the Egyptians were intended as gnomons, and that the next record of a sun dial was the hemicycle of the Chaldean astronomer, Berosus, 450 B.C. The clepsydra, or water clock, was the next contrivance for measuring time, used by the Chaldeans; but to whomsoever the early discovery of timekeepers may be due, he said that clocks were set up in churches as early as 1174, and in the reign of Henry VI. a pension was granted to the Dean of St. Stephen's for taking charge of a clock in Palace Yard, Westminster. In 1326, Richard Wallingford, abbot of St. Alban's, placed a clock in his monastery which showed the hours, the motion of the sun, the changes of the moon, the ebb and flow of the tide, &c., and the account of this clock is still preserved in the Bodleian Library at Oxford. In 1340 Peter Rightfoot, a monk of Glastonbury Abbey, made a clock which, at the Reformation, was removed to Wells Cathedral, and the original is now to be seen at the South Kensington Museum. The clock for the Strasburg Cathedral was begun in 1352, and finally completed in 1574 by Conradus Daspodius. The use of the pendulum for securing accuracy of time was first adopted by Vincent Galileo, in 1648, and the anchor escapement, for regulating it, by Dr. Hook, 1666; and he stated that little progress was made since that time until Mr. Dennison, now Lord Grimthorpe, designed the clock for the Victoria Tower of the Houses of Parliament, in 1854. The most remarkable episode in the construction of timekeepers is the lever escapement, invented by Thomas Mudge, in 1770, the last epoch in the history of the watch. The progress of the last fifty years in watch making has consisted rather in the perfection of proportions than in the introduction of new principles, for even the invention of winding from the pendant, instead of a watch key, is tardy appreciation of an invention patented more than half a century ago. At the International Inventions Exhibition of 1885, Kendal and Dent exhibited a horological novelty of a watch with two dials placed back to back, with the movement between them. On one dial was marked the old divisions of twelve hours, and on the other the suggested hour circle with twenty-four divisions, and this invention attracted considerable attention from horologists and mechanicians. Mr. Kendal then referred to the important uses to which timekeepers are devoted by the use of marine chronometers to enable the navigator to ascertain his longitude as he travels over the sea. In 1714 the English Government offered a reward of £10,000 for determining the longitude to within sixty miles; £15,000 within forty miles; and £20,000 within thirty miles; and this reward was secured, after thirty years of unremitting labour, by John Harrison, a carpenter, of Faulby, in Yorkshire, who succeeded, in 1764, in producing the present marine chronometer.

TRAVELLING CAISSONS.

The illustrations shown on pages 634 and 635 represent a new travelling caisson, designed by Mr. W. R. Kinipple, of 2, Westminster Chambers, S.W., for the Russian Minister of Marine. The caisson is being built in Russia, and in general principle is similar to some caissons which were constructed to Mr. Kinipple's design in this country and abroad. Fig. 2 shows the dock entrance with the caisson in place, and the dotted lines indicate the position of the caisson when it is drawn back into its chamber, so as to leave a free passage between the sea and the dock. It will be noticed that the sides

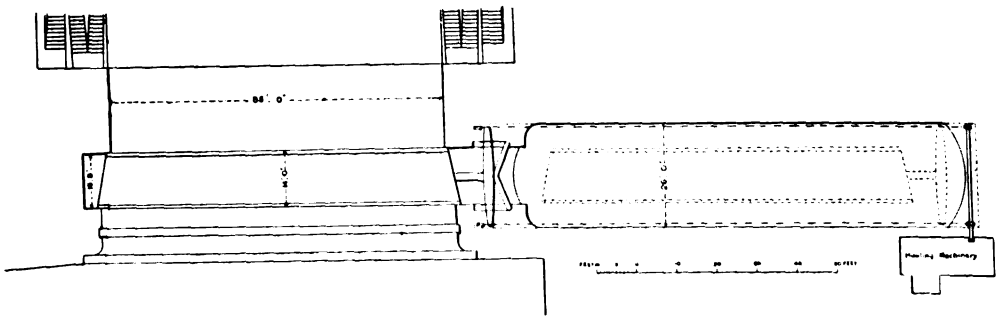

FIG. 2.

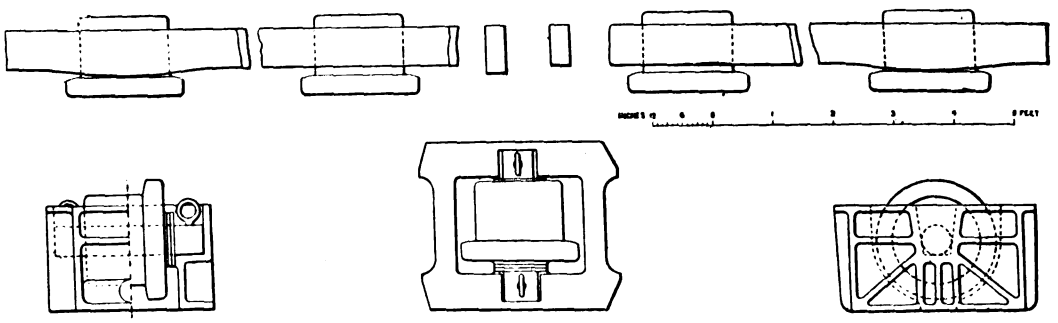

FIG. 3.

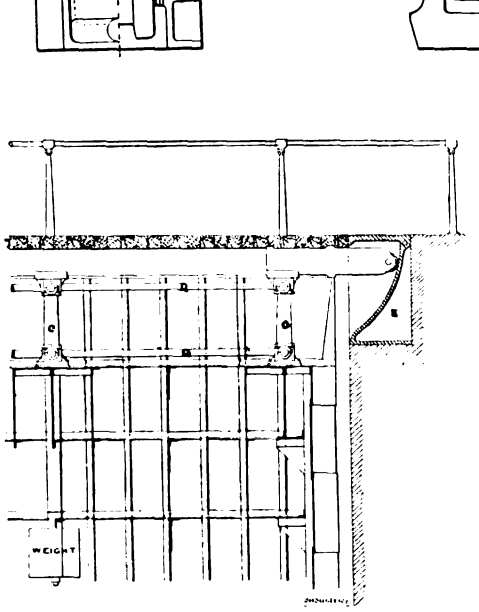

FIG. 4.

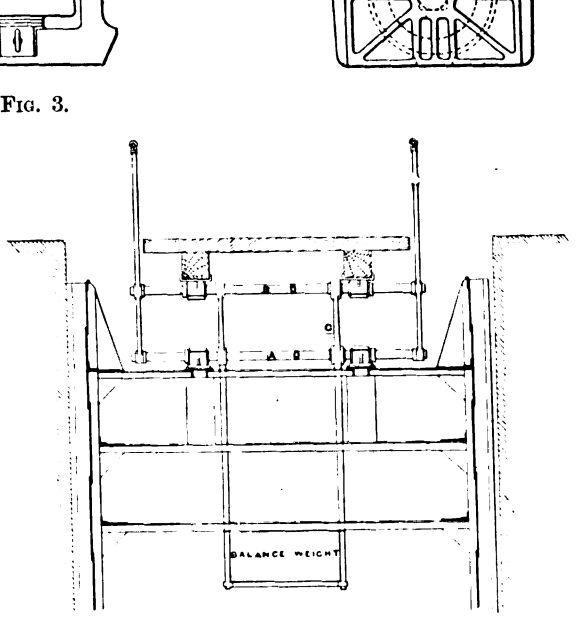

FIG. 5.

of the caisson are vertical, but bevelled horizontally, the larger surface being presented to the sea. The object of bevelling the sides is to provide an easy means for turning the caisson round within the dock entrance, and floating it out for repairs. The caisson is provided with two steel keels, which are of varying width, and run on cast iron rollers, as shown in Fig. 3, and in the front elevation shown on the opposite page. The rollers are fixed on the masonry at the bottom of the dock entrance, but are below the sill proper, so as not to be exposed to damage from passing vessels. The rollers are provided with flanges, which constrain the keel at its wider portions. When the caisson is in position for closing the entrance, only the narrow parts of the keels lie immediately above the rollers, thus giving the water on either side free play to force the caisson against the granite walls of the recess on either side. The joint is made by greenheart facing pieces, 16in. in width, which run along the bottom edges and up the sides. When the caisson is drawn back, the wider portions of one or the other of the keels come against the flanges of the rollers, and force the edge of the caisson away from the facing in the masonry recess, so that no loss of power from friction and no undue wear take place. If the caisson is to be removed, it is first run a short distance into its chamber, and then floated out on the tide. The difference in width between the inside and outside face being 5ft., and the caisson being a few inches narrower than the recesses, this operation is easily performed. The operation of hauling the caisson in and out is performed by means of a hauling bar and yoke, to which are attached endless chains, set in motion by a hauling shaft shown in Fig. 2. Power is supplied by a special 30 h.p. steam engine, fixed in a house at the end of the caisson chamber. The caisson is a steel structure built up of angle and T sections, and the sides are formed of plates varying in thickness from $\frac{5}{8}$in. to $\frac{7}{16}$in. The plates are stiffened by vertical angle iron frames, 18in. apart. In addition to the top deck there are two internal decks, formed of $\frac{3}{8}$in. plating, with butt joints and straps. The first of these, which is about one-third of the way down, is water tight; and the other, about two-thirds down, is braced like a horizontal lattice girder, in order to withstand the horizontal pressure of the water. As will be seen from the front elevation, communication between the sea and the dock can be established by means of three iron tubes, each with a sluice valve in the centre worked from the upper deck. There are also four smaller sluice valves just above the water tight deck, which serve to run water in and out of the space above this deck, and thus control the buoyancy of the structure. Three vertical air shafts, extending from the top deck to the lower water tight deck, give access to the interior of the caisson, and these shafts are also used for adding or withdrawing ballast. The caisson is 38ft. 6in. deep, and has a displacement of 854 tons. Its weight without ballast is 356 tons. At the bottom it is ballasted with 453 tons of concrete, and with an additional 60 tons of loose ballast, which can be removed when it is necessary to float the caisson away for repairs.

The use of sliding caissons instead of the ordinary dock gates is gaining favour, as may be gathered from the following list of caissons already constructed to Mr. Kinipple's design:—

	Span. ft.	in.
Garvel graving dock, Greenock	60	0
Quebec graving dock, Port Lewis	69	0
Aberdeen graving dock	50	0
Travelling bridge, West Harbour entrance, Greenock	103	6
James Watt dock, western entrance, Greenock	75	0

These were all constructed under the immediate supervision of Mr. Kinipple; but in the following cases his caissons have been employed by other engineers:—

	Span. ft.	in.
Monte Video	55	0
Govan graving dock, Glasgow	60	0
Cockatoo Island, New South Wales	88	0
Graving dock, Newport, Monmouthshire	50	0

In certain cases it is inconvenient to have the caisson chamber open at the top, and to provide for such cases Mr. Kinipple has designed an arrangement by which the upper deck is automatically lowered when the caisson is drawn into its chamber, thus enabling the latter to be covered over. This arrangement is illustrated in Figs. 4 and 5, being the design adopted in a caisson constructed for the Esquimault Harbour at the joint expense of the British Imperial Government, the Dominion of Canada, and the Government of British Columbia, and which was opened in June last year. The illustration shows the upper deck, or rather the gangway and rails, raised into the position they occupy when the caisson is across the dock entrance. The gangway is supported on a set of bars B joining the upper ends of the levers C, which are pivoted on the bars A. Some of the levers are prolonged downwards, and carry balance weights. The levers are joined by tie bars D, which constrain them to move simultaneously, and thus raise or lower the gangway on a kind of parallel motion. The balance weights are not quite sufficient to keep the gangway raised, and the operation of raising is performed by a casting E, with an inclined curve fixed to the masonry, and nose pieces fixed to the under side of the gangway. When the caisson is drawn across the dock entrance, the rollers on these nose pieces come in contact with the inclined curve, and as the caisson further advances they are forced upwards, thus bringing the deck into the position shown in our illustration. Upon drawing the caisson back, the rollers slide down the inclined surface, and the gangway is thereby lowered sufficiently for the caisson to pass into its covered chamber. It is interesting to note that M. Eiffel proposes to use similar caissons instead of the usual gates for the docks on the high level canal across the isthmus of Panama. In this case the caissons will run on rollers in the sill when across the entrance, and will hang from rollers attached to the under side of the covered chamber when withdrawn.

FOREIGN INDUSTRIES.

(From our own Correspondents.)

PARIS, 26TH JUNE, 1888.

THE COAL MARKET.—Tenders have been received for 10,000 tons of unscreened coal, and 17,000 tons of round coal, for the Assistance Publique de Paris. The lowest offer for the former was 7s. 2·9d. per ton; for the latter 10s. 2·9d. per ton was tendered for 6000 tons, the remaining 11,000 tons being offered at 10s. 7·2d. The imports of foreign coal in the first five months of the year amounted to 3,272,204 tons, against 3,469,675 tons in the corresponding period of 1887. Of this year's quantity, English produce formed 45·4 per cent.; Belgian, 45·1 per cent.; and German, 8·1 per cent. The average value per ton was 9s. 1·34d., exactly the same as last year. The imports of coke in the same time show an increase from 413,296 tons in 1887 to 437,156 tons in 1888.

ENGLISH COAL IN FRANCE.—Though English coal has hitherto held its ground in the markets of France, there is reason to expect a considerable loss of trade in the near future. The coal mining industry of the Nord is being steadily developed. By means of reduced railway charges, the market has been extended eastward at the expense of Belgian produce. Now an effort is to be made to push on in a westerly direction at the expense of the English import trade. The Government has this week officially sanctioned a new tariff, proposed by the Northern and Western Railways, for the transport of coal in trains of 250 tons at a reduced rate from the collieries of the Nord to Havre. The special object in view is to enable French producers to compete successfully with the importers of English coal, not only at Havre for bunker use, but for consumption in several of the western departments.

THE IRON MARKET.—There is a little more life in the iron market this week. Consumers are buying more freely, and as the stocks in the hands of the merchants are now small, there is a prospect of better prices. Business here is transacted on the basis of £5. 16s. for bars and £5. 8s. for joists. Some concession is allowed on these prices for large orders, but generally the rates are firmly maintained. Old rails are stationary at about £3. 6s. In the Haute Marne galvanised wire is in brisk demand, and manufacturers are fully occupied with orders in hand. Wire nails are less sought after. Within the last few days a better demand has sprung up for sheets. Founders are fairly busy, but prices remain low. The Forges de Saint Nazaire, an important works giving employment to some seven hundred men, has gone into voluntary liquidation, and will shortly be closed. This circumstance serves to strengthen the Paris market for the moment, but the prospect is discouraging for the future.

THE METAL MARKET.—The copper trade offers no new feature. Consumption has been greatly restricted, manufacturers buy only sufficient to cover present needs, stocks increase, and prices are firmly upheld by the syndicate. This is a state of things which no combination of capitalists can long maintain. Tin continues to droop in price. It is expected that the syndicate will come in again, and command the situation. Lead is firm. Spelter continues to decline.

STATE OF TRADE.—The trade of France seems to be wanting in recuperative force. The year is fast passing away without bringing the hoped-for improvement, and there is reason to fear that on the whole the home trade tends to shrink. Certainly the foreign trade is decreasing. The Customs returns for the first five months of the year show a decrease relatively to 1887, both in the imports and in the exports. The declared value of the former amounted to 1678·62 million francs, against 1715·85 millions, while the value of the latter is only 126·95 million francs, against 1281·08 millions last year. The diminution in the imports is wholly in raw materials and manufactured goods. Among the exports these classes show a slight increase, the decrease being in articles of food.

THE SUGAR BOUNTIES.—At a meeting of the Agricultural Committee of the Seine-et-Oise, held a few days ago, M. Léon Say denounced in strong terms the aim of the London Conference for the abolition of the sugar bounties. Feeling runs high on this question, and the agitation against the measure gains strength.

BERLIN, 25TH JUNE, 1888.

THE COAL MARKET.—At the present time Russian coal is imported into this country in considerable quantities, especially at the railway stations of Thorn, Bromberg, and Mocker, and is sold at cheaper rates than coal raised in Silesia. This is partly due to the low tariffs ruling on the Warsaw-Vienna Railway, and partly to the depreciation of the rouble. In order to reduce, if not to entirely exclude, Russian competition in the eastern districts of the empire, our colliery owners in Silesia are making great efforts to obtain a reduction in the rates for the carriage of their coal, and have already addressed a request for that purpose to the railway administration in Bromberg. On the lines bringing coals from the Westphalian districts, a reduction has already been granted, which will come into force on the 1st of next month. Herr F. Krupp, of Essen, is negotiating for the purchase of the Prinz Wilhelm and Prinz Heinrich pits.

THE IRON MARKET.—A few weeks ago, I referred to the proposal to establish a syndicate of fine sheet makers in Western Germany. A meeting has now been held, and it has been decided to form a syndicate with sales bureaux in Siegen and Dortmund, provided the co-operation of the Gutehoffnungshütte in Oberhausen, and the von Viebahn-Carlshütte, can be obtained, which works were not represented at the meeting, and provided that a satisfactory understanding is arrived at within a fortnight with the South German sheet rolling mills, viz., the Dillinger Hüttenwerke, de Wendel in Hayingen, and the Maximilianshütte in Bavaria. According to statistics just published, the total production of pig iron throughout the empire (including Luxembourg) during May amounted to 360,855 tons, of which 173,535 tons were forge pig and spiegel, 35,361 tons Bessemer pig, 108,248 tons Thomas iron, and 43,711 tons foundry pig. The production of crude iron during the corresponding period of 1887 amounted to 327,282 tons, thus showing a considerable increase. From the 1st January to the 31st May, 1888, there have been produced 1,756,310 tons of pig, as against 1,527,721 tons in the same period of the previous year. It is stated that the rolled iron syndicate in Upper Silesia have just sold a large quantity of rolled iron to a works outside of their usual sphere, and where they have to meet the competition of the rolled iron works of Western Germany. This transaction, which will be included in the third quarter of the year, has taken place at 135s. per ton, and shows an increase, as compared with the price ruling during the second quarter. The iron plate makers in Western Germany have collectively produced during May 10,333 tons of plates, against 9548 tons in April. The deliveries amounted in these months to 10,087 and 9111 tons respectively. New orders were received during May for 9035 tons, as compared with 7289 tons in April.

BRIQUETTES.—According to the annual report of the Society of Briquette Makers, which has just been published, the manufacture of briquettes is on the increase. At the end of 1887 the Society was composed of 59 works, having 171 presses, as compared with 52 works and 145 presses at the close of the previous year. The total quantity of briquettes produced during 1887 amounted to 1,059,020 tons, as against 953,177 tons in the previous year. The annual output of a single press was 6200 tons, or at the rate of about 25 tons daily, the number of working days being estimated at 250. The number of workpeople employed in this industry amounted to 1825.

DIRECT STEAMERS BETWEEN GERMANY AND THE EAST INDIES.—The President of the Association of German Jute Spinners, Privy Councillor Spiegelberg, has recently returned from a voyage to the East Indies, which was undertaken with the object of ascertaining whether direct steamship communication between the German ports and the East Indies could be established as a paying concern. In the report which he submitted to the Chancellor, he recommends the establishment of a direct line of steamers, mainly for the purpose of increasing the export trade in jute goods, the present method of shipping *viâ* London being too costly and cumbersome. But there are also other reasons. Herr Spiegelberg has found that in various parts of India there is a strong demand for German manufactures, and that German woollen goods are especially in request in Northern India, where they compete on favourable terms against English goods. The import of German salt into India would also appear to be a promising business. In addition to these advantages, which would result from a direct line of steamers, Herr Spiegelberg points out that there would be the advantage of increasing German prestige, and promoting the establishment of a German bank in India.

VIENNA, 25TH JUNE, 1888.

THE IRON MARKET.—No change of any importance has taken place in the iron market during the past week. Business in Vienna continues quiet, and but few transactions are taking place. The demand from retail dealers is at present very small, and wholesale dealers have considerable stocks on hand. No reductions in price, however, have been made, and this is mainly due to the firm attitude maintained by the various syndicates. In consequence of the dry weather prevailing during May, the harvest prospects in Southern Austria are somewhat unsatisfactory, and this is not without its effect on the market for agricultural implements. Building iron and sheets remain in moderate request. In Bohemia and the North generally the harvest is expected to be satisfactory, and to take place about the middle of July; business prospects for the latter half of the summer are consequently brighter. In Bohemia there has during the week been some activity in building iron, round and square bars, and castings, the latter more especially for gas and water mains and railways. Notwithstanding the slight spurt in business, prices have remained stationary. In sheets, business has become fairly brisk after a slight reduction in prices. The expected increase in the price of wire and wire nails resolved upon by the new syndicate has taken place, without, however, affecting the volume of business. Tin smiths, lock smiths, and other small iron industries are well employed. The characteristics of the Hungarian iron market are, on the whole, similar to those prevailing in Bohemia, with the exception that in Hungary there is momentarily a strong demand for crude iron.

THE VIENNA COMMERCIAL MUSEUM.—An important improvement has been introduced in the administration of this Institution, by the addition of a department in which information may be obtained regarding the Customs, tariffs, and other trade regulations in force in foreign countries. The general organisation of this department is similar to that of the Brussels Commercial Museum, with the exception that no information relating to railway tariffs can be obtained in the Vienna Museum; whereas this is one of the branches dealt with by the Brussels establishment. Information is given free of charge to merchants or their agents upon either verbal application or inquiry by letter. It is, however, preferred that inquiries should be in writing, giving exact particulars as to the country of destination, the character of the goods, the material employed in their manufacture, and where practicable accompanied by a sample. The department, in collecting information relating to foreign Customs tariffs, Excise duties, and other regulations affecting commerce, has been assisted by Austrian Consuls and Ambassadors abroad.

TRADE WITH ROUMANIA.—The protection policy of Austria and Roumania, which led to what is popularly known as the "Zoll-krieg," has, within the last two years, had the effect of almost completely killing trade between the two countries. The damage done does not only affect Austrian manufacturers, but also carrying companies. As an instance, I may mention that at the present moment the Danube Steam Navigation Company has hardly any Roumanian traffic; whilst a Russian company trading on the Danube do a fair amount of business with Roumania. The Russian Government, being eager to profit by the "Zoll-krieg," has established a sample warehouse at Bucharest, at an expenditure of 200,000 roubles, and this is stocked with samples of the production of Russian industry. As regards our Servian trade, the prospects are not much better than those of the Roumanian trade. Although Russian competition is not so strongly felt in Servia, the high tariffs on the Servian railways prove a great obstacle to our Eastern trade.

ELECTRIC LIGHTING.—Several leading manufacturers in Mariahilf and Neubau, Vienna, intend to erect a central electric light station for lighting both these districts. The estimated cost is £70,000, of which about one-third has already been subscribed, and it is not expected that there will be any difficulty in raising the balance among the commercial firms in the locality.

TELEPHONY.—The first telephone station under the direct control of the Government has been that established in the Rotunda, and steps have now been taken for the erection of six more stations in the town of Vienna itself. These will eventually be connected with the telephone exchanges in Baden, Vöslau, Wiener Neustadt, and Reichenau. A project is also under consideration for the establishment of a long distance telephone system between Prague and Vienna.

BRUSSELS, 26TH JUNE, 1888.

THE COAL MARKET.—Prices of industrial coal are well maintained, and rates for household coal are from 8s. 5d. to 10s. per ton. The *cahier de charges* (specification) for the new contracts for the supply of coal for the Belgian State railways contains some alterations as regards the test and performance of the coal. The lowest quality known as Type I. must evaporate in a locomotive boiler four and a half times its weight of water at a pressure of 90lb., and with a blast producing a reduction of pressure of 60mm. of water; the next better quality, known as Type II., must evaporate five and a half times its weight of water at the same pressure and draught; Type III. must evaporate seven and a half times its weight of water at 120lb. pressure, with a blast of 85mm.; and Type IV., the same efficiency, with a blast of 120mm. The Sambre Canal Company have made important reductions in their tariff for Belgian coal, and for products sent to collieries. Makers of briquettes in the centre and at Charleroi will be thereby enabled to obtain pitch from Paris under the most favourable conditions. In addition a rebate of 45 per cent., or about 1s. 3d. per ton, will be given on all shipments of briquettes.

THE METAL MARKET.—Prices on the whole are firm and the market is active, girders and angle iron being specially in demand. Merchant iron is quoted at 96s. per ton, girders at 96s., and No. 2 sheets at 120s. The price of Athus forge pig is 38s. 5d., and of the best Charleroi pig 43s. 2d. The rates for pig show some weakness, and the prices given above are only for urgent requirements. For future delivery reductions of 10d. to 1s. 8d. per ton are being made. Stocks are beginning to accumulate, and though they are small, the course of the market is nevertheless affected. A rise in the English market is the only thing which would have a counteracting influence. Some important orders for rolling stock for the Belgian State railways have been given out, the Dyle-Bacalan, Baume-Marpent, and Franco-Belge companies being the successful competitors. Old rails are quoted at 65s.

GLASS WORKS.—The convention for fixing the rates for the American market, which was concluded on the 1st of September last, was established for two years, but with power of bringing it to a conclusion on the 1st of July of this year. At a meeting of Charleroi glass makers, it has been decided to terminate the arrangement. This will cause fresh competition to our glass makers; but as manufacturers on the other side of the Atlantic had not been very strict in their observance of the convention, it will not make much difference.

TEXTILES.—The price of Russian hemp has risen about 1s. 8d. per cwt., and at Ghent there is far less being done than in the French markets. Home grown flax is quiet, but some important sales of Flanders yarn have been made. Owing to the bad prospects of this year's crop manufac-

Digitized by Google

turers are anxious to contract for part of their requirements. Prices, in consequence, are firm, and a rise is anticipated.

ELECTRIC LIGHTING AT THE EXHIBITION.—So far the most successful installation is that of the Thomson-Houston Company, comprising seventy-eight arc lamps, the next best being that of the Société Bouckaert-Schuckert. The Pieper system has proved the worst, and the Brush Company's has not made a favourable impression. This has been due to the inferiority of the engines employed. M. Pieper has used a Van der Kerchove twin engine, which runs irregularly, and the Brush Corporation an engine by M. Van Acker, of Brussels, which has proved equally unsuitable. The Thomson-Houston Company employs an Armington-Sims engine of 84 h.p., driving two dynamos of 45 and 42 lamps capacity respectively. This engine works very well. M. Pieper is going to adopt an Armington-Sims engine instead of his present one. Some small installations will probably yet be put up in and around isolated buildings in the gardens, the motive power being supplied from some engines in the galleries of the machinery hall. The internal lighting at the Exhibition is throughout very good. Messrs. Ganz & Co. show their transformer system in practical operation; and M. Khotinsky has a nice exhibit of incandescent lamps supplied by batteries. There is a fair display of different types of direct driven dynamos, with high speed engines.

GUNPOWDER.—The Royal Powder Mills at Wetteren are making a new kind of gunpowder, which gives similar results to the Lebel powder; it is called *poudre papier*, and its ballistic value is much higher than that of the ordinary infantry powder. With a charge of 2½grm. of this powder, a bullet fired from a small calibre rifle attained a muzzle velocity of 1970ft. The new powder does not foul the barrel, and produces very little smoke.

DÜSSELDORF, 25TH JUNE, 1888.

THE IRON MARKET.—The iron market is quiet, but firm. A better tone has appeared within the last few days, arising from the improving aspect of affairs in England and more favourable reports from the United States. Business in pig iron is still very slack. Stocks increased 5500 tons in the month of May. Judging from the amount of business now being transacted, there should be a larger accumulation by the end of the current month. The weekly output of pig is now very large, and imports are heavy. The demand for spiegel has further decreased. The 10 to 12 per cent. quality is now offered at 57s. Forge is but little sought after. Lower prices are accepted from foreign buyers. For Luxemburg forge, however, there is a stronger demand, and prices have advanced to 41s. Thomas pig is also in better demand, and prices have become very firm again. For Bessemer, the market is somewhat dull. Foundry is still in brisk demand. The finished iron trade exhibits a little more life. Bars and wire constitute dull features, but there is considerable animation in most other classes of goods. Joists are in brisk and increasing demand. It is not unlikely that an advance in price will be declared at the next meeting of the syndicate. Orders for plates continue to come in freely. The make of plates by the firms which are members of the syndicate amounted in May to 10,333 tons, against 9548 tons in the same month of last year; and the orders booked in the same time amounted to 9036 tons, against 7289 tons. Sheets are still neglected, and some manufacturers have begun to restrict the make. Founders are very busy, and great activity prevails in machine shops. The exports of machines, other than sewing machines, in the first four months of the current year amounted to 19,263 tons, against 17,777 tons in the corresponding period of 1887. The make of pig iron in the month of May amounted to 360,855 tons, against 327,282 tons in May of last year. The total production in the first five months amounted to 1,756,310 tons, against 1,527,721 tons in the corresponding period of 1887.

ZINC PRODUCTION IN SILESIA.—The weakening tendency of the market for spelter has directed attention to the production of the Silesian mines. The output in the first quarter of the current year amounted to 20,999 tons, against 20,478 tons in the same period of 1887. The deliveries in the first quarter amounted to 19,727 tons, valued at £315,164, against 16,805 tons last year, valued at £219,033. As the number of workmen employed has increased only from 6047 to 6269, the augmented value represents a wider margin of profit. The exports from the whole of Germany have decreased compared with last year, the quantities for the first four months being, for spelter and scrap zinc, 14,911 tons, against 15,934 tons, and for rolled zinc 3483 tons, against 5425 tons.

LILLE, 26TH JUNE, 1888.

TEXTILE MANUFACTURES.—The trade in textile goods remains on the whole dull and lifeless. There are fluctuations from week to week, which serve only to raise and depress the hopes of manufacturers. Little or no progress is made towards recovery. In linen goods, in which this district is chiefly interested, business has decreased compared with last week. We are certainly in the dead season, but the turnover is below the average. Cotton goods move heavily in the market. The woollen trade, too, remains quiet, no further improvement having taken place. In silk goods a fair amount of business is being done; but the market lacks life and buoyancy. The foreign trade shows some expansion relatively to last year. The declared value of the imports of textile goods in the first five months of the current year amounted to £2,743,680, against £2,728,560 in the corresponding period of 1887. The value of the exports in the same time amounted to £11,671,080, against £11,616,000 last year. These totals were made up as follow, the figures within brackets being those for 1887:—Imports: Linen goods, £91,040 (£86,960); jute, £29,760 (£31,680); cotton, £812,520 (£950,120); woollen, £890,440 (£877,920); and silk, £919,920 (£781,880). Exports: Linen goods, £142,720 (£130,080); jute, £40,920 (£37,960); cotton, £1,715,760 (£1,855,000); woollen, £5,884,400 (£5,817,160); and silk, £3,887,280 (£3,775,800).

THE FLAX AND YARN MARKETS.—There is now but little business doing in flax, either home grown or Russian. The heavy rains which have fallen have put an end to the speculative buying that infused life into the market a fortnight ago, but prices remain firm. There is still considerable activity in yarns. Spinners have plenty of orders on hand, and refuse to commit themselves far into the future. Prices are firmly maintained. More business is being done in hemp. Tows are specially in demand.

THE IRON MARKET.—There is no lack of activity in the iron market of this locality. On the contrary, the orders which come to hand, though individually of little importance, are sufficiently numerous to maintain a fairly strong and steady course of business. Yet some anxiety is felt in respect to the immediate future of the trade. The merchants of Paris are able to supply the present needs for the few manufacturers who remain outside the syndicate, and consequently they persist in depressing the market. The latest accounts received from other districts are not encouraging, and the political outlook is clouded. For the present prices remain firm. At Valenciennes there is a brisk demand for steel billets, while at Denain there is great activity in the works making metal sleepers.

AMSTERDAM, 26TH JUNE, 1888.

THE PORT OF ROTTERDAM.—The yearly statistical review of the Port of Rotterdam has just been published, and is, as usual, full of varied information. In 1887, 4153 steam and sailing vessels, of a total of 2,488,264 tons, entered the port. Compared with 1886, this is an increase of fully 10 per cent. The figures show that Rotterdam is, in commercial importance, the eighth port of Europe, and its shipping is only a little under that of Hull and Antwerp. The report states that last year 7272 steam and 1547 sailing vessels of 14,528,943 tons, in addition to 3640 fishing boats, used the new waterway. These totals show a considerable increase compared with those of 1886. The framers of the report mention that the new waterway or ship canal from the sea to Rotterdam is being improved, and answers its purpose very well, for the time being; but they point out that the tendency everywhere is to increase the depth and width of ship canals and the accommodation of harbours for ocean-going craft. The minimum depth of the Rotterdam waterway at low water will only average 65 decimetres, whilst Havre will have, under similar circumstances, a depth of 80 decimetres, as soon as its Harbour Act is carried out. The Chamber of Commerce at Rotterdam urges that the minimum depth of the ship canal to the Hock of Holland ought to be increased to 80 decimetres, thus enabling the largest ocean steamers to proceed to Rotterdam.

NATIONAL INDUSTRIAL ART EXHIBITION.—An exhibition has been opened this month near the Hague. The exhibits comprise an extensive collection of industrial art products. The principal cities of Holland have contributed to this Exhibition. A congress of Dutch manufacturers, promoted by the Dutch Society for Industry, will be held at the Hague from the 9th to the 13th of July next, in which various questions relating to national and international manufactures are to be discussed.

WINTERTHUR, 25TH JUNE, 1888.

COAL.—The annual imports of coal into Switzerland average £720,000 in value. Attempts have been made from time to time to find coal here, but without result. The last large undertaking with this object, which sunk shafts in the canton of Aargau, lost thousands of pounds; but a new syndicate has now been formed in Zurich to bore for coal in the neighbourhood of Cornol, in the Bernese Jura. It is considered certain that a bed of coal extends from the Vosges, through the Jura mountains and the Swiss plateaus, to the Alps. For the most part the depth, viz., 5000ft., is too great to allow of its being worked profitably; but in certain portions of the Jura the depth is only 2000ft. It is intended to sink shafts to reach these latter strata, and if the experiment is successful it will bring about a revival of the iron industry in the Jura.

EXPORT TRADE.—The Geneva watch making industry has been very active for some months past, and large orders are received from America. The value of the textile goods exported to the United States in May from St. Gall, which is the centre of machine embroidery, shows an increase of 25 per cent. compared with the same month last year, the total value being in round numbers £63,000.

RAILWAY BRAKES.—The Gothard Railway, after experimenting for some time, have decided to adopt the Westinghouse automatic brake on their system. The same brakes are also being employed on the North-Eastern, Central, and Western railways of Switzerland.

BICYCLES FOR THE ARMY.—At the last military manœuvres the system of employing bicyclists for carrying dispatches was found to work so well, that cyclists will permanently form part of the army corps. This has given an impetus to the manufacture of bicycles in Switzerland, and the Government engineering shops at Thun have now taken up this branch of manufacture, and supply bicycles for military purposes.

NEW YORK, 16TH JUNE, 1888.

IRON AND STEEL.—The annual report of the American Iron and Steel Association states that the production of pig iron in the United States during 1887 was 6,417,148 tons, against 5,683,329 tons in 1886, an increase of 13 per cent. Of this 60 per cent. was made with bituminous coal and coke, 26 per cent. with coke and anthracite, 6 per cent. with anthracite, and 7 per cent. with charcoal. The production of Bessemer and Clapp-Griffiths steel amounted to 2,936,033 tons, an increase of 29 per cent. Eight new Bessemer and three new Clapp-Griffiths plants were completed in 1887, and at the close of the year there were altogether forty-three Bessemer plants with eighty-nine converters. The production of steel rails was 2,049,638 tons, against 1,526,410 tons in 1886, and 959,471 tons in 1885.

THE EDISON PATENT CASE.—The decision of Judge Wallace in the suit of the Edison Electric Light Company *versus* the United States Electric Lighting Company has attracted considerable interest amongst electricians here, and is important because affecting generally a point in the American Patent Law on which opinions have hitherto been divided. The United States Electric Lighting Company are antagonists of old standing of the plaintiffs, and have never shirked legal proceedings, but rather invited, or at least facilitated, the bringing of actions against them, so as to define their legal position with regard to certain patents. In the present case they were accused by the Edison Company of having infringed a certain patent for improvement in dynamos, which Edison applied for in America, in August, 1880, and in Austro-Hungary shortly after; but which, owing to the slow procedure of the United States Patent Office, was granted and published there a considerable time after the issue of the Austrian patent. The defendant company did not enter into the technical question whether they had or had not infringed, but relied solely on the fact that the Austrian patent had been allowed to drop in 1883, and that, therefore, the American patent was also no longer in force. The point at issue was whether the clause which makes the continuance of a United States patent depend upon that of any anterior foreign patent, should also apply to the present case, where the application for a United States patent had been made before any application for foreign patents. According to Judge Wallace, the clause also applies to such cases, so that in the future American patents, notwithstanding priority of application, will only remain valid as long as any foreign patent for the same invention remains in force. The practical effect of the verdict gained by the United States Electric Lighting Company in this suit is to throw open for public use not only the patent in question, but many others of Edison's patents, which have been taken out and then dropped in foreign countries.

NEW ELECTRIC RAILWAY.—Hitherto electric railroads started in this country were almost exclusively for passenger traffic; but a new line, the Ansonia, Birmingham, and Derby Electric Street Railroad, which was opened a fortnight ago, is mainly intended for goods traffic, although it does also carry passengers. The line is built on the Van Depoele system, and is in the form of the letter **Y**, the right arm of which runs to Ansonia, whilst the left crosses the Naugatuck river to Birmingham, and the stem leads to Derby dock, where the generating station is established. The river is not navigable above Derby, and the large factories of Ansonia, some three miles above the docks, could therefore not directly be reached by the Naugatuck Valley Steamboat Company running steamers from New York, and the goods traffic to New York went mostly by rail. The new electric road is intended to divert this traffic into Derby, and thus benefit the steamers. The line is operated from an overhead wire 380mils. diam. suspended about 16ft. above the street level from cross wires stretched between poles on either side of the track, a pair of poles occurring about every 100ft. The return current passes through the rails, which are of the ordinary tramway pattern, but joined by special copper fish plates. The current is taken off the wire by means of a grooved wheel pressing upwards against the wire, a swivel arm and spring attachment giving the required flexibility to the system. At the generating station within the Derby dock there is a 100 h.p. engine and boiler, and an 80 h.p. dynamo, and the motors used on the cars are of 15 h.p.

NEW RAILWAY.—A new system of railway has been invented by Mr. E. M. Boynton, who indulges in the very modest expectation of running trains on it at the rate of 100 miles an hour. The railway has one track laid on the ground and another directly over it, carried on a frame work. The locomotive and cars have wheels on the bottom and on the top, so as to make derailment impossible. The locomotive, which is now being built in the shop of Messrs. Russell & Sons, of Newburyport, Mass., has a single driving wheel 8ft. in diameter, and cylinders 12in. diam. and 14in. stroke. The boiler is 13ft. long and 42in. diam. All the wheels are of cast steel, with deeply flanged tyres shrunk on. The seating capacity of the train will be for one hundred passengers, and the first experiments are expected to take place in next August.

THE EASTERN ARSENAL OF TIENTSIN.

By Allan C. Wylie.

II.

New Powder Mills.—These mills have been recently erected on the south and west sides of the Arsenal grounds, as far apart from the other buildings as possible, and comprise: (1) A brick building containing a charcoal breaking down machine and two pulverising drums; two nitre pulverising drums and two sulphur ditto. (2) Two buildings, each containing two mixing drums. (3) Two buildings, each containing two incorporating machines of the usual edge runner type. (4) One building containing one breaking down machine and one powerful hydraulic press and set of pumps. (5) One building containing one corning frame, the rolls being made of gun metal, with saw teeth, one roller being driven at double the speed of the other; from the corning rolls the powder is fed into two hexagon wire-covered reels, working on a slope, the wire cloth varying in the size of mesh to suit the various sizes of grains required. (6) One building containing two dusting reels, also of hexagon form, by which the superfluous dust is removed, and the grains again separated into their various sizes. (7) One building containing two glazing drums of cylindrical form made of oak. (8) One building containing two prismatic machines, which compress the powder into hexagon prisms about 3·4cm. in diameter by 2·4cm. in thickness, with a central hole about 93mm. in diameter. These machines are worked by eccentrics, with a movable feed plate, and are more complicated and consequently more liable to derangement than similar machines worked by hydraulic power. The whole of these machines are of German manufacture, as are also the engines, boilers, and gearing by which they are driven. The engines are a pair of coupled horizontal condensing engines with cylinders about 16in. diam. and 3ft. stroke, steam jacketed, with a peculiar expansion valve automatically actuated by a complicated arrangement of governor; but, in my opinion, a long way behind the best examples of the same class of engines made in England. The fly wheel is grooved to carry twelve ropes 6½in. in circumference, and the power is transmitted by rope gearing to the various buildings enumerated. The boilers supplying steam to these engines are three in number, placed in a building about 250ft. distant from the engines, and this distance must cause considerable loss by condensation. They are constructed on the principle of the Root's boiler, but have "Schwartzkopff's Patent" on the name plate. They are marked 10 atmospheres (150lb.), which, I presume, is the limit of their working pressure.

Drying Stove.—This is placed about the same distance from the boilers as the engines, but in the opposite direction, and the necessary heating power is conveyed to them by pipes and reducing valves.

Powder Proof Range.—This is situated in the eastern part of the grounds, and comprises an Armstrong 12lb. breech-loading gun, of the newest design, mounted on a beautiful flanged steel field carriage, the wheels of which are exceedingly well made and finished. It is fitted with a crusher gauge and the necessary apparatus for recording the muzzle velocity by one of Le Bulengé's chronoscopes, which is placed at a convenient distance from the firing range, and electrically connected with it. The strength of the powder manufactured is here carefully tested and tabulated by a very intelligent Chinese officer, who has been educated in the United States. I also noticed a densimeter, made by Elliott Brothers, London, consisting of a barometer tube with air pump attached, for ascertaining the density of the powder.

Drawing Office.—In this department there are about twenty young Chinese students, who all seem to be well educated. They are studying mechanical drawing and engineering, so as to qualify themselves for positions as foremen and managers of the various departments.

General Remarks.—The wages paid to the best workmen range per month from $15 to $20; ordinary workmen, $5 to $9; boys, $1½ to $3; coolies or labourers, 150 cash per day (about 7½d.). Work commences at 7 a.m. and finishes at 5 p.m., with an hour for dinner, and is carried on every alternate Sunday. The men seemed very industrious, quiet, and contented. Every department appeared to be carefully conducted, the machinery and shops were kept in first class order, and notwithstanding the dangerous nature of some of the processes enumerated, very few accidents have occurred since the works were commenced. The number of workmen at present employed is about 1500, all of whom, with their managers and foremen, are Chinese; the only European connected with the Arsenal being Mr. J. Stewart, the chief engineer, who has had the superintendence of erecting and starting the various departments I have named, with the assistance for short periods of Europeans sent out by the makers of the various plants, who also instructed the natives in the manufacture of ammunition, cartridges, &c. Mr. Stewart seems to have thoroughly and deservedly secured the confidence of the Chinese Government by the energetic and scientific manner in which his onerous and varied professional duties have been carried out. In the whole of this extensive establishment I did not see a single soldier or policeman; but attendants are stationed at the gate, as at Woolwich Arsenal, to see that nothing is taken away as the men leave work. Very little wood working machinery is used in the Arsenal, as the wages of coolies—who are excellent timber sawyers—are so low, viz., about 7½d. per day. Cannon, rifles, small arms, steel shells, or gun carriages are not made here; but it is evident from what I have seen that these departments will, one by one, be added at no distant period. An abundant supply of good coal is obtained from the Kaiping mines, about ninety miles distant; from which, as already mentioned, a branch from the new railway will be laid into the Arsenal.

Imperial Naval College.—On the eastern side of the Arsenal grounds, but kept totally distinct, are erected a series of buildings, called the Imperial Naval College, which is under the direction of the Taotai Lü, a member of the Hanlin College, which is the highest literary rank to which a Chinese can attain. The College is divided into two parts, the executive and the engineering. The former is under the control of Mr. Yen, a Chinese naval officer, who has graduated at the Royal Naval College, Greenwich, and has seen considerable service afloat. His staff has recently been reinforced by Mr. W. McLeish, B.A., formerly of Dulwich College, London. The studies in this department comprise mathematics, navigation, and nautical astronomy; and from the number of observations made during each twenty-four hours, I think that the latitude and longitude of this part of the world ought to be deeply impressed on every student's mind. Each student, before being admitted into this College, must pass a severe examination in Chinese classics, which also continues to form an important feature of his studies during the whole of his term. At the time of my visit, a batch of twenty-four students had just completed their course of instruction, and were about to take up their appointments in the steamers of the Imperial northern fleet, called the Pei-Yang squadron. The usual number of students in this department is about sixty, and the lessons are all given in English, the study of which begins as soon as they enter the College. I examined the engineering department with great interest, every facility for so doing being given me by Mr. H. W. Walker and Mr. G. H. Hearson, both of them engineers of the Royal Navy, who have been specially selected and lent by the British Government to fill their important positions. After being introduced to the courteous Chinese official in charge of this department, Mr. Kan, who welcomed me with true Chinese hospitality, I first paid a visit to the junior class of this department, and on the invitation of the Chinese instructor, I proceeded to question them on some elementary subjects. These students had been in the College about a year; their studies having been limited to acquiring a knowledge of the English language, elementary arithmetic, algebra, geometry, and geography. Considering the short time they had been engaged in these studies, and in a language totally dissimilar to their own, I was much impressed with the fluency displayed in reading English, and in solving problems in Euclid in the same language, asked at random. In describing on a black board the circles necessary to elucidate the problems, I was much amused by the ingenuity displayed in drawing these circles without the aid of compasses. Taking his long plaited queue in his left hand, and adjusting the radius with a small piece of chalk in his right hand, the student swept the circles with a rapidity and accuracy which seemed almost to foreshadow that the use of compasses in China would be found absolutely unnecessary.

At the time of my visit the senior class of students were engaged in the workshops connected with the College, and a brief description of these may not be uninteresting. These consist of a large and commodious fitting and turning shop 140ft. long by 40ft. wide, in which are erected a well selected plant of tools, consisting of turning and screw cutting lathes, planing, shaping, slotting, and drilling machines, &c., with benches and vices to correspond. The students are here instructed in the various uses of these tools during three days per week, the remainder of the time being devoted to theoretical studies. In this shop I was much pleased with the cleanliness and good order in which everything was kept, showing the care with which the early training of their English instructors had been impressed on their pupils. Adjoining this shop are the pattern, smithy, and moulding shops, in which all these branches are carefully and practically taught. These workshops have been in operation about three years, and were designed and carried out by the English instructors already named. In the interesting torpedo department, which is under the direction of Mr. Hearson, are two vertical engines and air compressors, made by the General Engine and Boiler Company, London, and a good supply of torpedoes. Those I saw are constructed on the Schwartzkopff principle, with phosphor bronze air chambers, and gun metal shells. The students are instructed to take these asunder, fit them together again even to the most minute and accurate details, and make the necessary adjustments. Close at hand is a wharf, from which dummy torpedoes are launched into an adjoining creek. Round the walls of this department are a series of well finished drawings and sections of all parts of the torpedoes, made by the students themselves. All the various working drawings have been made by the students under the supervision of their instructors, and reflect great credit on both masters and pupils. I looked over a set of marine engine drawings made by one of the students, and examined him as to the names of the various parts, their uses, and what materials they were made of, and I was certainly surprised at the rapidity and correctness of his replies—all given in English. The normal number of students in the torpedo department is about sixty. The whole of the students in the College are drilled daily for an hour, on the German military principle, and the senior students make excellent rifle practice. There is also a ship's mast and rigging on the grounds, on which they are exercised; but a good gymnasium, similar to those in use in all naval and military colleges, would still more improve their mental and physical capabilities. All the students are lodged, clothed, and fed at the Government expense, and receive pay varying from three to eight taels (15s. to 40s.) per month, according to their qualifications and seniority. The College and students are personally inspected at least once a year by His Excellency the Viceroy, Li Hung Chang, who takes a great interest in this institution, and to whose enlightened policy much of its success is due.

These students, as they finish their education and enter the Chinese navy, will no doubt exercise a great influence on their fellow countrymen, not only on board ship, but throughout every part of China; as what they have been taught in this College, and what they have learned personally of Europeans and their habits and customs, must form the theme of many an interesting discourse at their own homes, and from there permeate every class of Chinese society, down to the hardest working coolie. A great and ancient nation like the Chinese cannot be altered to new methods of thinking, teaching, and working in a short period, and it is only by such institutions as I have endeavoured to describe that it can be leavened and raised in the scale of nations. Baron von Richthoven, who has personally explored fourteen provinces of China, states that no province is wholly without coal; but the chief deposits are in the southern half of Chan-si, in the south of Human, and in the west of Chan-ting; and that the coal seams of Chan-si alone cover an area of not less than six hundred square miles, and contain 730,000,000,000 tons, the quality being an excellent anthracite; and that in the south-east of the same province there is another basin nearly as large, containing coal of a more bituminous character, which is already largely worked. The total annual consumption of coal of the world being taken at about 300,000,000 tons, there is therefore enough in the southern part of Chan-si alone to supply the demand of the whole world for probably 2000 years. Therefore, when similar arsenals and colleges to those I have described have been established in the various provinces of this immense empire, coupled with a complete system of railways—the one now in course of construction to this city being, without doubt, the forerunner of others in the near future—and with such a coal supply as I have indicated, China, with its great resources and cheap labour, will then begin to take its proper position among the nations of the world.

LIFE SAVING AND PRESERVATION CONGRESS.

The third meeting of the French Congress for the Preservation and Saving of Life will be held from the 25th to the 30th September next in the Palais de L'Industrie, Paris. The central portion of this large building will be converted into an immense lake, having a surface of about 5470 square yards. On this lake will be represented the various systems of lifeboats in use on the French coasts. In another basin, which will be erected with transparent walls so that it may be possible for visitors to see the interior of the basin, there will be shown at intervals divers engaged at work on an imaginary wreck. The questions which the Congress will consider are divided into the following ten sections: (1) Accidents which take place from natural causes, such as are due to the atmosphere, inundations, earthquakes, &c.; (2) the cause of epidemics and the means of their prevention; (3) the best means to be adopted for the prevention and extinction of fires; (4) the prevention of shipwrecks, the lighting of the coasts, and the erection of lighthouses; (5) the measures to be taken for the medical and surgical treatment and accommodation of wounded soldiers in time of war; (6) the means to be adopted for the prevention of accidents to persons engaged in dangerous occupations, such as those working in pits, in compressed

Digitized by Google

air, water, &c.; (7) accidents occurring to persons travelling in railway trains, tramways, carriages, on board ship, &c.; (8) the best measures to be adopted for helping persons injured by accidents which render them incapable of providing for themselves and their families the necessaries of life; (9) the means to be taken for assisting persons wounded in the streets by falls, blows, bites of insects, &c.; (10) domestic accidents, their prevention and alleviation.

SHIPBUILDING NOTES.

Messrs. Jos. L. Thompson & Sons, North Sands shipbuilding yard, Sunderland, launched on the 23rd inst., the handsomely modelled steel screw steamer "Enterprise," built to the order of Messrs. Marwood & Co., of Whitby, and sister vessel to the "Discovery," launched on the 9th inst. by the same builders for the same owners. These vessels have a deadweight capacity of about 3000 tons on a light draught, and are of the "well deck" type. The engines, which have been constructed by Messrs. Thos. Richardson & Sons, West Hartlepool, are of the triple expansion type, and the working pressure is 150lb. per square inch.

The steamer "Dotterel," belonging to the Cork Steamship Company, went for her official trial trip last week after having her machinery converted to the triple expansion type by Messrs. David Rollo & Sons, of Liverpool. The cylinders are now 20in., 32in., and 52in. diam. respectively, with a stroke of 36in. There are two new steel boilers, 12ft. 6in. diam. by 9ft. 6in. long, each being fitted with three of Brown's patent ribbed furnaces, 3ft. 11in. diam. With a steam pressure of 150lb., at 74 revolutions per minute, 875 h.p. were indicated, the vessel running an average speed of 11 knots per hour. The improvements have resulted in an increase of speed with a reduction of fuel.

The steamer "Quito," just completed for the Pacific Steam Navigation Company by Messrs. Laird Brothers, of Birkenhead, made her official trial trip in Liverpool Bay last Saturday. With the engines running at 90 revolutions per minute, steam at 155lb. per square inch, upwards of 900 h.p. were indicated, and the vessel ran about 13 knots per hour on the measured mile. The vessel is 225ft. long, 35ft. broad, and 22ft. 6in. deep; and is the twelfth vessel Messrs. Laird Brothers have built for the Pacific Steam Navigation Company.

On the 19th inst., Mr. C. J. Biggar launched from his shipbuilding yard, Londonderry, the "Ivy," a handsome screw steamer for Messrs. A. A. Laird & Co., Glasgow, for their Londonderry and Glasgow cross channel trade. The dimensions of the vessel are: Length, 200ft.; breadth, 28ft.; depth, 13ft. 6in. She is built of steel, beyond Lloyd's requirements. There is poop accommodation for sixty first class passengers, and a handsome smoking room and companion on the poop deck. The forecastle is fitted for steerage passengers, and the holds between decks for cattle. Electric light will be fitted throughout.

On the 25th inst., the passenger steamer "Gulf of Corcovado" was launched from the yard of Messrs. R. and W. Hawthorn, Leslie, & Co., Hebburn. The vessel has been built for the Greenock Steamship Company. The length of the vessel is 320ft.; breadth, 40ft.; depth, 25ft.; having long poop, long bridge, and topgallant forecastle. She is built of Siemens-Martin steel, and will class 100 A1 at Lloyd's, and to gain the Board of Trade passenger certificate. She is the first of four vessels building by Messrs. Hawthorn, Leslie, & Co., for the Greenock Steamship Company, for their Gulf Line of steamers, and is intended for their South American trade.

The "Alexandra," built by Messrs. McKnight & Co., Ayr, for the Alexandra Towing Company, Liverpool, was launched on the 22nd inst. The "Alexandra" is an iron screw tug, 92ft. by 20ft. by 12ft. The engines, which are of 30 h.p., are by Messrs. Muir & Houston, Glasgow.

The "Oriole," paddle steamer, for the passenger service of the General Steam Navigation Company, London, was recently launched from the yard of Messrs. John Scott and Co., Kinghorn. The dimensions of the "Oriole" are as follow: Length, 236ft.; breadth, 27½ft.; and depth, 10ft.

The paddle steamer "Princesse Henriette," built to the order of the Belgian Government, and recently launched from the ship yard of Messrs. William Denny & Brothers, of Dumbarton, went on her official trial on Friday, the 15th inst., when most satisfactory results were obtained. The mean speed obtained during the trial was 21·1 knots, being six-tenths of a knot in excess of the requirements. The "Princesse Henriette" is a two-bowed vessel, 300ft. in length, 38ft. in breadth, and 13ft. 6in. moulded depth. She is fitted with a rudder forward as well as aft, to enable her to leave the harbour at Ostend without having to turn inside it. The stipulated draught of water was not to exceed 8ft. 8in.; but the builders have succeeded in keeping well within these limits, and the actual draught is much less. The engines are on the compound principle, having two cylinders of 59in. and 104in. respectively, with a stroke of 6ft.; the slide valves are worked by Brock's valve gear. On Thursday, the 21st inst., the "Princesse Henriette" made the quickest passage on record between Ostend and Dover, the time occupied being 2 hours and 50 min., which is less than the time taken by the steamers now on regular service by 1 hour and 50 min.

Notices of Meetings.

NEXT WEEK.

ROYAL INSTITUTION OF GREAT BRITAIN.—Monday, 2nd July, 5 p.m. General monthly meeting.

ROYAL UNITED SERVICE INSTITUTION.—Friday, 6th July, 3 p.m. Paper to be read on "The Machinery of Modern War Ships," by Mr. H. J. Oram, Engineer, R.N.

GEOLOGISTS' ASSOCIATION.—Friday, 6th July, 8 p.m. Papers to be read on "The Rhætics and Lias of Glamorganshire," by Mr. H. B. Woodward, F.G.S.; on "The Geology of the Forest of Dean," by Mr. E. Wethered, F.G.S., F.C.S.; and on "The Clays of Bedfordshire," by Mr. A. C. G. Cameron, of H.M. Geol. Survey.

PRICES CURRENT, 28TH JUNE.

Quotations at per ton, unless otherwise specified.

Messrs. S. W. Royse & Co., Manchester, report as follows:—

A better feeling exists in the chemical markets generally. Bleaching powder is pressed for sale at lower figures. The demand for soda ash is regular, and values practically unchanged. Caustic soda is also in fair demand at steady prices. Carbolic acid continues to weaken. In acetate of lime rather more has been doing, but prices tend downwards. In sulphate of ammonia a fair amount of business is being done at steady prices. Muriate of ammonia is in good demand, and acetate of soda is strongly inquired for.

MR. ROWLAND WILLIAMS, F.I.C., F.C.S., Manchester, has removed his chemical laboratory from Albert Square to larger premises at 28, Pall Mall, Manchester.

TRADE CATALOGUES.—We have received from Messrs. Lancaster & Tonge, Pendleton, near Manchester, a copy of their new catalogue, which contains illustrated particulars of steam engines, pumps, injectors, screwing machines, and other apparatus manufactured by the firm. They also issue a smaller price list of their leading specialties.—Messrs. Archibald Smith and Stevens, Queen's Road, Battersea, S.W., in a catalogue just sent out give a complete illustrated list of lifts of all kinds.—We have also received from Messrs. George Richards and Co., Limited, Broadheath, near Manchester, a complete and neatly illustrated catalogue referring to Richards' automatic cut-off engine. The illustrations show general views of the complete engine and all important details, while the description explains the advantages claimed by the makers. A number of indicator diagrams are given in order to illustrate the perfect regularity of the automatic cut-off under varying conditions of load. In perusing this catalogue, the reader will find some novel and interesting departures in the design of the engines.

NEW ENGINEERING WORKS AT BURY.—Messrs. John Downham and Co., Bury, are commencing the erection of an iron works, which is to be called the Barn Brook Iron Works. The main buildings will be 150ft. long and 50ft. wide, and will be constructed from the materials which formed the east nave of the Manchester Exhibition. Employment will be found for 150 hands, who are to be engaged in the making of all kinds of machinery used by dyers, bleachers, finishers, and calico printers. A large travelling crane, 35ft. span and 24ft. high, is to be used for facilitating the transit of work to a number of heavy lathes, planing, slotting, and radial drilling machines; and the part of the building which is not surmounted by the crane will be covered by a gallery, where the construction of light machinery will be carried on. The general arrangement comprises all the most modern advantages, and the tools, which are of the latest designs, are being made by Messrs. Kendal & Gent, Messrs. Hulse & Co., Messrs. W. Muir & Co., and Messrs. Vaughan & Sons. A steam boiler to work at 100lb. pressure is being supplied by Mr. W. Lord, of Bury, and a horizontal condensing engine by Messrs. John Musgrave & Co., of Bolton.

RAILWAYS.—A project is on foot to establish a circular railway for the town of Buda-Pesth. As the Hungarian Minister of Communications is taking very active steps to push this matter forward, it is probable that Buda-Pesth will be provided with a railway of this kind before a similar one is constructed in Vienna.

HOME INDUSTRIES.

MANCHESTER, 28TH JUNE, 1888.

THE ENGINEERING TRADES.—There is no scarcity of work in the general engineering trade, and constant employment is found for all classes of mechanics. The reports of the various trade societies are unanimous in the assertion that work is plentiful, and that the number of unemployed is very few. Stationary engineers continue to be fully supplied with orders, and there appears to be no probability of any falling off. Many large orders are being executed on Indian, Russian, and Japanese account, and these, together with the constant run of home orders and repairs, are sufficient to keep the works in full operation. It is also stated that prices are gradually rising, although they are still much below the limits at which the engineers think they should be fixed. Millwrights and boiler makers continue to be well employed. The recent fall in steel boiler plates has not helped the makers to any great extent, on account of their having been covered with contracts. The fall will probably lead to a corresponding drop in the price of steel boilers. Bridge and girder makers are busy with a considerable number of orders which are now in course of execution. Machine tool makers continue to improve. There is a better demand for railway tools, especially on Indian and Colonial account. Machine makers are fully occupied, and from all parts of the world orders are coming in freely. Some firms in this branch of industry are paying special attention to the Eastern markets, notably China and Japan, and it is reported that their efforts have been very successful. In spite of the high tariff, large consignments of textile machinery are being shipped to the United States. The replacement of preparation machinery continues, so that whole departments are kept busy from this cause only. The new opener grid recently introduced by Messrs. Crighton and Sons, of Manchester, has an extensive sale, and is giving good results in practice. In carding engines a large number of the old type of roller and cleaner machine are being made, especially by Messrs. Platt Brothers & Co., Limited, Messrs. Asa Lees & Co., Limited, both of Oldham, and Mr. John Mason, of Rochdale. Mr. John Tatham has begun to make a patented arrangement for grinding the wire on the flats of revolving flat carding engines. This device grinds the flat while its working face is pressed against a plate, which is stepped to correspond with the heel, so that the points of the wire are kept parallel with the foundation, while at the same time its relation to the working face is kept unchanged. This is an important point in connection with these machines, and Messrs. Tatham & Knowles' invention meets it thoroughly. Loom makers are still busy, but new orders on home account are not coming in so fast as they were, although a good business is still being done with abroad.

THE SHIP CANAL.—The works in connection with this great undertaking are being pushed on, and are in many cases well forward. Railway communication is now established throughout the whole work, so that its progress is materially assisted. Near Manchester the waters of the Irwell have been diverted and conducted through a new cut, instead of through an old bend. The old bed of the river is being used as a spoil bed. An extensive landslip has occurred at Ince, but beyond a temporary disturbance of the works no damage was done. In connection with this work it may be pointed out that, as an indirect consequence of it, a good deal of engineering work will be required in carrying out the numerous sewage works which will become necessary to prevent the fouling of the river water. Several schemes are now on foot, including a large one of the Manchester Corporation, and several others will in a short time have to be commenced.

SMOKE PREVENTION.—Attention has been called in the report issued under the Alkali Works Act by Mr. Fletcher to an apparatus invented by Mr. Mond, of Northwich, for the production of gas from fuel which is quite smokeless when burned. The chief merit of Mr. Mond's process lies in the fact that the ammonia may be extracted before combustion in considerable quantity. It is stated that the experience of eighteen months' working is eminently satisfactory, and over 200 tons of fuel are daily treated in this manner at the works of Messrs. Brunner, Mond, & Co.

LONDON, 28TH JUNE, 1888.

THE MONEY MARKET.—The requirements of the Stock Exchange in connection with the settlement have made very little impression on the money market; the market continues dull and featureless, and rates remain at an almost unprecedentedly low ebb. The stock markets have more life and vigour in them, and at the close of last week the feeling was very strong, as there was a decided rise in foreign securities and in home railways. The strange thing about this was that the improvement was more marked in second and third rate than in first rate stocks. Russian, Turkish, Egyptian, and Greek Stocks gained perceptibly under the influence of Berlin buying. This to a large extent is due to the favourable view that is taken of the political outlook since the accession of the Emperor William. It is true that his speech to the Reichstag at the beginning of the week was followed by a decline in the markets; this, however, was due to a desire to realise the profit of the preceding rise before the beginning of the new account. The same occurred in the home railway market, the decline being entirely due to selling for realisation, and not to a want of backbone in the market, or to an unfavourable view of the prospects of the railways. Great Northern stock is considered to be the most promising purchase for the next week or two; and in the foreign market, which is generally healthy, Greek bonds are expected to mark a considerable gain in price. The American railway market is still hesitating, and will remain so until after the beginning of July, when the action of some of the prominent lines with regard to their dividends will decide the future tone. In the mining department diamond shares are unsteady, and copper shares tend downwards.

COMPANIES.—The following new companies have been registered since our last report: William Hunt & Sons, Ld., with a capital of £100,000, to carry on business as engineers and smelters at the Brades Works, Rowley Regis, at Oldbury, and at Birmingham; F. Joyce & Co., Ld., with a capital of £60,000, to carry on business as ammunition manufacturers; The Commercial Mill Company (Clayton-le-Moors), Ld., with a capital of £15,000, to carry on business as cotton and wool spinners; The Deanhead Water Company, Ld., with a capital of £10,000; The Langford Manganese Company, Ld., with a capital of £10,000; The Pottery Machine Company, Ld., with a capital of £27,000, to acquire patents for earthenware printing, &c.; H. Spicer & Co., Ld., with a capital of £150,000, to carry on business as paper manufacturers; The Honduras Company, Ld., with a capital of £25,000, to take over a concession for the Inter-Oceanic Railway of the Republic of Honduras; More & Co., Ld., with a capital of £70,000, to carry on business as brewers, &c.; The Martinstown (Dorchester) Brewery, Ld., with a capital of £15,000; The Condal Water Company, Ld., with a capital of £80,000; Suter, Hartmann, and Rahtjen's Composition Company, Ld., with a capital of £140,000, to carry on business as manufacturers of paints and compositions; The International Engineering Company, Ld., with a capital of £5,000, to acquire inventions relating to electric motors, &c.; The Algeciras (Gibraltar) Railway Company, Ld., with a capital of £750,000; J. & J. Charlesworth, Ld., with a capital of £500,000, to carry on business as colliery proprietors; The International Breweries Company, Ld., with a capital of £60,000, to carry on business as brewers in France; The Templeton and North Ottawa Mining Company, Ld., with a capital of £50,000; The Quebrada Copper and Silver Mines, Ld. (Nevada), with a capital of £4,000; and The Morgan Gold Mining Company, Ld., with a capital of £210,000.

TEXTILES.—The third series of Colonial wool sales opened on Tuesday last week. The attendance has been good, and the bidding brisk. Rates show a tendency to advance slightly. For Russian hemp higher prices are asked, but buyers hold back. A moderate amount of business has been done in Italian and in Manilla hemp.

RAILWAYS.—The gross receipts of the twenty-three principal railways in the United Kingdom for the week ending 17th June, amounted to £1,259,082 on 15,861½ miles, as compared with £1,242,546 in the corresponding period of 1887, when the mileage was 15,746 miles. An increase is thus shown in the mileage of 115½ miles, or 0·7 per cent., and in the receipts of £16,536, or 1·3 per cent.

ROYAL AGRICULTURAL SOCIETY.—The Royal Agricultural Society's show will open at Nottingham on Monday, 9th July, and the implement yard can be viewed on the previous Saturday. The show ground is by the side of the Nottingham Canal, with the main entrance from Derby Road. The implements and machinery will be arranged as usual in three rows of sheds, the machinery in motion occupying the right and left boundary of the show ground.

LECTURES.—A course of lectures on the construction, testing, and use of electrical measuring instruments will be given by Professor Ayrton at the Central Institution of the City and Guilds of London Institute, commencing on the 16th of July next. The course will include experimental lectures and laboratory work, the latter being carried on in a laboratory specially fitted with accumulators, standard instruments, &c., for testing electrical apparatus.

THE PATENT OFFICE.—A fifth report of the Comptroller-General of Patents, Designs, and Trade Marks for the year 1887 has been published, from which we learn that the total number of applications last year was, for patents, 18,051; for designs, 26,043; and for trade marks, 10,586. These figures are considerably higher than the average of the previous three years. Of the applications made during the year, 53 per cent. were proceeded with. The total receipts were £124,279, of which £105,599 were for patent fees.

EXHIBITION.—An Ironmongers, Iron and Metal Trades' Exhibition is to be held in the Agricultural Hall, Islington, in November next. The exhibits are to include household ironmongery of all kinds, lighting, heating, and sanitary appliances, machinery, implements, and tools. The Exhibition is promoted by Mr. H. Hetherington, who has had considerable experience in the organisation of similar undertakings.

GLASGOW, 28TH JUNE, 1888.

ENGINEERING.—The *Evening Citizen* reports that Messrs. Hanna, Donald, & Wilson have contracted for a number of iron railway bridges in Manilla. There are about 3000 tons of malleable and cast iron in the contract, which is to be implemented by the end of the year.

SHIPBUILDING.—It is reported that Messrs. A. Macmillan and Sons, of the dockyard, Dumbarton, have secured an order to build a small screw steamer for foreign owners. It is also reported that a steel screw yacht of 200 tons is to be built for an English gentleman by Messrs. Russell and Co., Port Glasgow. There is a rumour, understood to be well founded, that the Peninsular and Oriental Company have placed a very large order with Messrs. Laird & Co., Greenock, viz., four vessels, each of 5000 tons.

NEW ORDERS.—Messrs. Wm. Simons & Co., of Renfrew, have received an order from the Natal Harbour Board, for one of their patent hopper dredgers. This vessel will be specially designed to meet the requirements of the Port of Durban, and will have a hopper capacity for 500 tons of dredgings. It is to be fitted with the builders' patent traversing bucket ladder.

PIG IRON.—In the presence of increased shipments, especially to Canada, the price of pig iron is considerably firmer. The shipments last week were 7810 tons, against only 3326 in the corresponding period last year. So far as the year has gone, the increase in shipments amounts to 11,479 tons.

SCOTCH BILLS IN PARLIAMENT.—Among the Bills now before Parliament, specially relating to Scotch affairs, is the Burgh Police and Health Bill (Scotland). This Bill is under consideration by a Committee of the House of Commons, and the measure is being discussed clause by clause. An important question, upon which there has been a considerable amount of discussion, relates to the powers of the Dean of Guild Court. In Scotland this Court, whose officers are elected by the Merchants' House or Merchants' Guild of former days, is understood to grant permission to erect buildings on the submission of plans. A clause dealing with the powers of this body has been altered so as to extend the powers of the Court, so as to provide for the surveying of buildings and their certification before occupation. This places in the hands of the Dean of Guild Court a weapon which may be used effectively for the prevention of occupation of insanitary houses. Some such provision as this has been loudly demanded for some time by the medical officers in the large cities.—Evidence has also been taken before the House of Lords' Committee on the Stirling and Western District Railway Bill. The object is, by constructing a short railway from the Kilsyth and Bonnybridge Railway direct to Stirling, to reduce the distance by North British Railway from Queen-street, Glasgow, to 26¼ miles. The present distance is 29½ miles. A considerable amount of opposition has been met with by proprietors whose lands the proposed railway passes through, and the amenity of whose mansions the railway is alleged to interfere with.

RAILWAY ACCIDENT.—An accident, attended with some injury to limb, but fortunately without loss of life, occurred on Thursday, the 14th inst., to the eleven o'clock forenoon express train from Queen-street Station, Glasgow, to Edinburgh. The accident was caused by some pit props stowed on a waggon in a mineral train becoming loose, and projecting over the six-foot way. The projecting props came into contact with the express coming in the opposite direction, and before the train could be brought to a standstill, smashed the side panels of a number of the carriages, wounding the passengers, and destroying the door furniture, &c.

GLASGOW INTERNATIONAL EXHIBITION.—The numbers still keep up, the extremely fine weather of the past few days having encouraged large excursion parties. The average attendance is now about 33,000, and the aggregate number of visits registered by the turnstiles is about 1,500,000. It is now announced that the Executive are about to add extensively to the lighting of the grounds both by arc lamps and glow lamps. It has been arranged that Her Majesty the Queen will visit the Exhibition during the month of August. The Executive will have during the next two months quite a number of guests. The British Medical Association and the British Archæological Association are both to hold their meetings in Glasgow. Besides these purely scientific associations, the Institution of Naval Architects and the Society of Chemical Industry have their annual meetings here, and the Iron and Steel Institute, which meets in Edinburgh during the last week in August, pays a visit to Glasgow on the 24th of that month for the purpose of visiting the Exhibition.

THE COLLISION ON THE MEASURED MILE.—It has been found impracticable to lift the "Princess of Wales," which now lies in deep water. The "Balmoral Castle" has had the damage done to her bow made good.

THE COMPASS ACTION.—Sir William Thomson's action taken against Messrs. McGregor & Co., nautical instrument makers, Glasgow, for infringement of his patent, is reported as having been settled out of court, the defenders agreeing to certain modifications in their compass, so as to avoid infringement.

(From our own Correspondents.)

LIVERPOOL, 27TH JUNE, 1888.

THE MERSEY RAILWAY AND BOLD-STREET STATION.—The Manchester, Sheffield, and Lincolnshire Railway Company are now seeking Parliamentary powers to authorise them to construct short railways to form junctions with the Mersey Railway Company in Liverpool. It is contended by the Mersey Railway Company that if such powers are granted, the Manchester, Sheffield, and Lincolnshire Railway Company will be able to use the Bold-street Station without paying any tolls, and will thus have a Liverpool terminus provided for them at the entire cost of the Mersey Railway Company. As this station, with its approaches, has cost an enormous amount of money, the Mersey Railway Company have decided to oppose the

Digitized by Google

Bill now before Parliament, which is expected to come before Lord Jersey's Committee this week. The petition which was presented against the Bill in the Commons was withdrawn, to allow negotiations to be made between the two companies.

SHIPBUILDING. — Messrs. J. F. Waddington & Co., of Seacombe, Liverpool, have secured the contract for building a large stern wheel steamer about 170ft. long, having three decks, and passenger accommodation both for saloon and steerage. She will be fitted by the builders with compound engines, which will give a speed of 11 knots. This vessel will, we believe, be the first light draught stern wheel steamer from the Mersey to make an ocean voyage to her destination on her own bottom.

THE PRESERVED FRUIT INDUSTRY.—Mr. W. P. Hartley, of Liverpool, is building a village for the accommodation of his workpeople, and for this purpose has purchased an estate near his new works at Aintree, which he intends to lay out as a picturesque village of thoroughly useful dwellings, &c. Eighty-five competitive plans for this village have been received from architects all over the country, prizes of 50, 30, and 20 guineas having been offered for the three best plans.

LIVE AND DEAD MEAT IMPORTS.—There is a steady increase in the imports of dead meat, and a decrease in the imports of live stock from Canada and America; the total arrivals last week amounted to 1924 cattle and 8558 quarters of beef, being a decrease of 274 cattle, and an increase of 1350 quarters of beef over the previous week.

SHEFFIELD, 27TH JUNE, 1888.

IRON AND STEEL.—There has been a slight improvement in the demand for iron and steel. Scotch pig is securing a higher price, and English sorts are selling well at former, if not very much advanced, quotations. The South Yorkshire and North Derbyshire furnaces have a steady output, and there is every prospect of increasing trade. Operations are extensive at the forges and foundries, and the moulders in the latter shops are well employed. Work is fairly plentiful at the rolling mills. Armour plates are not yielding a great amount of work, nor are projectiles and ordnance being ordered in any quantity. The great activity in the shipbuilding trades is having a beneficial effect upon local industry. Ship plates are selling well at more satisfactory prices, and for marine machinery the demand is very encouraging. Screws, propeller bosses, and other important parts of ship gear are on better order, and a larger business is doing in chains. Material for bridges, and girders for building construction, are in better demand, and railway material is still in satisfactory request; tyres, axles, and springs are being sent out in large quantities. Bessemer rails are ordered freely, the prices being easy. For extensive contracts the quotations are very small. It is possible to buy at £3. 12s. 6d., and even £3. 10s., per ton, and coast makers are exporting rails at very low figures. Messrs. Craven are tolerably busy on railway vehicles, and are steadily improving their foreign business. In springs, Messrs. T. Turton & Sons are active. Messrs. Cammell and Co. are doing a good trade in rails. Agricultural machinery finds a rather quicker market. Wire for pit work, fencing, and other purposes is in brisk demand; and so are edge tools and better classes of cutlery.

LEEDS, 27TH JUNE, 1888.

THE HEAVY TRADES.—With the prospect of better prices and a brisker market, the condition of the manufactured iron trade is more satisfactory. The demand for bars, sheets, hoop iron, and some descriptions of plates is increasing; and the local call for both crucible and Bessemer steel is better. Railway plant of nearly all kinds keeps makers busy; and the well known engine builders of the town have orders on their books which will yield work for several weeks. Locomotives and traction engines are in course of construction for urgent use. Cranes and other apparatus for dock work, pumping machinery and boilers, are on more general order. Government orders are contributing, in some degree, to local industry. Engineers' tools and cut nails are selling well.

NEW SCHEMES.—There are rumours of several industrial developments in Leeds, chiefly with regard to steel making. At Denaby there is a project to erect an extensive factory for the manufacture of explosives, and the site, it is said, has already been secured.

NORTH STAFFORDSHIRE, 27TH JUNE, 1888.

THE IRON TRADE.—There is a stronger feeling amongst the iron masters of this district, and prices are somewhat firmer. Orders for export are more numerous, and for larger quantities than has recently been the case; but there is not much improvement in the home demand, and merchants' specifications are difficult to obtain. Some Belgian girders are being used in Hanley for constructive purposes, the contractor stating that having booked the work at a low figure, he has been obliged to buy the cheapest material. The pig iron market is firm, and stocks are being reduced. Contracts are being entered at prices somewhat less than those which prevailed at the close of last year. The number of furnaces in blast has not altered during the quarter.

THE COAL TRADE.—Those pits which produce only fuel suitable for domestic consumption are at a stand for orders, as owing to the hot weather the demand is very limited. The consumption of both forge and manufacturing fuel is fairly good and prices are firm, ranging from 6s. to 8s. at the pit, according to quality. Slack is hard to dispose of and prices low.

SOUTH WALES, 27TH JUNE, 1888.

TIN PLATES.—With the anticipation of a further fall in the price of block tin, plates have gone down to 12s. 6d. f.o.b. Swansea. The confident belief is expressed that tin will be sold as low as £60 within the next six months; at the same time, however, three months forward sales have been made at £80. A strike has taken place at the Gwendraeth Tin Plate Works, where, instead of 7s. per hundred boxes, the manager insisted on playing only 6s. to the employés of the wash house, these maintaining that the higher figure is paid at all other works. It is to be regretted that any difficulty should have arisen so soon after the resumption of operations following a long stoppage. It is rumoured that apart from those intended to be built by the owners of the Gwendraeth Works, another tin plate works will be erected at Llanelly at an early date. Mr. Richard Thomas, of London, purchased at a recent sale the Melin Griffith Iron and Tin Plate Works, with the buildings, plant, goodwill, &c.; the price paid being £12,000.

DISCOVERY OF A SILVER MINE.—Although nothing has been found in the South to rival Mr. Morgan's mine in North Wales, from which an ingot of gold weighing over 2000oz. has just been exhibited at the Ladies' Conversazione of the Royal Society, yet this district is not wholly without some of the precious metals. It is stated that at Llangadock, Carmarthenshire, a valuable silver mine has been discovered at a depth of about 20ft. from the surface.

WILLIAM HANCOCK & CO., LIMITED.—The directors of this Cardiff company recommend a dividend on the ordinary shares at the rate of 13 per cent. per annum, carrying £4,000 to reserve account and £2,363. 12s. 3d. forward.

BARROW-IN-FURNESS, 27TH JUNE, 1888.

THE "GREAT EASTERN."—It is probable that this ship will come to the Port of Barrow either for a complete demolition, or to be dismantled and re-fitted as a cattle or petroleum carrying steamer. The Naval Construction and Armaments Company have been interviewed by the representatives of the owners of the "Great Eastern," and have arranged with them to undertake the work. The only difficulty rests with the harbour authority as to whether the steamer can be safely docked in the Ramsden Dock.

LARGE SHIPBUILDING ORDERS.—The orders for two Pacific liners of 5000 tons each, placed at Barrow a fortnight ago, have now been supplemented with the order for two 2000-ton steamers for a British mercantile firm, and also with an important contract from a foreign government, probably the Spanish, for the construction and thorough equipment of three large and powerful high speed cruisers. These ships are to be built abroad, but the engines, machinery, torpedo fittings, Whitworth guns, Nordenfeldt quick-firing guns, and other necessary equipments for service, are to be supplied at Barrow.

IRON AND STEEL.—A steady tone continues to characterise the hematite iron and steel trade of this district; but although the demand is well maintained, and makers are well sold forward, considering the rate of the production of their works, prices do not advance; this fact may be accounted for by the heavy stocks which are held in the shape of hematite warrants, and in stocks on makers' works. 42s. 6d. is the quotation this week for mixed numbers of Bessemer iron net f.o.b., and 42s. for No. 3 forge and foundry qualities. There is a brisk and steady tone in the steel trade, and orders are offering plentifully, especially for steel rails and steel shipbuilding material. The former are quoted at £3. 17s. 6d. per ton for heavy sections, and £4 to £4. 5s. for light sections net.

MIDDLESBROUGH, 27TH JUNE, 1888.

PIG IRON.—The market continues to be steady. No. 3 G.M.B. is nominally 31s. 6d. per ton for prompt, and 31s. 9d. per ton for July-September delivery. There is very little business being done. Less Cleveland iron is being sent to Scotland on account of the decreased difference in price. The Teeside Iron Company are about to blow out two of their furnaces. It is difficult to see how a profit can be made at the present low prices, unless by those who are specially well placed as to their supplies of material. For warrants the demand is rather slack; sellers ask 31s. 7½d., but buyers will only give 31s. 6d. There are sellers of E.C. hematite pig iron, mixed numbers, at 42s. per ton f.o.b.

SHIPMENTS OF PIG IRON.—These have now fallen down to the average of former years. Up to the 23rd of June inclusive they amounted to 59,031 tons, as compared with 55,095 tons to a similar date of last year, and 87,975 tons to the 24th of May this year. The stock of iron in Connal's store is still on the decline, and stood at 283,641 tons on Saturday last.

MANUFACTURED IRON AND STEEL.—There is no change in the prices of manufactured iron and steel. Iron plates are at £4. 17s. 6d., angles £4. 10s. to £4. 12s. 6d., bars £4. 15s. per ton, less the usual discount, on trucks at manufacturers' works. Steel plates are being sold at £6. 2s. 6d., and rails (heavy sections) at £6. 2s. 6d. Iron founders are not very well off for work, but steel founders have as much as they can do. Engineers in general are fairly well off for orders.

SUNDERLAND, 27TH JUNE, 1888.

SHIPBUILDING.—During the last six months shipbuilders have had an increase of work as compared with last year; but the output does not show a very marked improvement, the increase in the number of vessels being only five. Thirty-one vessels, with a tonnage of 61,000 tons, have been launched this year, as compared with twenty-five of 48,367 tons in the first half of last year. It is, however, possible that the latter part of the present year will show a greater improvement now that the labour disputes are practically settled. The blacksmiths have this week accepted the offer of the employers of 1s. per week immediate advance and 6d. additional in August. The engineers' dispute has not yet, however, terminated. The present depression in Black Sea and other freights is not favourable to increased activity, and it is not surprising therefore that new orders are rare.

SHIPPING TRADE.—During the last week there was a slight increase in the coal shipments, the total quantity being 69,739 tons, as compared with 67,158 tons for the previous week, an increase of 2581 tons. 29,547 tons were shipped to foreign ports, and 40,192 tons coastwise, as compared with 28,570 tons and 38,588 tons respectively in the previous week. There were also exported 320,000 red bricks, 550 tons of patent fuel, 539 tons of coke, 97 tons of cement, 7000 dozen glass bottles, 63 tons of fire bricks, 20 tons of sanitary pipes, &c. The importation of mining timber was brisk, 196,132 pit props arriving, as against 127,102 in the previous week; besides 31,801 pieces of chocks, 54,194 sleepers, 5133 deals and battens, 148 bundles of iron nail rods, 347 bales of straw, 1000 tons of iron ore, &c.

NEWCASTLE, 27TH JUNE, 1888.

ROPE WORKS. — Business at the hemp and wire rope manufactories continues to be very active, the orders in hand from colliery owners being particularly numerous. There is also a fair amount of work in hand in connection with the rigging equipment of locally built steamers; and at some factories the execution of foreign contracts tends largely to maintain the present activity.

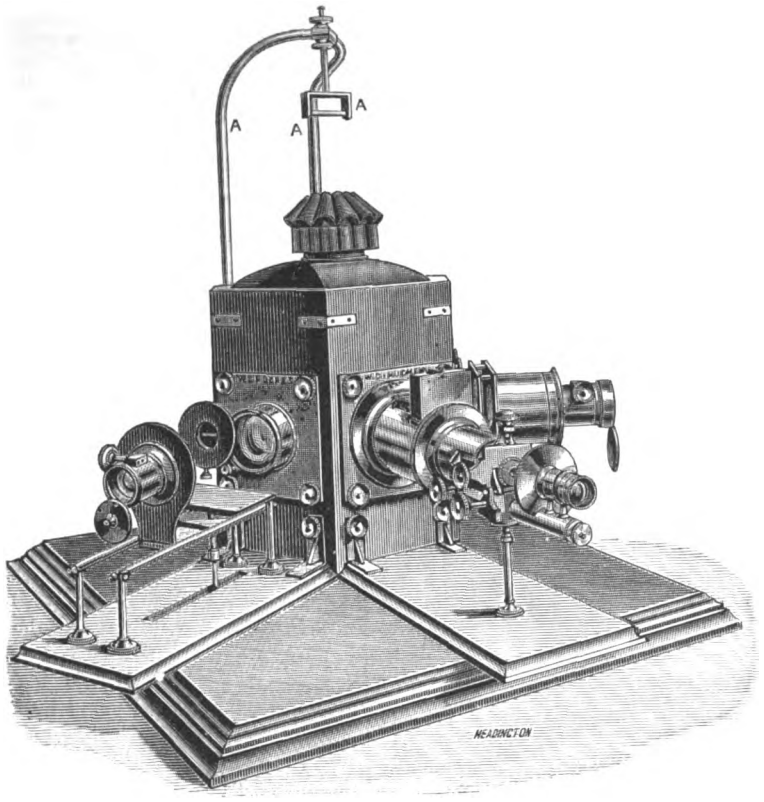
GLASS WORKS.—There is at present a large demand for the different descriptions of pressed glass ware, and the works are generally kept going to their full capacity. The bottle trade is also in a prosperous condition. The output from the Blaydon Glass Factory is large; the Gateshead Stained Glass Company have just secured several important orders to supply material for memorial windows and for general decorative purposes in churches and public buildings, and their establishment is now busier than at any former period.

CARRIAGE WORKS.—At this time of year carriage building usually receives a stimulus, and the works in this district are accordingly much busier than they were during the spring and winter months. Among other orders lately executed by Messrs. Atkinson & Phillipson were a number of broughams for the London Improved Cab Company, Limited. These vehicles were delivered to owners in May, and having been immediately put into use, are said to have given extreme satisfaction. The firm have recently forwarded a very handsomely finished phaeton to Kimberley, South Africa, and have also sent to the same destination one of their celebrated wagonette omnibuses for the use of the Bishop of Bathurst. They have besides sent a specially ordered vehicle to Bombay, and are likely to receive other contracts from the same quarter.

POTTERIES.—There is an improved demand for the different kinds of ware manufactured in the locality, with the result that the works are kept going steadily.

THE COAL TRADE.—The shipments of coal and coke at Tyne Dock, for the week ending 23rd June, amounted to 108,315 tons, being an increase, as compared with the corresponding week last year, of 31,143 tons.

BELFAST, 27TH JUNE, 1888.



SHIPBUILDING.—All the yards continue to be fully supplied with work, and orders come in as rapidly as when the trade was at its brightest. The two principal yards in Belfast have received orders for vessels of large tonnage, which will at once replace those ready for launching. The strike among riveters for higher piece work rates has been arranged after five weeks' idleness, and all the trades are now fully employed.

COAL MINING.—The Congo Coal Pits, County Tyrone, have been closed, owing to a large influx of water rendering work impossible. Much inconvenience has been caused to factories in the neighbourhood, as all their firing was drawn from this source. New pits lately opened near Stewartstown are likely to prove a great success, and will probably supply the demand until the others are re-opened. Meanwhile, a large number of workers are out of employment.

LINEN TRADE.—The market for yarns continues to be steady, and prices in the various spinnings remain as before. There is no change in prices in the range of wefts, and trade is quiet. There is a better demand, however, for the lower numbers. Stocks are considerably smaller than they have been for some time. Tows are becoming scarce, and as there is a good demand, prices are hardening. Cloths remain unchanged. The sale of brown goods continues steady, and all the looms are fully employed. Finished linens are in good demand at late prices. Shirt and collar and cuff makers continue to be fully employed. There is a decidedly better feeling all round in the trade.

HUGHES' LECTURE LANTERN.

HUGHES' LECTURE LANTERN.

At a recent meeting of the Physical Society, Mr. W. Lant Carpenter exhibited a new lantern for lecture purposes, which we illustrate above. The lantern was devised by Mr. W. C. Hughes, of Kingsland Road, London, with the special object of facilitating the change of image thrown on the screen. Thus, a lecturer can by means of this combination lantern rapidly bring before his audience first the general view of an object, next some detail, and thirdly an enlarged microscopic view of any part, simply by turning the lantern on its vertical axis; or different stages in a chemical or physical experiment can be shown in quick succession. The body of the lantern is a hexagonal prism, and each of the three adjacent front sides is fitted with projecting apparatus, the other three sides being provided with openings to give access to the interior. On the recommendation of Mr. Lant Carpenter, the Brockie-Pell focussing arc lamp has been chosen as the illuminant; but the ventilating arrangement and general construction admit also of the use of the oxy-hydrogen light, if electric energy be not available.

The first slide, that shown on the left in the illustration, is fitted with a "Gilchrist" demonstrating lantern, the prism and projecting lenses being movable along a pair of rails. The next, or middle slide, is fitted as a lantern microscope, with alum cell, mechanical stage for horizontal and vertical adjustment, and provided with various sets of lenses and objectives, whilst the third slide is arranged for spectroscopic work. To bring the beams of either one or the other of these slides on to the screen, all that the lecturer has to do is to turn the body of the lantern in the required direction, a spring catch fixing it in the exact position. To facilitate the turning, the lantern is mounted upon metal rollers.

HEAVY GUNS IN THE UNITED STATES.

According to the *Scientific American*, the South Boston Iron Works has just completed a 53-ton gun for the United States navy, which is about to be tried at Sandy Hook. It is a 12in. breech loader, and consists of a cast iron piece of 53 tons, when finished, turned, and bored, hooped and tubed with steel. The hooping consists of twenty-seven wrought steel rings, which are shrunk on and overlap so as to reinforce each other. The tube is 5in. thick, is inserted at the breech, and is 14ft. long, extending as far as the trunnions. The gun is 30ft. long. In the forthcoming trial the gun will be proved with five hundred rounds, the powder charge being 265lb., and the projectile 800lb. A Rodman gun, similarly tested, failed through erosion at the 137th round. The same firm have also in course of construction a 54-ton gun. This also is cast, and has a tube of steel 14ft. long and 5in. thick. Two "built up" steel rifled guns are also being made. They are 8in. in calibre, and to be all steel; their appearance is looked for with interest, as their success or failure will have much to do in determining the future of gun making in America. In addition, two naval carriages of the pneumatic type, for 8in. guns, are on the stocks, and four 10in. carriages of similar make for the monitor "Terror." The first 10in. rifled gun for the ironclad monitors has also been successfully tried at Annapolis. It is 27½ft. long, and weighs about 25¾ tons; its projectile is 500lb., and its charge 250lb. of cocoa powder.

THE HORSE POWER OF MARINE ENGINES.

Owing to the rapid developments which have taken place in marine engines during recent years, the ordinary methods of stating their horse power have become indefinite and unsatisfactory. Various attempts have been made to devise a method which would be generally accepted, but as yet without success. The latest has been by the Council of the North-East Coast Institution of Engineers and Shipbuilders, who have issued a report on the subject, and of which we propose to give a digest. The following is the notation adopted:—

D = diameter of low pressure cylinder in inches. If there be more than one low pressure cylinder, D^2 = sum of the squares of the diameters.
S = stroke of piston in inches.
P = working boiler pressure in lbs. per square inch above atmosphere.
H = heating surface of boilers in square feet.
P_m = mean pressure in lbs., reduced to low pressure cylinder.
R = revolutions per minute.

In order that any rule may be general in its application, all the engines to which it is applied must be assumed to conform to certain conditions, which conditions must be looked upon as normal, all other conditions being, of course, regarded as abnormal. The following six conditions are assumed: (1) That the steamer, whatever may be its boiler pressure between 50lb. and 250lb. per square inch, is expanded by the engines to the same terminal pressure. (2) That the expansion is effected by the engines with the same degree of efficiency for all pressures between 50lb. and 250lb. per square inch. From these two conditions it follows that the mean pressure reduced to the low pressure cylinder (P_m) may be assumed as proportional to the cube root of the boiler pressure ($\sqrt[3]{P}$), and further that its actual loaded trial trip value may be taken without sensible error as $5{\cdot}6\sqrt[3]{P}$. A table of calculated results shows that this assumption does not involve any material error. (3) That the piston speed of engines of different lengths of stroke are proportional to the cube root of their respective strokes; and further, that the actual loaded trial trip value of piston speed may be taken as $144\sqrt[3]{S}$. (4) That in all cases where the engines and boilers bear to each other such proportions as to prevent condition (1) from being fulfilled, without thereby violating condition (3), the coal consumption per i.h.p. will not be affected, but will be constant for the same boiler pressure. (5) That the boilers are constructed in accordance with what will be generally recognised as the fair average practice of the present day in respect of the allowance of steam room in relation to power, the diameter, area and pitch of the tubes, the relation of grate to heating surface, and the area of uptakes and funnel; that average natural chimney draught is used, or if forced draught be employed, that it does not exceed the average chimney draught; that the horse power is proportional to the heating surface (H), and to the cube root of the pressure ($\sqrt[3]{P}$); and further, that the actual loaded trial trip horse power may be taken as $\frac{H\sqrt[3]{P}}{16}$. (6) That the efficiency of the engine mechanism is constant, and that the propeller is such as to secure that the engines will utilise the boiler power referred to in condition (5) in the manner prescribed in conditions (3) and (4).

Then the proposed rule is deduced in the following manner:—

$$\text{I.H.P.} = \frac{\frac{\pi}{4}D^2 \times P_m \times 2SR}{33000}$$

substituting from conditions (1) and (2)

$$= \frac{\frac{\pi}{4}D^2 \times 5{\cdot}6\sqrt[3]{P} \times 144\sqrt[3]{S}}{33000}$$

By reduction

$$= \frac{D^2\sqrt[3]{PS}}{52} \quad \text{.....(A)}$$

$$\text{I.H.P. of boilers} = \frac{H\sqrt[3]{P}}{16} \text{ condition (5) ..... (B)}$$

If we suppose that (A) and (B) are equal, we obtain

$$H = \frac{D^2\sqrt[3]{S}}{3{\cdot}25} \quad \text{.....(C)}$$

This expression gives the normal relation between the engines and boilers.

Assuming that the power of the engines and boilers when taken together will be equal to the mean of their separate powers, we have:—

I.H.P. of combined engines and boilers

$$= \frac{\frac{D^2\sqrt[3]{PS}}{52} + \frac{H\sqrt[3]{P}}{16}}{2}$$

$$= \frac{(D^2\sqrt[3]{S} + 3{\cdot}25H)\sqrt[3]{P}}{104}$$

which, without sensible error and for convenience, may be written

$$= \frac{(D^2\sqrt[3]{S} + 3H)\sqrt[3]{P}}{100}$$

and it is proposed to call the result the normal indicated horse power (n.i.h.p.).

For paddle engines the same rule may be used, with its co-efficients modified to meet the altered condition of piston speed which usually obtains in these engines. Assuming that under condition (4) the piston speed of paddle engines may be taken at $90\sqrt[3]{S}$, the rule may, without sensible error, be written

$$\text{N.I.H.P. of paddle engines} = \frac{(D^2\sqrt[3]{S} + 5H)\sqrt[3]{P}}{160},$$

and equation (C) would become $H = \frac{D^2\sqrt[3]{S}}{5{\cdot}2}$.

The Council considers the term "nominal horse power" very indefinite and misleading as a measure of the power of marine machinery. If, however, instead of *indicated* power, a quantity be required which will compare more nearly with what is known as "nominal horse power," the above rule may be used thus:—

$$\text{Nominal horse power} = \frac{\text{N.I.H.P.}}{6}.$$

We understand that the Council of the North-East Coast Institution has sent the report to the various engineering Institutions for discussion, so that something like unanimity may be arrived at. We are therefore likely to hear a good deal on the subject at the beginning of the next sessions of these Institutions. In the meantime, however, we should be glad to have the opinions of some of our readers regarding it.

Advertisements intended for insertion in the current week's issue must reach the Manchester Offices not later than first mail delivery on Thursday morning. Scale of charges for displayed advertisements on cover and inside pages will be forwarded on application. Orders for single advertisements must be accompanied by payment in order to insure insertion, the charge for which is 2s. 6d. for the first four lines or under, and 6d. for each additional line; one inch and over at 7s. per inch; the line averages eight words. While all practical regularity in the insertion of serial advertisements will be observed, it can only be absolutely guaranteed in the case of those ordered to appear weekly.

All accounts are payable to the Publisher, GEO. CAWLEY, *70, Market-Street, Manchester. Cheques should be crossed Manchester and Liverpool District Bank, King-street Branch, Manchester. Post Office Orders to be made payable at Manchester.*

FRIDAY, 29TH JUNE, 1888.

THE NEW ELECTRIC LIGHTING ACT.

THE Bill amending Mr. Chamberlain's Electric Lighting Act of 1882 has now passed both Houses of Parliament, and only awaits the Royal assent to become law. Considering the great outcry which was raised by electric light engineers and contractors shortly after the passing of the original Bill, the present Bill—which was drafted with the distinct purpose of removing certain obstacles which hitherto were considered to hinder the development of the electric lighting industry—has attracted very little attention outside the circle of its parliamentary promoters and supporters. It is a short Bill of five clauses, and in general character does not materially differ from the Act of 1882, with which it will be incorporated. In one respect, however, it is a decided improvement over that Act. The great objection of electric light contractors to Mr. Chamberlain's Act was, that any successful electric light station was under it liable to be compulsorily purchased by the local authority after the lapse of twenty-one years, the price to be paid covering only the market value of the plant at the time of purchase. Where improvement is so rapid as in electric light machinery, the market value of the plant a few years after its erection is liable to be considerably below its first cost, and therefore the recompense represented by the purchase money would not have been equivalent to the outlay even after a few years. A glance at the price lists published by the leading dynamo makers five years ago and those published now will make this evident. The price of low tension dynamos, suitable for central station work, shortly after the passing of the Act averaged over £1 per lamp; now it is barely half that amount. It is evident that had a company started some five years ago, they would have had to purchase their machines at the high figure of £1 per lamp, and would have had to sell them, under the compulsory purchase clause, at the lapse of twenty-one years, to the local authority at less than 10s. a lamp. This would have represented a dead loss of one half their original outlay, to say nothing of the expenses of repairs and the effect of depreciation, which represent a further sacrifice. As it is with dynamos, so it is with all the other plant in the station, and capitalists were consequently hesitating to embark in a business which was practically untried as far as its earning powers were concerned, whilst the prospective and inevitable losses, resulting from the purchase clauses, were considerable. It has been the fashion with electric light engineers to lay all the blame for the want of progress in central station lighting in this country on the original Electric Lighting Act, but in this we think they were wrong. No doubt the Act has tended to retard progress, but there were other forces at work tending to the same result. The cheapness of gas, the conservatism of the public, the mistrust in which electric light investments were held by capitalists, owing to the over-speculation of 1881 and 1882, and last, but not least, the technical obstacles which formerly stood in the way of long distance distribution, were at least as really effective in checking the development of central station lighting as Mr. Chamberlain's much abused Act. With Lord Thurlow's Bill the obstacle of compulsory purchase, although not completely removed, has been greatly reduced. Under the new Act the local authority can only effect a compulsory purchase after a term of forty-two years, and this seems to be a sufficiently long time to enable the owners of a central station to reap all the benefits of further improvements in plant before they incur the loss of having to sell their plant at its bare market value. Clause 2 of Lord Thurlow's Bill is almost identical with the famous Clause 27 of Mr. Chamberlain's Act, except that the period after which compulsory purchase can be made is forty-two, and not twenty-one years, and that the subsequent periods for compulsory purchase have been increased from seven to ten years. Thus, if after the lapse of forty-two years the local authority do not elect to acquire the electric light undertaking, the original owners will have a further tenure of ten years at least. But in the present as in the previous clause the objectionable words that the purchase is to be made "without any addition in respect of compulsory purchase or of goodwill or of any profits which may or might have been or be made from the undertaking, or of any similar considerations," are left standing. Electric light companies must, therefore, not rely on payment for goodwill, and the main advantage the new Bill will confer upon them is that they will be left in undisturbed positions for a time long enough to enable them, if the business be fairly successful, to pay off the original capital before the evil day arrives when they will have to deal with the local authority.

Simultaneously with Lord Thurlow's Bill there was introduced another Electric Lighting Act Amendment Bill by the Earl of Crawford. This was allowed to drop, although in our opinion it was by far the better Bill of the two. In it there was no time fixed for compulsory purchase, but such purchase could take place if either through the insolvency of the undertaker or the unprofitable nature of the undertaking, or by mutual agreement between the undertakers and the Board of Trade, the latter should revoke the agreement under which the undertakers carried on the works. The price to be paid to the undertakers in such compulsory purchases was to be settled by the average market value of the shares or stock of the concern during the five years immediately preceding the sale. As the Bill expressly stated that no monopoly should be granted to any electric light undertaking, and as the conditions of supply and the maximum price to be charged were specified in the Bill, the security of tenure which the purchase clause conferred to the electric light undertakers could in nowise be disadvantageous to the consumers, and we would have much preferred to see the second clause of Lord Thurlow's Bill replaced by some such provision as was unfortunately lost with the Earl of Crawford's Bill.

We have, however, to deal with the Bill which has now passed, and must point out some other alterations embodied in it. One of these refers to the consent of the local authority. According to the Act of 1882 a license for seven years would only be granted by the Board of Trade with the consent of the local authority, but for a provisional order no such consent was required. According to the new Bill, "no provisional order authorising the supply of electricity by any undertakers within the district of any local authority shall be granted by the Board of Trade except with the consent of such local authority, unless the Board of Trade, in any case in which the

Digitized by Google

consent of such local authority is refused, are of opinion that having regard to all the circumstances of the case such consent ought to be dispensed with, and in such case they shall make a special report stating the grounds upon which they have dispensed with such consent." The principle of free competition has found expression in an amendment introduced in the House of Commons, according to which "the grant of authority to any undertakers to supply electricity within any area, whether granted by license or by means of a Provisional Order, shall not in any way hinder or restrict the granting of a license or Provisional Order to the local authority, or to any other company or person within the same area." The Board of Trade is also given power to vary the terms upon which the local authority may require the undertakers to sell, if such terms have previously been agreed upon between the local board and the undertakers. The clause giving the Board of Trade power to control electric light lines or other work in public streets has been slightly enlarged, and the penalty to which undertakers are liable for interfering with the wires of the Postmaster-General has been increased from £10 to £20 for each day during which the contravention or wilful non-compliance with the orders of the Board for the protection of telegraph lines continues. We have given in the foregoing a brief sketch of the new Bill, which is in future to be cited and construed together with the original Act of 1882, under the title of the Electric Light Acts, 1882 and 1888.

On the whole electricians, and especially electric light contractors, will have reason to be satisfied with the new Act. If it does not give them all they asked for, it has certainly removed the greatest legal obstacle which has hitherto stood in the way of a public supply of electricity. It remains now to the profession to show that they are able to overcome the technical and financial obstacles to which we have alluded.

TEXTILE STATISTICS.

II.

The worsted industry, and the production of machines connected with it, are principally carried on in the Bradford district, which comprises Bradford as well as the towns of Shipley, Saltaire, Bingley, Keighley, Haworth, the Airedale up to Skipton, Burley, Otley, Thornton, Queensbury, Shelf, and part of Halifax. The value of the capital invested in the wool industry of the Bradford district was in 1884 estimated at 60·4 millions sterling. The Bradford district is still the principal producer of men's wear goods, and also for the lower qualities of women's wear goods; whereas the better qualities are imported from foreign countries, principally from France. Of the total productions of the Bradford district in 1884, there were exported 10 per cent. to the Colonies, and 35·4 per cent. to other countries, so that 56·6 per cent. remained in the country. In the Bradford district alone three-fourths of all the English and all the Irish wools are manipulated in so far as the raw material is combed and spun there; Huddersfield, Leeds, Leicester, and the West of England district being supplied with yarns from Bradford. It is remarkable that whilst the consumption of English wools is on the decline, that of merino wools, South American, Australian, and South African wool is increasing considerably. Particularly favourable periods for the Bradford district were the times of the American Civil War, and the years during and after the Franco-German War. Business was fairly remunerative up to the year 1874-75. Then over-production set in, followed by very heavy losses in some branches of the industry. Losses of this description were not experienced to the same extent in other countries. According to the official statement of the Board of Inland Revenue, the Bradford district shows the following fluctuations in the returns of commerce and industry during the last twenty-five years:—

	£
1860-64	1,414,049
1865-69	2,028,602
1870-74	2,943,783
1875-79	3,001,446
1880-84	2,405,346
1885	2,502,663

The losses referred to principally affected the so-called "staple" industries of Bradford, which even to-day are carried on with but scanty profits. These staple industries, that is to say, the production of worsted stuff goods, may be divided into three parts, viz., the manufacturing of those stuffs which are made of long lustrous wools mixed with cotton (*i.e.*, cotton warps); of those stuffs which are made of merino wools mixed with cotton; and of those stuffs which are made of all-wool. The Bradford district produced principally the stuffs of the first two descriptions. According to the report of the Royal Commission, the principal reasons of the considerable decline which these staple industries experienced in the years 1875-80 were: The protective duties of other countries; the change of fashion to all-wool goods, the so-called "merino dress fabrics," in which especially France has been excelling for years back; the competition of foreign countries; and the diminished demand of the Continental States. Whilst the staple industries of the Bradford district have experienced such a decided decline, some branches of industry (the so-called "new industries") have been greatly developed in that district. These industries, which have rapidly attained such importance, are principally the worsted coating industry, plush industry, the silk warp cashmere industry, and the machine industry.

The worsted coatings favoured by the change of fashion to combed yarn stuffs, took the place of the West of England cloth and of the Scotch cloth. Whilst the dress goods are made of cotton warp and worsted weft, these worsted coatings contain mostly worsted yarn, and differ materially from the former. They are at present chiefly manufactured in Bradford, Halifax, and Huddersfield, while in Leeds, Batley, and Dewsbury coatings are made of cotton warps with shoddy weft. Another branch of industry which has been thriving in Bradford for the last ten years is the spinning of silk waste, and the yarn thus obtained is used for sewing silk, children's dress goods, and plushes. The silk warp cashmeres are exported principally to the United States of America. Besides the above mentioned new industries of the Bradford district, the spinning and yarn trades have experienced a considerable development, caused by export as well as by home consumption of its products.

Referring now to the tweed trade, which derives its name from the manufacturing district traversed by the river Tweed, some of the principal towns in that district being Galashiels, Selkirk, Peebles, Innerleithen, Hawick, Langholm, Jedburgh, and Dumfries. The tweed manufacturers still find their principal market in London and Glasgow. During the last few years the direct export to Germany and France has increased, German and French buyers visiting the manufacturing districts twice a year. The export of the tweed trade to Germany is fairly considerable; next in importance come France and the United States of America. Italy imports only small quantities, and the export business to Russia is said to be annihilated by the imposition of protective duties. The Scotch wool industry has to compete with the English, as well as foreign markets, also with the affiliated industries of other British industrial districts, and lately German and French manufacturers are also entering into competition, after having learned to comply with English tastes. This is especially the case in dark coatings. In the Colonies, especially in Australia, the German competition in wool fabrics, chiefly in dark coatings and thin summer goods, has been very keen. The present position of the tweed trade is described as being depressed. The decrease of business began in the year 1877, a little improvement manifesting itself in 1880. Soon, however, a relapse set in, which has prevailed during the last five years. In 1885, 25 per cent. of the looms were idle. It was especially the change of fashion to worsted coating goods which during the last eight years proved fatal to the South Scotch industry, because the manufacturers would not entertain the idea of changing their machinery. At present principally worsted yarns are used which are bought in Yorkshire. Latterly the exports in Cheviots, especially to America, has risen considerably.

In no branch is the utilisation of apparently worthless material carried on with so much success as in the artificial wool industry. The most important product, the "shoddy," is produced from the "softs," viz., from worn out stockings, flannels, woollen fabrics, &c.; the "mungo" is produced from the "hards," *i.e.*, tailors' cuttings, worn out clothes, rags, &c. "Extract" is the name of the fabric which is produced by a mixture of cotton or linen with the wool extracted from rags. The waste from these processes, called "flocks," often seems to be little better than sweepings, but even this is turned to use. The shoddy industry originated in the year 1813 in Batley and Dewsbury, in Yorkshire, and the principal development took place in the period 1840-60. An important branch of this industry consists of the union cloth manufacture, so called on account of the cotton warp and woollen weft, and the cloth made by this process has the appearance of an all-wool fabric. Shoddy goods were for many years looked upon as base imitations; but are now considered a benefaction to mankind, because they bring warm clothing within the reach of the millions. The total weight of shoddy, mungo, &c., annually produced in England is estimated at 125,000,000lb. There are at present 108 shoddy factories in the United Kingdom, England and Wales having 107, and Scotland 1. This industry employs 93,766 spindles and 2222 doubling spindles, 1921 power looms, and 4709 hands.

The hosiery trade branch of the English textile industry has not suffered very much from the general depression. Lately, however, complaints have been heard that the profits are inadequate in proportion to the capital invested and the labour bestowed upon it. A few years ago English manufacturers thought that the competition of Saxony, especially Chemnitz, would have a material influence upon the hosiery trade. However, it seems at present that the Saxon competition is only confined to two or three articles. In 1885 the export of cotton hosiery goods amounted to £741,822, while the export of woollen goods only amounted to £555,448. The export of woollen hosiery to Germany amounted to £28,827, and cotton to £4,311. There are at present 227 hosiery factories in the United Kingdom. Of these 215 are in England and Wales, and 12 in Scotland. There are altogether 19,536 hands employed in this industry, as against 14,992 hands in 1878, which is an increase of 307.

NAVAL ORGANISATION.

The subject of our national defence continues to be vigorously discussed at various meetings and in the general Press, and the variety of opinions expressed must require cool judgment on the part of the members of the Government, who are directly responsible for the organisation of the necessary measures, to enable them to decide which of the numerous suggestions offered to them should be adopted. One of the most energetic of those who are endeavouring to rouse public opinion, and stimulate official action in the matter, is Lord Charles Beresford, and his position in Parliament, and an ex-Lord of the Admiralty, naturally cause considerable attention to be paid to his utterances. There is an impression, however, even among his warmest admirers, that his sayings and writings are very similar in their nature to his actions on board ship or in the field, that is, that there is more reckless bravery about them than cool, calculating common sense, such as is required in the guidance of any large government department. Some of his recent utterances are, however, worthy of attention, because if they are not useful for drawing out a constructive policy, they at least indicate the weak points in the present arrangements, as he has no hesitation in using the knowledge he gained in his official position to show the weakness of our present arrangements. We will, therefore, briefly notice a few of his criticisms and proposals. He insists very strongly on the difficulty or impossibility of fixing responsibility on those who are to blame for any defect in the arrangements or management, or for any insufficiency in the number of ships, or the amount of their armaments. On this latter subject, he says that if we were called upon to enter into hostilities with two great maritime Powers — as, for instance, France and Russia—that those who would work and take the command of the British fleets and squadrons are unanimous in their opinion that the fleet would not be sufficient in number or strength for such an eventuality. He says that the controversy between the experts and the party politicians or officials has arrived at a stage of simple contradiction, the Parliamentary officials maintaining that the tonnage and number of ships is in favour of Britain, while the others (the experts) maintain that such comparisons are useless, futile, and misleading, and that the only comparison worth viewing with interest is that which compares the work thrown on the respective fleets—viz., Britain against any two combined Powers—in case of war. This argument can only be determined by naming the fleets and ships, together with the localities where they must be employed, and the work they would have to do, and by pointing out those contingencies which are certain to occur in time of war. He indicates that probably a line of this character will be taken in the House of Commons on the shipbuilding vote, when the public will be able to see the facts of the case as they exist. We will therefore postpone the consideration of this part of the subject for the present; but it must be remembered that party politicians and those officials nominally responsible for the navy have, time after time, assured the country that the naval defence was complete, the finances administered in the most economical manner, and the navy itself thoroughly organised and ready for any emergency, but that, when occasion has arisen to substantiate these statements, they have without exception been falsified. He, however, is not inclined to blame the officials too heavily for the subsequent discovery of their inaccuracy; but he expresses the opinion that the system that allows such misconceptions must be ridiculously bad, and, in fact, rotten.

Lord Charles points out that with the present system it is quite impossible to fix the responsibility for anything that may go wrong upon any individual, or upon what is

Digitized by Google

called the Board of Admiralty as a whole, and he justly remarks that unless responsibility can be clearly defined and firmly fixed, it is impossible that any system of administration can be sound or wisely and well conducted. He complains that while the seamen are held responsible for their own departments, and to the First Lord for their efficiency, it is within the power of the First Lord to ignore the advice or proposals which a Naval Lord may urge as being necessary to make his department as efficient as possible; but in the event of the First Lord not heeding this advice, he asks, who then can be said to be responsible. He further complains that the so-called Board of Admiralty is not worked as a Board, that the distribution of business is not suitable for modern requirements, some of the Lords having too much to do, others too little; that there is an immense gap between the executive of the Admiralty and the officers and men of the fleet; and, lastly, that the appointment of the seamen on the Board is not satisfactory, and is not regarded with confidence in the service. His Lordship, however, is not content with mere criticism, for in his latest utterance he puts forward a scheme for what he calls "A Workable Admiralty," which, however, he says is largely due to Mr. McHardy, an official at the Admiralty. He contends that the first essential is to abolish the fiction of a Board, and in its place to give the First Lord of the Admiralty three chief officers, each of whom would be individually and actually responsible to him and to the nation for his respective department. The First Lord should be able to call on these officers, or upon any others serving under them as heads of departments, to meet in consultation and settle matters in which their duties might be concerned, and by this means every matter connected with the fleet which required reform could be ventilated, but individual responsibility would be directly and entirely maintained, and the irresponsibility of the present system of governing by the fiction of a Board would disappear. Instead of the officials being called a Board, they might be denominated the Controller-General for the Personnel, the Controller-General for the Matériel, and the Parliamentary Secretary for the Finance. The Admiralty would, according to this scheme, be divided into three departments, each under a responsible head, who (with the exception of the Parliamentary Secretary) would not change with the Ministry, but should be appointed for a period of three or five years. Each of them should have a deputy, who would be a permanent official, and would be empowered to deal with certain questions, to act for his chief during his absence, and in the intervals of change of office to keep up the continuity of the business. Each of these three great departments would be further sub-divided into sections under a responsible head, who should make to his chief an annual report in regard to the state of the duties under his charge—the work done during the past and that proposed for the ensuing twelve months, accompanied by a financial report, showing the expenditure of the past year compared with the amount voted, and the estimated amount required for the ensuing twelve months. These reports and estimates from the several officers of the three great departments should be collected by the head of the department, and be forwarded with his remarks to the First Lord, who should then write his decision thereon as to the money that Parliament is to be asked to vote for the navy for the ensuing year; these reports, with the decision thereon, being laid before Parliament with the navy estimates.

A detailed scheme is given of the distribution of the duties and staff at the Admiralty if it were organised in the manner indicated. We cannot enter into details of that scheme, which seems to be very complete so long as the navy is not required for fighting purposes; but no provision seems to be made for a general staff, whose duties would be quite distinct for the administration of the navy, and the decision of the tactics or policy to be adopted in case of hostilities. The only addition proposed to the existing staff in the matériel department is that of a Director of Dockyard Accounts, the other chief officials being the Director of Naval Ordnance, the Director of Naval Construction, the Director of Engineering, the Director of Dockyards, and the Director of Stores. Each of these departments, however, seem to require strengthening on the professional side, as a great deal is done at present in a haphazard manner. Arrangements ought to be made for the First Lord having available the assistance of the highest authorities on any questions which may arise, not necessarily by multiplying the number of permanent officials to an unlimited degree, but rather by calling in competent advice on special occasions. If in addition a general staff were organised which would be responsible for the operations of war, in case that broke out, and in time of peace made arrangements and collected information which could at once be utilised in case of hostilities, then we might have a really "workable Admiralty," and not simply one which, while fully developed as a manufacturing and administrative concern, has overlooked the chief object of its existence, viz., its ability and readiness to fight.

CARBO-DYNAMITE.

Messrs. W. Borland & W. Reid have lately patented an explosive, in which the active agent, nitro-glycerine, is absorbed by carbon instead of kieselguhr. As carbon is an inflammable substance, complete combustion is claimed, and thus the noxious evolution of carbonic oxide from unconsumed particles is avoided, which often is due to the non-inflammability of the kieselguhr. The objections to ordinary dynamite are the fumes almost invariably met with in shafts and tunnels, the occurrence of "dynamite headache" from the mere handling of the charge, and the dangerous exudation of nitro-glycerine from the absorbent should the charge get wet. In addition, if a damaged cartridge is put into a bore hole, some of the nitro-glycerine may adhere to the sides, and the subsequent tamping of the hole may lead to fatal results. Many attempts have been made to use an absorbent which will minimise these dangers; but, in the majority of cases, the expense has thereby been greatly increased. For the present invention three important qualities are claimed, viz., a price not higher than ordinary dynamite, a greater explosive force, and the fact that water has no effect upon the material. The greater explosive force is said to be due to the fact that 90 per cent. of the charge is composed of nitro-glycerine, whilst the absorbent itself is highly combustible; whereas, the amount absorbed by kieselguhr is much lower, and the absorbent represents so much inert substance. A series of tests has lately been carried out at Treherbert, South Wales, which went far to substantiate these claims. The carbo-dynamite, in competition with No. 3 dynamite, appeared to have greater power when tried by blasting boulders in a bore hole in the heading of a tunnel under construction, and in similar lead cylinders. The absence of the usual fumes, when both were exploded in turn in an ordinary shaft, was only noticed in the case of the new compound, which also was the most successful in denting a steel disc and rending a steel tube. To show the relative solubilities of the explosives, equal quantities were placed in clear bottles, which were filled with water. After some time, the water in the bottles containing dynamite assumed the consistency of pea soup, while that in the other bottle remained unchanged, even when the bottle was violently shaken. It is stated that some carbo-dynamite placed in water eight months ago presents the same appearance now as when first immersed, and that its explosive quality is unaltered. It is also claimed for carbo-dynamite that it can be prepared with a large percentage of water, the steam from which, on explosion, at once extinguishes all flame, so that the explosive is eligible for use in coal mines and other dangerous places.

Letters to the Editor.

THE LEAMINGTON CENTRAL ELECTRIC LIGHT STATION.

To the Editor of "Industries."

Sir,—I shall be glad to correct two errors of detail in your otherwise accurate account of our Leamington installation. You speak of the device by which we keep a constant potential at the distributing centres as "a compound Shuckert voltmeter." The voltmeters are ordinary Shuckert voltmeters, and, so far as I am aware, the plan of compounding for this purpose does not in any way belong to Shuckert. The particular method of adjustment which you describe, and which we have found of great practical utility, is due to our electrician, Mr. R. H. Housman. A second rather important error occurs in your description of my current meter. You say, "in most cases only a small portion of the main current is passed through the meter." Now, although, as I explained at the time, we find the meters perfectly accurate when this is done, as a matter of fact our usual practice is to pass the whole current through the meter. Thus, at Leamington, the only exceptions to this rule are at the central station and at the Town Hall (360 lights), the reason being that the largest meters we have as yet made are for about 60 ampères; but we have now in hand a type that will carry 500, which we shall use at the central station.

Yours, &c.,
George Hookham.

Birmingham, 25th June, 1888.

REFLECTORS FOR DISTRIBUTING LIGHT.

To the Editor of "Industries."

Sir,—I am interested to learn from your account of the Leamington electric light station, that reflectors are being used for the purpose of uniformly distributing the light of glow lamps, although in this case, in my opinion, the illumination would be practically uniform without any such device. With lamps, or groups of lamps, placed at a distance apart equal to their height above the ground, the maximum illumination is 1 + the sum of cos ^{3} of the angles whose tangents are 1, 2, 3, 4, &c.=1·976. The minimum illumination is equal to 2 cos ^{3} of the angles whose tangents are 0·5, 1·5, 2·5, 3·5, &c.=1·91. The greatest variation is, therefore, about 3½ per cent. In a room 80ft. by 40ft. by 28ft. high, with five clusters of lights, the variation would be inappreciable to the most skilled photometrist, especially when the distribution would be assisted by the reflection from the walls. For street lighting, however, such reflectors should be of material service. The London gas lamps are generally 12ft. high and 66ft. apart, the distance being five and a half times the height. The variation under these circumstances is very considerable; the illumination at a point on the ground midway between the lamps is about one-thirteenth of the illumination which would be found below the lamp, if it cast no shadow. A few years ago—perhaps a few years too soon—I made a study of this subject, and with your permission I will send you some notes on the distribution of illumination, and the geometrical design of reflectors for street lighting, &c.

Yours, &c.,
2, Victoria Mansions, Westminster, 26th June, 1888. Alex. P. Trotter.

Books Received.

Mechanics' Workshop Handy Book. By Paul N. Hasluck, A.Inst.M.E. London: Crosby Lockwood & Co.

Manual of Steam Boilers; their Design, Construction, and Operation. By R. H. Thurston, M.A. New York: John Wiley & Sons. 1888.

A Short Text Book of Political Economy, with Problems for Solution. By J. E. Symes, M.A. London: Rivingtons. 1888.

The Phœnix Fire Office Rules for Electric Light Installations. Thirteenth edition. London: Phœnix Fire Office.

Calvert's Practical Notes on Screw Cutting. By Wm. Ward. Manchester: John Calvert.

The National Boiler Insurance Company, Limited: Chief Engineer's Report, 1887.

Geschichte der Transformatoren. Von F. Uppenborn. Munich and Leipsic: R. Oldenbourg.

Reviews.

A Manual of Steam Boilers: their Design, Construction, and Operation. By R. H. Thurston, M.A., Doc. Eng., Director of Sibley College, Cornell University, &c. New York: John Wiley & Sons. 1888.

We have had occasion to review recently several books which in our opinion are a good combination of theory and practice, and well suited to the wants of many of the rising generation of engineers. The mere pocket book crammed with empirical formulæ, or the results of experience in different classes of engines, or the treatise which solved problems conceived under all sorts of imaginary conditions, suited the merely practical man or the physicist; but the modern engineer who has combined with a fairly good training in theory a lengthened experience in the workshops, is not likely to be content with either the one or the other. He wants a book which will keep fresh in his memory the fundamental principles he has studied, and at the same time show how these are applied to the problems of everyday life. Professor Thurston's treatise has been designed for technical schools and engineers, and we believe that it will be found useful in both these capacities. It is chiefly nonsense to state, as a contemporary recently stated, that "the notion that a school text book is likely to prove useful to engineers making or designing boilers seems to us to be a complete mistake, for the methods of the schools are not the methods of the counting house or the drawing office. The boiler engineer does not necessarily know anything of thermodynamics; the practical construction of steam boilers and their management being either determined by hard and fast conditions perfectly understood, or modified by circumstances with which thermodynamics have about as much to do as Sanscrit. We do not say that thermodynamics should not be taught; on the contrary, we think that the whole science of heat should be taught with the utmost care, but not in connection with the construction of steam boilers." We would like to know, if thermodynamics is not to be taught to engineers who make steam engines and boilers, to whom should it be taught? If our contemporary be correct, the numerous chairs of engineering which are being founded, and the technical institutions which are being erected, are all useless, and the money expended would be more usefully employed in publishing cheap editions of all pocket books which have ever appeared. To say that the methods of the schools are not the methods of the counting house or the drawing office, is only to admit that hitherto neither schools, counting houses, nor drawing offices have been conducted as they ought to have been. We know several large engineering and manufacturing concerns which carry on immense businesses in which, if a stranger were suddenly placed, he would in some of the departments imagine he was in a technical school—everything he saw being in the way of investigation, measurement, calculation, or analysis. On the other hand, many of the best technical schools now carry on work which is of

Digitized by Google

direct practical utility to the engineer, and the more their methods are perfected, the approximation of certain departments of the technical school, the drawing office, and the counting house will become closer. Sibley College, which is connected with Cornell University, and of which Professor Thurston is the director, and for the students of which the book we are considering has been chiefly written, with its laboratories, drawing offices, and workshops, is one of the best examples of the modern schools for engineers, and the students who leave it and similar institutions are not likely to be satisfied with simple empiricism.

Professor Thurston explains that his treatise is the outcome of an attempt to meet a demand which has been repeatedly made for a fairly complete, systematic, and scientific, yet "practical" manual, and it is intended to be sufficiently comprehensive to meet the wants of the engineer in his office, and yet so rigidly systematic as to be suitable for use as a text book in schools of engineering. It has been the endeavour of the author to incorporate the elements of the subject just so far as they are needed in preparing the way for the work of the designer, the builder, and the manager of steam boilers, while also amply complete and logical to permit the use of the book in the instruction of the student in applied science. He, however, explains that it was not to be expected that it would be found practicable to make a manual of this kind absolutely complete as a workshop treatise to be used by the boiler maker; but he hopes that within these limits it will be found fairly satisfactory to the engineer engaged in designing.

The plan of the work as explained by the author is as follows: Beginning with a historical and descriptive introduction, in which are traced the various developments of the apparatus used by the engineers of the time of Watt and earlier, and by his successors, and the progress made since his time to date, the existing standard forms of boilers are described and classified, and their special adaptations indicated. A chapter is devoted to the study of the characteristics of the materials used by the engineer in the construction of steam generators, and another to the strength of these metals in their several forms and compositions, the methods of adaptation to the purposes of construction, and to the statement of the precautions in their introduction into so important a structure. These two chapters form a very convenient *resumé* of the subject of the strength of materials as applied to steam boilers, and are largely adapted from the author's larger work, "Materials of Construction." Another chapter is appropriated to the examination of the composition and relative values of the various available fuels, and their economical use in the production of steam. Then follow chapters on heat and thermodynamics, which are as complete as the space will allow. Whether the statement which is given of the Second Law of Thermodynamics is the one which is most likely to convey the best idea of its meaning and consequences is, however, doubtful. The chapter on steam, vaporisation, superheating, condensation, pressure, and temperature is a useful synopsis of the physical properties of steam. Then follow chapters which are more directly connected with the designing of steam boilers. That on the conditions controlling boiler design is a clear statement of the different factors in the problem, while the next two explain the principles of boiler design, the accessories of boilers, and the design of chimneys, and should prove sufficient for their purpose, being fairly concise and very definite. The chapter on the construction of boilers, of course, is not a complete treatise on the subject, but still it gives a very good outline of the various processes; while the one which follows gives examples of the specifications of the chief types. The chapter on the operation and care of boilers and their management generally is founded chiefly on the experience of the author, and contains much useful information, and will be found interesting, especially to the class of young men to whom it is addressed.

In the chapter on trials of steam boilers, the methods reported favourably to the American Society of Mechanical Engineers are adopted as a standard, and the report of the committee is taken almost bodily into the text. As, however, the report was prepared by the author, this liberty is quite justifiable. The last chapter on boiler explosions is a reprint of a monograph by the author on the subject, and gives a *resumé* of the different theories of the causes of explosions, and a considerable amount of miscellaneous useful information bearing on the subject. One of the conclusions at which he arrives is that all explosions are due to simple and preventable causes, and nearly all to simple ignorance or carelessness on the part of either designer, constructor, proprietor, or attendants. That being so, the proper method to adopt for the prevention of explosions is to throw the responsibility for their results on the owners of the boilers, who would then be pretty certain to take very effective means to prevent them. Altogether the book is a most valuable one, and we have much pleasure in commending it to the attention of our readers.

ELECTRICITY AND MAGNETISM. By E. Mascart and J. Joubert. Vols. I., II. Translated by E. Atkinson, Ph.D. London: DE LA RUE & Co.

It is only a little more than half a century since Oersted made his celebrated discovery, and Ampère, the "Newton of electricity," gave his remarkable memoirs on electro-dynamics to the world. In the interval electrical science, as we now know it, has grown up. Faraday's researches, and the investigations of Green, Weber, Thomson, Helmholtz, Maxwell, Kirchhoff, and many others, have paved the way for the practical applications of electricity, which now concern the engineer quite as much as the pure scientist. The volumes before us may be said to contain a systematic and fairly complete outline of the work which has been done during the period we have mentioned. By the arrangement adopted, the treatise is divided into two parts. Vol. I. deals with general phenomena and theory, and Vol. II. contains methods of measurements and practical applications. This arrangement has its advantages and also its objections. For a student, no doubt, from one point of view, it is advantageous to have put before him, in the first place, a connected account of the main experimental parts, and the theory by which they are connected, and then to proceed to build a more practical and quantitative knowledge on this as a foundation. But, on the other hand, it often sheds light on a theoretical investigation to find its application ready at hand, to find, for example, a closer connection than is here the case of theoretical investigations of the properties of dielectrics, with measurements of specific inductive capacities, and of theory of flow of electricity, with the practical problems which present themselves in the measurement of currents and resistances. Apart from the arrangement, the work is on the whole admirable. It is marked by all the logical sequence and lucidity of exposition of the best French mathematical text books. It lacks, no doubt, the minuteness of detail and abundance of reference which are found in the cyclopædic work of Wiedemann, and we miss the power and grasp, and to some extent the charm, and it must be added also the difficulty of Maxwell's great treatise. But it is better fitted than either of these works to be put into the hands of a student whose mathematical equipment is fairly good, and who wishes to obtain a comprehensive view of the subject without attempting to grapple with its outstanding and peculiar difficulties. It is impossible within the space at our disposal to give an account of the contents of the work, or to attempt anything like a detailed criticism of the manner in which the authors and translator have performed their task. We shall content ourselves with stating a few points which we have noted in the course of a careful perusal of most of the original French edition, and a large portion of the English translation. In an interesting chapter on induction in dielectrics the authors deal with the problem of a dielectric sphere in a uniform field of electric force. An expression for the energy of the sphere in the field on page 167, Vol. I., is found by an erroneous process, which is the more extraordinary as the true value of the energy for the case supposed had just been obtained by an obvious and simple method. The further calculation in which this process is involved professes to consider the energy of a sphere in a variable field; but plainly, as the sphere is supposed so small that the electric force of the field may be taken as uniform over it, the energy must be the same as in the former case. Again, in the discussion of variable flow of electricity (page 225), the result is obtained that if the potential at the sending end of a long cable be kept of constant numerical amount, and made alternately positive and negative for an uneven number of equal short intervals, a maximum of potential at any distance x from the sending end will be obtained at an earlier and earlier epoch as the number of contacts increases. This result is not proved by the analysis given, for if the algebra be carefully gone over it is clear that the expression on the right hand of the equation at the foot of page 225, Vol. I., should have a negative sign prefixed. This connection, indeed, causes a modification of the final equation of the article, which involves the opposite conclusion to that stated. Both of these oversights are repeated in the English translation. The theoretical exposition of the great subjects of magnetism and electromagnetism leave little to be desired. Following Maxwell generally very closely, but with much in the way of commentary and elucidation, the authors give a very full synopsis of the ordinary mathematical theories. Still we miss the suggestiveness of Maxwell's work, and a student who can face successfully the inevitable mathematical difficulties of any thorough treatment of this subject, might after all do better by devoting himself at once to the study of that great masterpiece.

Vol. II. contains an account of various physical measurements involved in electrical processes, chapters on coils and their constants, the measurement of currents, electrometry, comparison of capacities and resistances, magnetic measurements, absolute measurement of resistances, and lastly, industrial applications. Here we think the authors have done more signal service to electrical workers than in their first volume. They have given what must be regarded as the fullest and best arranged account of the processes by which electrical constants are determined which has yet appeared. Generally speaking, the descriptions are clear, and the investigations marked by critical discrimination. Occasionally there is a tendency to too great fulness, and many matters of purely theoretical interest are treated, which might have more fittingly found a place in Vol. I. In this volume also we have noticed some mistakes which are not corrected in the English edition. The description of the bifilar given in chapter iii. is disfigured by two dynamical blunders. In the general case considered at page 64 of an unsymmetrical balance, it is stated that the vertical components of the tensions of the threads are inversely as the distances of their points of attachment above or below from the vertical through the centre of gravity of the body suspended. But this is not the case, for the horizontal components of the tensions, not being applied at the same level, give a couple in a vertical plane as well as one in a horizontal plane, and the former must be balanced by deviation of the vertical components from fulfilment of the condition stated. Again, it is assumed that the shorter thread has the greater tension; but a little consideration shows that this is not necessarily true. On the latter error is founded an erroneous discussion of the equation at the foot of page 65. The chapter on capacities and dielectrics is meagre generally, and markedly incomplete in its treatment of specific inductive capacity. Many of the latest and most important investigations, such as Quincke's and some of Hopkinson's, are not referred to, while those included receive little more than a passing notice. The results given by the latter author for oils are not stated in the English translation. In fact, no additions towards bringing the work down to date have been made in the translation, and this renders the chapter on industrial applications much below high water mark in what is the most rapidly advancing department of physical science. For example, nothing beyond the reports of Messrs. Allard, Joubert, Potier, and Tresca, made in 1882, is given in connection with the efficiency of secondary batteries, and almost all the later works on this subject are defective on this point. We think this chapter ought to be entirely rewritten, and much amplified, at the earliest opportunity. Regarding Dr. Atkinson's translation, we have only to remark that it is well done on the whole. In a few places he has missed the sense of his authors, as at the foot of page 332, where we find the following enigmatical rendering: "When the resistances to be compared are very small, they are put successively as shunts on the coils of the differential galvanometer." The sense of the original is: "When the resistances to be compared are very small, they are put as shunts on the coils of the differential galvanometer joined in series," which is quite clear and intelligible. Many words and terms of expression strike one as decidedly French, as "fictive" for fictitious, "electromotor" for electric generator or dynamo, and many others. These peculiarities excepted, the work of the translator is worthy of all commendation.

IMPROVED METHOD OF STORING WIRE BUNDLES.

WE are indebted to our American contemporary the *Iron Age* for the accompanying illustration showing a method of storing wire bundles, introduced by Mr. Wm. Q. Wales, Boston. The wire bundles are alternately

placed on opposite sides of an upright stick about 5ft. high, and capable of holding about twenty bundles. On the top of this stick the gauge number of the wire is marked. The stick need not be fastened in any manner, as a few bundles will be sufficient to steady it. The advantages claimed for this method are that it is easy to ascertain the number of bundles on the stick, and that it economises space.

GLASGOW INTERNATIONAL EXHIBITION.

ENGLISH STEEL EXHIBITS *(continued from page 583).*—The exhibits of the English steel firms which remain to be noticed are distributed throughout Courts 1, 2, and 3, situated on the south side of the east corridor. Messrs. Cocker Brothers, Limited, of Sheffield, have a well arranged display of their manufactured steel specialties, at the south end of Court 1. As the bulk of the articles shown belong to Class VIII., devoted to cutlery, ironmongery, &c., it is only necessary to direct attention to the assortment of tool steel bars, and the fractures showing the different grades of steel arranged in a glass case at the rear of the stand.

Messrs. Jowitt & Sons, of Sheffield, have an open stand in the same court. They exhibit a large number of bars of various sections of their well known beam engine brands of cast and double shear tool steel, some fine blades for large plate shearing machines, and a splendid collection of files and rasps of all sizes, and of every possible variety of cut.

The West Cumberland Iron and Steel Company, Limited, of Workington, are represented by a glass case in Court 2, containing numerous samples illustrating the manufacture of hematite pig iron, Bessemer and Siemens steel, rails, sleepers, and plates. On the top of the case is a remarkable collapsed steel boiler tube. This is a length cut from the flue of a boiler which was allowed to run short of water while working at a colliery in the Midlands a few years ago; and the amount of buckling which the plate has undergone without fracture demonstrates the excellent quality and toughness of the steel. Beside the damaged flue is a ½in. steel plate, which has been exposed to the fire of Martini rifle bullets at ranges of 100 and 200 yards, and also bulged by the explosion of ½lb. of dynamite on its surface. The indentations produced by the impact of the bullets resemble marks which would be made by the use of a large and rather blunt centre punch. Of the objects inside the case a pressed steel gong suspended in a frame of twisted bar steel, and mounted on a steel railway sleeper, first attracts the eye. The gong and its supporting stand are turned and polished, and are interesting as examples of ingenious workmanship, but it is not clear what special characteristic of steel this portion of the exhibit is intended to illustrate. A large number of the different rail and tramway sections rolled by the company are shown, and also some good specimens of cold twisted and bent heavy rails, and a rail tested by a 10cwt. ball falling from heights of 12ft., 13ft., 14ft., and 16ft. A peculiarly shaped sleeper fitted up complete for the Southern Mahratta Railway Company of India; a section of the same before receiving the final pressing, and a section of a Midland Railway Company's steel sleeper, are also of interest to railway engineers. Broken tensile test pieces, with breaking stresses ranging from 28 tons to 31 tons per square inch, and elongations up to 26 per cent.; and a collection of small steel plates of different thicknesses twisted, drifted, and dished cold, prove the quality of the Bessemer and Siemens steel plates manufactured by the firm. Mr. Snelus, the general manager, has always been a strong advocate for the claims of Bessemer steel; and though the Siemens process is now also worked, the company have long enjoyed a high reputation for the production of reliable plates by the older method.

The Ebbw Vale Steel, Iron, and Coal Company, Limited, of Ebbw Vale, Mon., have a large and handsome stand in the same court, consisting of an oblong horizontal case, with a narrower vertical case rising from its centre. The whole is supported on a frame of heavy channel steel resting on short pillars formed of coiled bar steel. The lower case is partitioned off into a number of divisions, containing sections of Welsh bar iron, steel sleepers, tram rails, steel channel bars, tees, angles, and fish plates: tested fish plates, rail joints of all sizes, and specimens of puddled bar, forge and Bessemer pig iron. Below the stand are two of Rafarel's patent steel sleepers, one fitted up complete with chair and suspended rail, and the other with fastening chair and cushion; a steel sleeper for the East Argentine Railway; and one for the Indian State metre gauge railway. On the top of the lower case, resting on a shelf surrounding the base of the upper one, are some fine samples of twisted rails and heavy bars, and a piece of one of the first rails rolled at the Ebbw Vale Works in 1830. In the upper case there are numerous sections of double head, bull head, flanged, and tram rails, weighing from 9lb. to 80lb. per yard, which serve to illustrate the designs of both home and foreign engineers. A collection of steel channel sections is also shown, and one of these, measuring 10in. by 3¼in. by ⅜in., is the thinnest large channel bar yet rolled. All the steel exhibited is the product of the Bessemer converter, and it is interesting to recall that it was at the Ebbw Vale Works that the decarbonisation systems of Martien and George Parry, which in a sense were the precursors of the Bessemer process, were tried; and that steel produced by Parry's method was here rolled into rails before any—by the Bessemer process—were made in England. Mushet made several of his famous experiments to determine the influence of manganese on iron and steel at these works, and here also spiegeleisen was first made on a commercial scale in Britain. It may also be of interest to note that the Ebbw Vale Company started their first blast furnace so far back as 1780; and that in the year ending March, 1888, the output from the different departments amounted to 180,000 tons of pig iron, 120,000 tons of Bessemer steel, and almost 10,000 tons of iron bars, besides large quantities of iron castings, coke and bricks, and about 1,000,000 tons of coal.

Messrs. Seebohm & Dieckstahl's exhibit, in Court 3, takes us back to the old Huntsman crucible steel process, which for a century and a half has maintained its supremacy in the manufacture of the finest and most expensive qualities of steel. Mr. Seebohm, in a paper read a few years ago at the Chester meeting of the Iron and Steel Institute, somewhat ruffled the complacency of his audience by stating that, in spite of the advances made in metallurgic chemistry, there yet remained peculiar circumstances in connection with such an apparently simple matter as the making of crucible steel, upon which chemical analysis could throw no light. This view did not meet with much approval; but the fact remains that the best steel for cutting purposes can only be produced at the present day by closely following the methods which have been in use for more than a century. This firm, at the Dannemora Works, Sheffield, manufacture the best qualities of cast steel; and their neat show case contains a most interesting collection of bars and fractures of Swedish iron, cast steel ingot fractures, and an assortment of finished bars, to illustrate the different stages of manufacture. Fractures of tool steel bars with varying contents of carbon, and a variety of small tools made from various descriptions of steel, are also shown. We may note as specially worthy of examination the beautiful fractures of the Dannemora self hardening cast steel, the fractures of mild centred steel, and twelve small blocks of tempered steel, showing the gradations of colour produced by tempering.

The Consett Iron Company, Limited, of Blackhill, Durham, have in the same court a well arranged exhibit, which, though small as compared with some of the stands in the machinery section, is in several respects one of the most interesting metallurgical collections in the Exhibition. The various articles are arranged in tiers, and conspicuous on the top of all is a steel "cobble" plate—that is, a plate which has been crumpled by accidentally catching some fixed part of the plate mill when being passed through the rolls. Round the "cobble" are grouped some fine pieces of Durham coke, of which the company are able to produce 500,000 tons yearly; masses of raw and calcined Cleveland ironstone, Algerian ore, and furnace slags, with a row of chequer plates as a background. A step lower are ranged a number of small chequer plates of different pattern, numerous Siemens steel cold tests of various kinds, and several samples of pig iron, which the seven blast furnaces at Consett make when fully employed at the rate of 220,000 tons per annum. The next tier contains steel plates folded hot in a variety of ways; some excellent samples of thin bulged plates, both whole and cut in halves to show the reduction in thickness produced by the extension of the metal; hot folding tests of all kinds, twisted bars, and a number of broken tensile test pieces, showing the strength and ductility of the steel. A steel ingot, about 14in. square, broken through the middle, exhibits a sound and homogeneous texture. On the lowest ledge, and resting on the floor, are several plates bulged hot into the shape of Welsh hats, more than a foot deep; some excellent examples of flanged work; a steel bloom broken through, to show the grain; and a variety of tests showing the quality of the steel made by the firm. The manufacture of steel was only commenced at Consett a few years ago; but the company had for a long time previously been favourably known as iron plate makers, and until recently 175 puddling furnaces were at work. Before the use of steel became so general, from 85,000 to 90,000 tons of iron plates were made annually. This has declined to about 25,000 tons, while the output of steel plates is now about 100,000 tons. The steel plant consists of sixteen large Siemens furnaces, powerful cogging mills with bloom shears for converting ingots into slabs, and four splendid plate mills, with the necessary heating furnaces and gas-producing plant. The works are exceptionally well arranged, and are probably the finest of the kind in the world. Photographs of the Consett blast furnaces, and of the Orconera and Carmen mines, near Bilbao, placed at the sides of the stand, remind us that this company were among the first to adopt the Whitwell hot blast stove, and that the hematite ore used for conversion into steel comes from the firm's own property in Spain.

The only remaining exhibit which calls for any mention in this article is a small case forming part of Messrs. Palmer & Co.'s large marine stand, in the main avenue. This firm added the manufacture of steel to the other branches of their extensive business about two years ago, adopting what is now called the "Batho" open hearth furnace. They show a selection of cold tied steel bar knots, dished and double-dished plates, and numerous other specimens which, while not calling for special mention, afford sufficient indication of the excellent quality of the steel produced at the Jarrow works.

THE SCOTCH STEEL EXHIBITS.—Viewing the magnitude and importance of the Scotch steel industry at the present time, it is curious to note that even its immediate precursor, the iron industry, is of comparatively recent introduction into the country, and cannot in any sense be considered an anciently established business. About the middle of the 18th century, there existed smelting furnaces for charcoal iron near Goatfield and Bonawe, in Argyleshire, both, however, on a very minor scale. The establishment, in 1759, of the famous Carron Iron Works, near Falkirk, by Dr. Roebuck, was practically the first attempt to introduce the making of iron on anything like a large scale into Scotland. These works, in whose construction John Smeaton, the eminent engineer, took part, are still in existence, and to the fact that small cannon were amongst their earliest products is derived the origin of the term "carronade." In 1780, Wilsontown Iron Works, near Shotts, were erected, and there, in 1804, the first rolling mill in Scotland is stated to have commenced operations.

Turning now to the Scottish steel industry proper, we find that the manufacture of crucible steel—in which, according to Mr. James Riley, some six firms are at present engaged in Scotland, with a combined output of some 1500 tons per annum—was the earliest and, at one time, the only steel produced north of the Tweed. It was not till 1857 that an attempt was made, but unsuccessfully, at Coatbridge, to introduce the Bessemer process into Scotland; a similar experiment shortly after, at Govan, ended in no better results. Some four years later, Messrs. Rowan again grappled with the problem; but after a struggling existence, prolonged until 1875, their works were dismantled and closed. This brings us to the founding of the Steel Company of Scotland, Limited, who have been truly termed the pioneers of the Scotch steel industry. Commencing at Hallside in 1873, with four furnaces each of 6 tons capacity, the company produced steel rails only. In 1877 a plate rolling mill was laid down and brought into successful operation at Hallside. And now followed a marvellous development of the steel plate and bar industry. With increased demand followed an enormous expansion of productive power. The same year saw Messrs. Beardmore & Co., of Parkhead Forge, also Messrs. Williams & Co., of Wishaw, erect furnaces for steel making. In the following year large additions were made to the Steel Company of Scotland's Hallside Works, whilst their purchase of the works at Blochairn, which were forthwith converted for steel manufacture, increased to a very appreciable extent the productive power of the company.

In 1883, over seventy furnaces were in operation in the district, with an annual output computed to exceed 230,000 tons. The rapid development of the steel industry cannot be better illustrated than by quoting the following remarkable figures, viz., in 1873 an output of 1200 tons; in 1885 an output of 241,074 tons; in 1886 an output of 244,900 tons; whilst for the current year a considerable increase will doubtless be seen, for at the time we write, and for some months past, the whole of the works in Glasgow and its neighbourhood have been well supplied with orders, and working up to the fullest capacity. Several new works are in course of construction, and others are understood to be projected. The Scottish steel trade may generally be reported as enjoying a full measure of business and prosperity.

Coming now to the manufacture of open hearth steel, the furnaces in common use hold about 15 tons, but range up to 25 tons, with corresponding dimensions. A furnace will yield two charges per day of twenty-four hours. Before leaving the works of the manufacturers the steel generally is subjected to a series of specified tests by inspectors appointed by the Admiralty, the Board of Trade, Lloyd's Registry, and the Bureau Veritas, according to the ultimate destination of the material. Foreign Governments send their own officers when testing material, and in the case of bridge work, &c., the Engineer-in-Chief is represented by a member of his staff. The bend test pieces are from 1½in. to 2in. in breadth, and usually some 9in. long, and are divided into two classes—cold bends and temper bends. The former are bent without any further treatment; the latter, however, having been heated to a dull cherry red, are cooled in water having a temperature of about 82°F. previous to bending. The utmost method and order has to be observed in numbering the different test pieces, and so perfect are the systems adopted that the history of any particular plate or bar can be traced back to its original charge long after it has left the manufacturer's hands. The following are amongst the principal tests required:—

British Admiralty—Tensile test: Strips cut length-

Digitized by Google

wise to have an ultimate tensile strength of not less than 26 tons and not exceeding 30 tons per square inch of section, with an elongation of 20 per cent. in a length of 8in. Bending test: Strips cut crosswise or lengthwise 1½in. wide, heated uniformly to a low cherry red, and cooled in water 82°F., must stand bending to a curve of which the inner radius is one and a half times the thickness of the steel tested. The ductility of every plate, is to be ascertained by the application of one or both of these tests to the shearings, or by bending them cold by the hammer. One plate to be taken for testing from every invoice, provided the number of plates does not exceed fifty. If above that number, one for every additional fifty or portion of fifty. Steel may be received or rejected without a trial of every thickness on the invoice. Foreign Governments as a rule adopt the test requirements of the British Admiralty.

Board of Trade.—For marine boilers: Tensile test for furnace plates and plates exposed to flame, 26 to 28 tons per square inch, with 20 per cent. elongation in 10 inches. Shell plates and plates not exposed to flame, 28 to 30 tons per square inch, with 20 per cent. elongation in 10in. The tensile strength and elongation are stamped on every plate. The bending tests are closely identical with those required by the British Admiralty.

Lloyd's Register.—Tensile test: Boiler plates, 26 to 30 tons per square inch and 20 per cent. elongation in 8in. Ship plates, 27 to 31 tons per square inch and 20 per cent. elongation in 8in. Ship angles and beams, 27 to 33 tons per square inch and 16 per cent. elongation in 8in. A tensile test from each charge is required. The bending tests are similar to those already set forth.

Bureau Veritas.—Tensile tests: Ship and boiler plates, angles, &c., 27 to 32 tons per square inch, with 20 per cent. elongation in 8in. Temper bend tests are made as already stated.

Civil engineers and others ordering steel are accustomed to issue their own specifications, dictated by the particular class of work for which the material is required. Thus, for example, the steel for the Forth Bridge is specified to have an ultimate tensile strength of 30 to 33 tons per square inch, and 20 per cent. elongation in 8in. for steel subject to tensile strains; and an ultimate tensile strength of 34 to 37 tons per square inch, and 17 per cent. elongation in 8in., for that portion of it which will be in compression. Temper and cold bend tests from each slab or bar are required to stand the British Admiralty specifications. The rivet sheet is specified to have an ultimate tensile strength of 26 to 30 tons per square inch, and 20 per cent. elongation in 8in., with bending tests as already given.

Having given a brief sketch of the iron and steel industry, we will now direct attention to the various steel exhibits. The Steel Company of Scotland have bestowed great pains on their exhibit, and the magnificent trophy they have reared forms in itself a monument of the Scotch steel manufacturing industry. The exhibit is square in plan, and has been tastefully designed as a canopied pavilion, every portion being formed of some plate, bar, or angle, made by the company. At one side is shown a steel marine engine column, weighing 6 tons, as supplied to the s.s. "City of New York," and near it is a collapsed steel boiler flue from the s.s. "County of Durham," exhibiting the marvellous tenacity of modern mild boiler steel. An exhibit which will, however, especially claim the attention of those interested in the steel industry, is a plate 18in. by 5in., no less than 130ft. long, curled up to facilitate transport. Specimens of dishing by means of explosives are also shown; the plates under which 8oz. of dynamite were fired exhibiting no failure or distress of any kind. A severer test could scarcely be imagined. The reeled bars for shafting, from the company's specially constructed reeling mill at Hallside Works, are remarkable for finish and tough skin.

Riley's patent welded steel pipe introduces a novelty which may some day revolutionise the whole pipe making industry. At present cast iron pipes are almost exclusively employed in this and other countries for gas, water, and sewage works; and only in localities to which the transport is particularly long and difficult have wrought iron and steel pipes been introduced, on account of the great saving in weight. So far the greater tendency to corrosion on the part of steel, as compared with wrought iron, has militated against the former when cast iron, though cheaper than both, was inadmissible; but this difficulty has, we understand, been met and successfully overcome.

Rolled blanks for eye bars are of particular interest, and a short description of their manufacture by a specially designed plant may be of value to the professional reader. Six rolls are employed, two main horizontal rolls and four side vertical ones; the former about 18in. diam., the latter about 9in. diam. The bar is first rolled down to a uniform thickness of 5in. throughout, the lower roll is then raised by means of a hydraulic cylinder beneath it (having a diameter of 11in., and a pressure of 1000lb. per square inch), the usual screw arrangement for tightening the rolls not being sufficiently powerful when the bar is between the rolls, and when rolling is continued until the requisite thickness is obtained. It is somewhat difficult to stop the engine at the right moment at the end of each pass, as the bar of course grows longer at each turn through the rolls. Another practical difficulty is to start with a billet of the right size, so that when the finished thickness, say 1¼in., is reached, the bar may be of the required length also. After rolling, the ends of the bar are re-heated, and the scrap ends are sheared off hot. The bars are then dispatched, and, after the eyes have been forged at the girder builder's, the bars are annealed. The Steel Company's foundry at Newton is well known for its excellent steel castings, the results of many years of patient labour on the part of Mr. Riley. A cast steel engine frame, as supplied to H.M.S. "Pheasant," shows to what perfection an intricate and difficult steel casting can be turned out. Specimens of spur and other tooth wheels, including bevelled gearing, exhibit the same high class finish. A cast steel piston is also shown amongst other exhibits of the same class of material. A variety of rail sections, tramway rail sections, angles, channels, T bars, and bulbs, are exhibited, which call for no special remark; and the numerous excellent specimens of bends, knots, &c., are also familiar to our readers. They abundantly maintain the high reputation built up by the Steel Company of Scotland.

The Hallside Works of the same company, started in 1872, are situated at Newton, a small village some six miles east of Glasgow, and cover the original seat of the company, who did not acquire their present Blochairn Works till some years later. Originally comprising but eight Siemens furnaces, these works now contain no less than twenty-two furnaces (capable of turning out 80,000 tons of ingots yearly). In addition to this, there are one 28in. cogging train, one 26in. train for rails and heavy sections, two 26in. plate mills, one 18in. mill for light sections, and one 14in. mill for bars. The foundry for steel castings has given them a world-wide reputation for stern frames, rudders, crank shafts, &c., and generally all those varied parts of ships and machinery for which cast steel has proved its suitability and superiority. The Blochairn Works, originally built for the manufacture of iron, were purchased in 1880 by the Steel Company of Scotland, and by them adapted for steel production. The system of working is identical with that pursued at the Hallside Works, differing only from it in unimportant details arising from local surroundings.

Messrs. David Colville & Sons, Dalzell Steel and Iron Works, Motherwell, have arranged an exhibit of great interest—a series of steps, laden with specimens and samples, which have been tested in every conceivable manner, and subjected to the severest trials; is surmounted by a 10ft. diam. steel boiler end plate, bearing the well known Dalzell brand. The raw materials shown will be examined with interest; and the steel in the earlier stages of ingots and billets, specimens of which are arranged in the trophy, form an instructive connecting link with the finished plates shown above. Messrs. David Colville & Sons' works, known under the name of the Dalzell Steel and Iron Works, are situated at Motherwell, a short distance from Glasgow. Originally established about the year 1871 for the manufacture of iron, that of steel was subsequently added, and now forms the principal output.

Messrs. Wm. Beardmore & Co., Parkhead Forge, Glasgow, exhibit steel forgings for marine purposes, which in quality of material, excellence of finish, and execution, fully maintain the reputation of this old established firm. A hollow steel propeller shaft for the Royal Italian warship "Re Umberto," 21⅓in. diam. by 37ft. 2½in. long, the hole being 13½in. diam., and weight 13 tons, is carried on two 6-ton ingots. A test piece is also exhibited from the shaft, which gave an ultimate tensile strength of 28·8 tons, and an elongation of 28 per cent. at fracture on a length of 8in. Messrs. Beardmore also exhibit a hollow steel built single crank shaft for the s.s. "Seamew" 14¼in. diam., 7ft. 10½in. long, with a 3in. hole through the centre. The weight of the ingots employed being 16 tons 6cwt., —that of the finished shaft 4 tons 17cwt. A sample tested for tensile strength giving 28·7 tons per square inch, and 27 per cent. elongation on 8in. at fracture. A model in wood is also shown of the hollow steel crank shaft for the before-mentioned Italian warship, having the following dimensions: 19⅓in. diam. by 9ft. 6in. long (with 9½in. hole through centre); weight, 7 tons; 28·5 tons strength per square inch of material; and 26 per cent. elongation on 8in. Another large exhibit by the same firm is a steel triple crank shaft, 15¼in. diam. by 21in. long, and weighing 17 tons, with 28·5 tons tensile strength, and 25 per cent. elongation on 8in. length. Messrs. Beardmore also exhibit a handsome model in wood of their slabbing hammer "Samson," with 48in. cylinder, 6ft. stroke, and capable of delivering a blow equivalent to 400 foot-tons. An interesting exhibit, and one well illustrating the remarkable ductility of rivet steel, are the words "Wm. Beardmore & Co." in bold round hand, the letters being formed by a continuous bar of ¾in. steel 70ft. in length. A long display of small articles of interest—knots, bends, paper weights, even a model of a high hat in steel, will be examined with interest; and all demonstrate the wonderful capabilities of mild steel, and the severe treatment to which it may be subjected without exhibiting distress of any kind. Some interesting photographs of mild ingot steel crank shafts are worthy of attention, also a railing formed by the torsion of a cold steel bar 1 5/16in. square by 19ft. 9in. long is an interesting and clever piece of work.

(To be continued.)

TREATMENT OF SEWAGE BY THE IRON PROCESS.

Mr. Conder's method of sewage treatment has now had some few years of trial, and he has summed up the advantages which are claimed for it in a paper which has recently been published in the collected professional papers of the corps of the Royal Engineers (No. XIII., page 1 *et seq*). The process consists simply in the local use of sulphate of iron to clarify and partially decompose the sewage. This property of sulphate of iron has been known for many years, but Mr. Conder deserves credit for showing how a solution of this substance can be easily used and applied locally. The instrument for effecting this purpose is called by the inventor a "ferrometer," and consists essentially of a box in which crystals of iron sulphate are stored, and which slowly dissolve in a current of running water which passes through the apparatus. In this way a solution of the deodoriser of tolerably uniform strength is obtained, and is added automatically to the water in urinals and sinks from time to time. If sufficient of the solution be added, a considerable amount of the organic matter is precipitated, and the effluent water will be correspondingly less foul. The sulphate of iron does not only act as a precipitant of the sewage matter, but, in addition, by being a carrier of the oxygen of the air, a certain amount of oxidation and destruction of the sewage matter is at the same time brought about. It must not be forgotten, however, that this oxidation of the ferrous sulphate causes a separation of a precipitate of the higher oxide of iron, which must be removed from time to time from the pipes and sewers in which this system of purification is employed. The system has been tried on a small scale at Chichester Barracks and at Windsor Castle, and the sanitary authorities at Guildford have also been induced to give a somewhat more extensive trial to the new process. Mr. Conder is of opinion that his method will be found both cheap and effectual, and we are inclined to admit that some such local treatment of foul and polluting liquids at the moment of formation will be the final solution of the much debated sewage problem. It has been recently proposed that a dilute disinfectant fluid, such as a solution of manganate or permanganate as is now used by the Metropolitan Board of Works at the sewage outfall, should be supplied to householders for flushing and cleansing purposes, and that, by thus rendering the sewage harmless as it is produced, the cost and trouble of dealing with large quantities of the material would be avoided. Both sulphate of iron and the manganate solutions just alluded to, although more costly than bleaching powder, have the advantage of being perfectly odourless, which commends the extension of their use locally, and until Mr. Dibdin and other advocates of the manganate treatment of sewage have found a suitable means of distributing and using their disinfectant in each house, we hope that Mr. Conder's ferrometers may be used.

SUGAR REFINING.

On Monday, the 4th inst., at a meeting of the Society of Chemical Industry, held at Burlington House, a paper, by Messrs. B. and J. Newlands, was read upon "The Mode of Using Char in Sugar Refining." The paper set forth that the charcoal used in experimenting was not new, but had been used for some time in sugar refining. New charcoal would not get rid of the colour in the sugar solution. Dried blood and horns give a charcoal of great decolourising power for oils and fats, but not suitable for sugar refining. For the latter, a charcoal is required which is both hard and porous, and one which adheres strongly to the tongue; when the charcoal is not sufficiently hard, it causes inconvenience by the production of dust. The following table shows the amount of dust produced after each sample of charcoal had been revolved 672,000 times, and then sifted:—

	Size of Sieve.	Dust produced Per cent.
English charcoal (No. 1)	10 to 20	2·560
" " "	20 to 30	2·560
" " "	40 to 50	3·220
" " (No. 2)	20 to 30	1·414
" " "	30 to 40	3·694
" " "	40 to 50	8·720
Russian charcoal	8 to 10	3·878

Digitized by Google

Most refiners like a "small grist" char, since it is most efficacious in decolourising sugar, and the following table gives the results of experiments on that point. The amount of reduction of colour in each case was determined by means of a photometer:—

Size of Sieve.	Proportion of colour remaining.
Char 10 to 20	5
„ 20 to 30	4
„ 30 to 40	3·5

Original colour 23·0

The higher the temperature within certain limits the better are the decolourising results:—

Temperature, Fahr.	Proportion of colour remaining.
100	64
125	58
150	46
175	32
200	32

Original colour 420.

Time is a matter of importance, and six hours gives the best results in the case of cane sugar. Beet sugar is better with longer contact. The authors had obtained the following results in time experiments with three descriptions of sugar:—

	Jamaica.	Natal.	88 Nat. beet.
Original colour	660	420	23

Proportion of Colour Left.

Hours.	Jamaica.	Natal.	88 Nat. beet.
2	102	60	6
4	92	37	5½
6	60	28	5
8	64	29	4½
10	—	30	—

The colouring matter which char abstracts from sugar can be dissolved out of the char again by alkaline solutions, consequently the char does not act by destroying the colouring matter by peroxide of hydrogen or any other oxidising agent.

The absorption of air by freshly burnt bone charcoal goes on for a considerable time; for if some freshly burnt charcoal be put in a bottle, and turned out of it a few days afterwards, a thermometer then put in the mass will rise 20° or 30°F., showing that absorption is going on. In sugar refineries the char after use is washed with once or twice its weight of water, and then re-calcined in closed cylinders. At first steam is driven off from it, and this steam is utilised for the drying of wet charcoal. "Buchanan's Improved" kiln is one of the best forms of pipe kilns for revivifying charcoal.

Notes.

PHOTOGRAPHS OF LIGHTNING.

At the last meeting of the Royal Meteorological Society the first report of the Thunderstorm Committee was read. This deals with the photographs of lightning flashes, some sixty in number, which have been received by the Society. From the evidence now obtained, it appears that lightning assumes various typical forms under conditions which are at present unknown. The committee consider that the lightning flashes may be arranged under the following heads: 1, Stream; 2, sinuous; 3, ramified; 4, meandering; 5, beaded or chapletted; and 6, ribbon lightning. In one of the photographs there is a dark flash of the same character as the bright flashes; but the committee defer offering any explanation of the same until they get further examples of dark flashes. As the thunderstorm season is now coming on, the committee propose to publish their report at once, along with some reproductions of the photographs by the autotype process, in order that observers may be prepared to notice the various forms of lightning.

THE SWEDISH IRON TRADE.

In a report to the Foreign Office on last year's trade at Gothenburg, Consul Duff states that there was a steady decline in the price of Swedish iron, which was partly due to the greater use of the Bessemer and Martin processes having lessened the demand for Swedish make. Swedish Bessemer, of which some years ago considerable quantities were shipped, has by degrees gone out of demand in the Sheffield market, and only small lots are now exported. Several works have now adopted the Martin process instead. Previous to 1887, the State railways were large importers of rails; but they are now buying most of what they want at home, so that the imports have fallen from 10,563 tons in 1886 to 5859 tons in 1887. The manufacture of machinery and implements in Sweden is making great progress, and the imports have been gradually declining during the last four years. The Consul says that the iron shipbuilding yards on the river at Gothenburg have turned out some excellent steamers.

MINING IN CUBA.

Vice-Consul Ramsden, of St. Jago de Cuba, states that an American company, with a capital of £400,000, is working some iron mines in Cuba at a large profit. A second company, also American, has just bought up another section of mines of the same ore, a third is at work on the manganese deposits, and a fourth has contracted for the well known copper mines at Cobre, renting them and the railway. Mr. Ramsden considers that there is every prospect of Cuba becoming a great mining centre, as the country and its enormous resources become better known.

ECCLESIASTICAL ART EXHIBITION.

Definite arrangements have now been made for holding the Tenth Annual Ecclesiastical Art Exhibition at Manchester, a suitable building having been secured. Many of the leading church furnishers, embroiderers, silversmiths, and glass painters will be represented, and educational works and appliances will also be included in the Exhibition. The loan collection will embrace goldsmiths' and silversmiths' work, ancient and modern, and ecclesiastical metal work in general; embroidery, needlework, tapestry, wood and ivory carving, ecclesiastical furniture paintings, drawings, architectural designs for churches and schools, photographs, books, and MSS., and other books of archæological interest belonging to the churches of the diocese.

MAGAZINE WEAPONS.

It appears from the last report by the Chief of the Ordnance to the United States Secretary of War, that the Americans are in no hurry to adopt a magazine rifle. General Benét says: "An effective and simple magazine gun has become a necessity, and we have been seeking for one that would be satisfactory to the army; but thus far without success. From the little that can be learned from the magazine systems said to have been adopted abroad, I am persuaded that nothing is to be gained by haste at this juncture; but that the Springfield arms will continue to admirably suit our purpose, and the best interests of the army, long enough to enable us to determine upon, finally, a magazine gun that will do credit to the inventive genius of our people."

ENGLISH GROWN TOBACCO.

We recently received from Messrs. Cope Brothers and Co., Limited, Liverpool, a sample box of tobacco which has been grown by Messrs. James Carter & Co., seedsmen, at a farm in Kent, and was cured by Messrs. Cope. It is stated that this crop is one of the first experimental crops brought to maturity and passed through the various stages of manufacture since the time of Charles II. Ever since tobacco growing was attempted in England its culture has not only not met with Government support, but has been actually prohibited, so that the few attempts formerly made had to be carried out in opposition to the law. Last year the Government were asked to allow the extensive experiments of which the present crop is the result. The rearing of the tobacco plant appears to be comparatively easy; but a much more serious difficulty seems to be the current Excise obligations. The other day the Chancellor of the Exchequer was questioned in the House of Commons on that subject, and he stated, after a few humorous remarks as to the quality of the tobacco, and to providing samples of it in the smoke room for trial, that any relaxation of the fiscal regulations which would injure the revenue was impossible.

NEW AMERICAN CRUISER.

The new cruiser "Texas," being built for the United States Government in the Navy Yard, Norfolk, Va., has her vital parts protected by a belt of armour and an underwater armour deck extending from the belt to the extremities of the vessel. She has twin screws. The principal dimensions are: Length between perpendiculars, 290ft.; extreme breadth, 64ft. 1in.; depth moulded to upper deck, 39ft. 8in.; mean draught, 22ft. 6in.; displacement, 6300 tons; displacement per inch at load line, 30 tons. Complement of officers and men, 300. Maximum speed, 17 knots. The main armament consists of two 12in. guns in turrets, and six 6in. guns protected by shields. The secondary battery consists of four 6-pounders, four 8-pounders, and four 47mm. revolving cannon, protected by 1½in. steel plating; two gatlings and two 37mm. revolving cannon. Two 1-pounders, two gatlings, and two 37mm. revolving cannon are placed in the military mast tops, to repel boarders and torpedo boats. Two 37mm. rapid-firing guns are fitted to the steam cutters. There are six torpedo tubes. The engines are triple expansion, placed in separate water tight compartments. The coal supply is 500 tons, and the endurance for a speed of 17 knots is 1110 knots. The ship has double bottom and transverse water tight bulkheads, and is built with vertical and flat keel plates, and there are longitudinal stiffeners for bottom and bilge.

SUGAR MACHINERY.

The British Vice-Consul at St. Iago de Cuba, in a Foreign Office report, states that the sugar estate machinery in use in Cuba is obtained from England, the United States, and France. He says the English sugar mills are found to be the strongest and best, but the French evaporating apparatus is preferred to and found to work better than the English. The general class of machinery made in the United States for export is, in his opinion, unreliable, being simply made to sell, though that used in the American refineries is unrivalled. Small machinery is often ordered from the United States instead of from Europe, on account of the greater promptness with which delivery can be obtained. At present there are two appliances for use on sugar estates for which there should be a good future, viz., cane shredders and furnaces for burning green bagasse. Though there are several in the market, none have so far given universal satisfaction, and the report states that there is a field for really good articles of this kind.

THE EFFECT OF RUSSIAN CUSTOMS DUTIES ON BRITISH TRADE.

The increases which are constantly being made in the Russian tariff are having, as is only to be expected, a serious influence in preventing imports into Russia, and German trade has suffered severely in consequence. Consul-General Grant, of Warsaw, in reporting on the trade of last year, points out that business with Great Britain has also decreased, there being a noticeable falling off in fancy cloths, Manchester cotton velvet, jute, felt carpets, cocoanut mattings, Nottingham curtains, leather and cotton beltings, Birmingham goods, Sheffield cutlery and tools, agricultural machinery and implements, leather for bookbinders, earthenware, and glass. There is also a decrease in cotton yarns and twist, knittings, Irish linen, chemicals, and aniline dyes. The only articles which seem to have held their own are power looms and spinning machinery. The Consul-General states that in consequence of the diminished importation of foreign manufactured goods, many small manufacturers in Warsaw have lately taken to producing articles which were formerly obtained from abroad, such as pins and needles, leather goods, umbrellas, cravattes, silk ribbons, stays, &c.; also silk, cotton, woollen, and kid gloves; felt and straw hats, small iron wares, tin goods, buttons, ready made clothes, knitted goods, musical instruments, toys and dolls, basket goods, and carpets. Warsaw is, in consequence, rapidly becoming an industrial centre.

THE FORESTS OF EUROPE.

The *Times* states that the French Ministry of Agriculture has just issued some interesting statistics respecting the distribution of forest in Europe. The total area of Europe laid out in forest—exclusive of Turkey, Bulgaria, Bosnia, and Herzegovina, omitted in the official statement—is set down at 286,989 million hectares, or about 708,862 million acres; that is, about 18·7 per cent. of the total area of Europe is forest land. In proportion to its total area Great Britain and Ireland has of all countries in Europe the least extent of forest, amounting to only 4 per cent. of its surface, and in proportion to the number of its inhabitants enjoys by far the least allotment of forest, amounting to only 0·036 hectare, or 0·089 acre—*i.e.*, considerably less than the tenth of an acre to each inhabitant. The country in Europe next lowest in the forest scale is Denmark, with 4·8 per cent. of forest land, or 0·09 hectare to each inhabitant. The third of the countries of Europe in the ascending forest scale is Portugal, with 5 per cent. of forest land and 0·11 hectare to each inhabitant—*i.e.*, an average of three times the amount of forest land to each inhabitant of Portugal that is allowed to each inhabitant of the United Kingdom. Holland has 7 per cent. of forest land and 0·05 hectare to each inhabitant, or about one and a half times as much as to each inhabitant of the United Kingdom. The country in Europe possessing most forest is Russia in Europe, with 200,000 million hectares—*i.e*, 37 per cent. of its whole area and 3·37 hectares to each inhabitant—that is, each inhabitant of Russia in Europe has an average of nearly ninety-four times the extent of forest land allotted to each inhabitant of the United Kingdom. In its percentage of forest land and the amount of forest to each inhabitant, Sweden, however, stands still higher. With 17,569 million hectares of forest, Sweden has 39 per cent. of its land in forest, and so 3·84 hectares of forest to each of its inhabitants. Norway, with 24 per cent. of its area in forest, allows each of its inhabitants an average of 4·32 hectares forest, or 120 times as much as is allowed to each inhabitant of the United Kingdom. Hungary has 29 per cent. of its area in forest, or 0·58 hectare of forest to each inhabitant. France possesses 9888 million hectares of forest, or 17·7 per cent. of its total area, and so allowing 0·25 hectare of forest to each of the inhabitants—nearly seven times as much as is allotted to each inhabitant of the United Kingdom.

Patent Record.

Compiled from "The Official Journal of the Patent Office," by W. E. Heys, *70, Market-street, Manchester.*

APPLICATIONS FOR PATENTS.

(The names in italics within parentheses are those of Communicators of Inventions.)

ENGINEERING.

15th June, 1888.

8756. Price, J. ..... Dredging apparatus.
8758. Forsyth & Coleman ... A power machine.
8763. Morris & Hatch ..... Sight feed lubricators.
8767. Crawford, T. ..... Apparatus for forming railway cuttings and quarrying.
8773. Hattersley & Hill ... Shuttle operating mechanisms for looms.
8774. Clegg, J. ..... Backing-off motion of mules.
8775. Kenyon, J. H. ..... Looms.
8776. Catlow, C. ..... Looms.
8778. Carey, W. ..... Underground engines.
8780. Rees, D. ..... Machine for moulding fire bars.
8781. Cross, E. ..... Prevention of accidents and breakdowns in mules.
8783. Evans, R. ..... Pressing scrap metal.
8785. Pittis, J. A. ..... Machines for cutting and arranging match splints.
8789. Burgess, G., & others... Automatic regulator for sectional warping and beaming machines.
8793. Dost, C. O. ..... Mills for grinding corn.
8800. Lorenz, W. ..... Circular revolving slide rest.
8811. Rosicky, J. ..... Scutching machines.
8814. Treeby, A. ..... Magazine small arm.

16th June, 1888.

8819. Sayer, R. C. ..... Aërial railways.
8820. Kay, J. ..... Combined slotting, shaping, milling, drilling, and boring machine.
8823. Storrar, J. M. ..... Candle making machines.
8826. Gallimore & Brooks... Apparatus for measuring yarn and thread in winding, reeling, balling, and similar machines.
8827. Smith, W. ..... Shuttle box motions of looms.
8831. Chatham, E. ..... Crushing and mixing mortar.
8832. Leane, G. H. ..... Constructing buildings in alluvial soils.
8841. Ferguson, F. O. ..... Propelling and steering boats.
8843. Norridge, F. ..... Raising water by pulsometer.
8844. Evans, P. ..... Manufacture of steel.
8845. Evans, P. ..... Screw propellers.
8851. Galloway & Beckwith Blowing engines.
8856. Kiddier, H. ..... Straight bar knitting machines.
8859. Lansell, G. ..... Pumps.

18th June, 1888.

8876. Welford, R. ..... Hydrocarbon engines.
8878. Tenner, A. ..... Cartridge loading machines.
8879. Fawcett & Castle..... Machinery for mixing cement.
8880. Russell, J. ..... Machines for treating fibrous plants.
8883. Vavasour, Sir W. ..... Steam traps.
8885. Carter & Cooper ..... Steam engines.
8886. Hughes & Lancaster.. Tram cars propelled by compressed air.
8890. Day, C. A. ..... Steam injectors (*Johnson*).
8892. Baddeley, C. ..... Joining the ends of rails on railroads (*Adams & Brannen*).
8906. Palmer, T. J. ..... Apparatus for embossing.
8908. Dowling, A. ..... Machines for washing & churning.
8909. Edwards, G. ..... Operating railway signals.
8911. Lake, H. H. ..... Reaping machines (*Cheney*).

19th June, 1888.

8924. Allison, H. J. ..... Picker motions for looms (*Sawyer and Douglass*).
8926. Twist, C. H. ..... Steam boilers.
8927-8. Craven, R. E. P. ..... Manufacture of metallic tubes.
8932. Bardwell, H. T. ..... Vertical mule.
8935. Clyne & Mitchell..... Stone polishing machines.
8942. Howden, J. ..... Feed water heater.
8943. Mollon & Mollon ..... Steam trap.
8963. Sayer, W. ..... Manufacturing bricks.
8964. Galloway & Beckwith Expansion valve gear.
8965. Remfuss, G., & others... Manufacture of barrel staves.
8968. Redfern, G. F... ..... Production of grooves in metal surfaces (*Société Industrielle pour la Schappe*).
8969. Edwards, E. ..... Roller bearings (*Schneider*).
8971. Fehrmann & Klug..... Machines for distributing fertilising agents.
8972. Cranston, W. McI..... Grain binding harvesters (*The Walter A. Wood Mowing and Reaping Machine Co.*).
8974. Lake, H. H. ..... Quick-firing guns and carriages (*Aktiebolaget Finsponys Styckebruk*).
8980. Lumley, P. A. ..... Manufacture of split rings.
8983. Pratt, R. J. ..... Chucks.
8984. Thompson, W. P. ..... Spinning silk (*Chapman*).
8985. Tucker, S. J. ..... Screw propellers.
8986. Wilson, J. ..... Propelling vessels.
8989. Thompson, W. P. ..... Looms (*Oldfield & Rush*).
8990. Thompson, W. P. ..... Motors (*Erwin*).
8994. Close, H. M. ..... Pumps.

20th June, 1888.

9001. Huelser, C. ..... Sewing machines (*Jansen*).
9009. Webster & Howorth.. Bending sheet metals.
9011. Woodhouse and Mitchell..... Friction clutches.
9015. Mills & May ..... Machinery for manufacturing paper.
9026. Carson, J. H. ..... Boats.
9028. Butler & Cammell ... Hydrocarbon motors.
9029. Wise, W. L. ..... Centrifugal machines for separating cream (*Jönsson*).
9031. Allen, V. I. ..... Machines for pressing hay.
9036. Carlsen, G. ..... Grinding machine for timber frame saws.
9037. Pierce, P. ..... Mowing machines.
9038. Plesner, T. ..... Grinding machines.
9039. Davidson, H. ..... Machine for reproducing articles to templet.

21st June, 1888.

9057. Bennis, A. W. ..... Boiler furnaces.
9062. Theermann, W. P. ..... Petroleum engines.
9063. Day, St. J. V. ..... Car axle lubricators (*Stever*).
9068. Brook & Taylor..... Drawing-off rollers for combing machines.
9070. Hetherington, J. M.... Detent brake for spinning and doubling spindles.
9077. Burnham, G. H. ..... Twist lace machines.
9084. Barfoot & Holmes..... Straight bar knitting frames.
9085. Cresswell, A. J..... Apparatus for stretching the wires of pianofortes.
9088. Bianchetti, B. ..... Piston for steam engines.
9090. White, L., & others ... Horizontal tubular boiler.
9094. Jones, A. S. ..... Hydrocarbon engines.

ELECTRICITY.

15th June, 1888.

8751. Wilmot, T. J. ..... Wheatstone automatic system of telegraphic transmission.
8765. Rowbotham & Fox..... Incandescent electric lamps.
8772. Rowbotham & Fox..... Electrical switches.
8784. Andersen & Tafe ..... Electrical supply.
8809. Lake, H. H. ..... Electric switches (*Berymann*).

16th June, 1888.

8836. Philpott & Alderton Safety electrical switch and fuse box.

18th June, 1888.

8871. Ryder, J. I. ..... Electrical switches.
8905. Lahousse, H., & others Electric batteries.
8912. Raison, H. ..... Electric meter.
8919. Lorrain, J. G. ..... Electric cable for high tension alternating currents (*La Société d'Exploitation des Câbles Electriques, système Berthoud-Borel et Compagnie*).
8920. Lorrain, J. G. ..... Electric cable applicable to long distance underground and submarine telephony (*La Société d'Exploitation des Câbles Electriques, système Berthoud-Borel et Compagnie*).

19th June, 1888.

8950. Burdon, C. B. ..... Electrical traction.

20th June, 1888.

9005. Wynne, F. ..... Dynamo-electric machines.
9032. Mortimer & Holloway Electric arc lamps.

21st June, 1888.

9046. Cox-Walker and Swinton ..... Magneto-electric bells.

CHEMISTRY.

15th June, 1888.

8766. Wass, A. G. ..... Utilising the residues from the manufacture of starch, glucose, starch sugar, dextrine, and alcohol.

16th June, 1888.

8840. Boake & Roberts..... Discharging excess of bleaching agent from paper pulp after bleaching.
8862. Gesner, G. W. ..... Treating metals.

18th June, 1888.

8916. Curtis & Brown..... Manufacture of compressed gunpowder.

19th June, 1888.

8922. Bang, A. ..... Dye stuffs (*Dahl & Co.*).
8925. Wilson, R. P., & others. Manufacture of metals.
8958. Wood, M. R. ..... Purification of bicarbonate of soda.
8961. Beck, W. H. ..... Depositing metals from their salts (*Levy*).

20th June, 1888.

9033. Swinborne & Swinborne ..... Treatment of hide to obtain gelatinous matters.

21st June, 1888.

9089. Wheen, F. ..... Soaps.
9091. Muller, J. A. ..... Prevention of fermentation.

MISCELLANEOUS.

15th June, 1888.

8750. Jorgensen, S. J. E..... Apparatus fixed on sextant for taking the horizon when the latter cannot be seen.
8752. Singleton, J. ..... Punching holes in straps.
8753. Macalester, J. C. ..... Castors.
8754. Corbett, J. L. ..... Clocks and watches.
8761. Wilson, J. ..... Automatic fog signalling.
8764. Lane, J. ..... Fire escape.
8779. Wilkinson and Fazackerly..... Fustian cutting knives.
8782. Fraser, W. ..... Consuming smoke.
8786. Wood, E. T. ..... Applying designs to celluloid.
8790. Darrah, C., & others... Tap unions.
8791. Brindley, C. F. ..... Pneumatic organs.
8796. Anthoni, G. C. ..... Deadening vibrations.
8798. Apps, R. T. ..... Sporting cartridges.
8799. The Electrical Combinations Company and Dingle..... Rotary brushes.
8802. Tucker, C. ..... Tricycles.
8805. Harkins, W. ..... Copying machines.
8806. Jeffery, T. B. ..... Velocipede saddles.
8807. Edwards, E. ..... Couplings for pipes (*Feyrer and Thirion*).
8808. Lake, H. H. ..... Metallic roofing plates (*Thorn*).
8812. Neu, G. S. ..... Controlling the supply of liquids to tanks.
8813. Lake, H. H. ..... Metallic roofing plates (*Thorn*).

16th June, 1888.

8818. Burrough & Verney... Carts and waggons.
8821. Neuhaus & Ascher ... Fire escapes.
8825. Sandbrook, T. ..... Valve seatings for cisterns.
8828. Taylor, R. ..... Spindle bolsters.
8834. Corden, H. ..... Ratchet braces.
8837. Smith, W. W. ..... Extinction of fires.
8846. Coutts, C., & others ... Fire escapes.
8849. Bennett, S. ..... Gas lamps.
8852. Hall, J. E. ..... Consuming smoke.
8853. Boothroyd, I. W., and others..... Velocipedes.
8855. Edwards, W. J. ..... Fire escapes.
8858. Willis, W., & others ... Measuring liquids.
8861. Wright, J. ..... Hinge.
8863. Doig, A. ..... Wheels of carriages.

18th June, 1888.

8882. Penn & Penn ..... Lamp.
8884. Vavasour, Sir W. ..... Universal wheel springs.
8888. Joyce, S. C. ..... Wheels for bicycles.
8894. Bennett, J. ..... Gas pipes or burners.
8897. Flint & Fade ..... Velocipede saddles.
8898. Grindle & Vinning ... Extinguishing fire.
8902. Boult, A. J. ..... Securing the hatches of vessels (*Bond*).
8904. Boult, A. J. ..... Printing on celluloid (*Gleason*).
8910. Lake, H. H. ..... Sewing needles (*Kempshall*).
8918. Clark, A. M. ..... Valve nut lock (*Vanwort & Devau*).

19th June, 1888.

8934. Tolson, G. ..... Preparing rags for carbonising.
8937. Knowles & Mercer..... Tappets for actuating healds in looms.
8940. Finney & Sheldon..... Decorating earthenware.
8948. Turner, W. B. ..... Finishing cartridges.
8959. Lux, F. ..... Gas burner regulators.
8966. Hopkinson & Appleton Baths or vessels containing liquids used in electro-plating or dyeing.
8967. Rhodes & Crowe ..... Hank dyeing mechanism.
8970. Lynam, J. D. ..... Range finders.
8973. Elliott, S. ..... Treatment of smoke.
8975. Stollwerck & Stollwerck ..... Stoppering bottles.
8977. Lake, H. H. ..... Stoppering of bottles (*Caswell*).
8981. Aria, C. D. ..... Treatment of fabrics and metals to render the same impervious to the action of acids, water, air, mineral oils, &c.
8982. Key, W. ..... Liquid meter.
8987. Wilson, J. ..... Preserving timber.
8995. Zalinski, E. L. ..... Dynamite shells.
8999. Clark, A. M. ..... Machine belting (*Phelps*).

20th June, 1888.

9003. Willett, S. ..... Attaching carded articles.
9006. Berkeley, H. ..... Cement.
9008. Skidmore & Jones ..... Rolling clips for springs.
9021. Macandrew, A. ..... Mounting of sails for vessels.
9023. Bannister, M. C. ..... Agitating apparatus for ice making tanks.
9027. Powell, W. ..... Propulsion of vehicles on common roads.
9040. Ellmore, W. P. ..... Locks.
9044. Dratz & Dratz ..... Dyeing materials and apparatus.

21st June, 1888.

9048. Rushton, E. ..... Brace for swifts.
9049. Phillips, F. G. ..... Aneroid barometers.
9054. Peyton, W. ..... Chimney pot.
9055. Turner, F. ..... Picks for mining.
9056. Scotson, W. ..... Prevention of corrosion of propeller blades.
9060. Thompson & Hailwood Valves of india-rubber.
9064-5. Aston, W. H. ..... Bottle stoppers.
9069. Dobbie, J. C. ..... Mariner's compass.
9073. Farini, G. A. ..... Cartridges.
9080. Robb, T. ..... Parquetry flooring.
9086. Neale, M. T. ..... Fire escapes.
9092. Lawson, J. ..... Signal lantern (*Banks & Storey*).
9093. Bollemont, E. C. de... Manufacture of vegetable fibre from wood.

COMPLETE SPECIFICATIONS ACCEPTED.

Persons interested in opposing the grant of the following patents may give notice of opposition at any time within two months after the dates given.

ABSTRACTS OF BRITISH PATENT SPECIFICATIONS.

Compiled from the Published Specifications by W. E. Heys, 70, *Market-street, Manchester.*

ENGINEERING.

Newspaper Printing Machines.—*J. H. Burton, D. Braithwaite, and M. Smith, Manchester.*—This invention relates to an improved method and means for enabling a greater amount of late news to be printed by the auxiliary cylinder than has hitherto been possible. The auxiliary cylinder is provided with one or more longitudinal dovetail recesses, and a type box fits into the recess by means of a dovetail on its under side. In order to hold the box in its position, one end of the recess is closed by an annular plate which turns round the axis of the auxiliary cylinder. This plate is provided with dovetail recesses which are coincident with those in the cylinder; and after the type box has been allowed to pass through the recess in the plate into its position in the cylinder, the plate is turned in order to throw the recesses out of register. The interior sides of the type box are radial to the centre of the cylinder, so that the type and the spacing rules must be wedge-shaped. Curved slots are formed at both ends of the recess, in order to receive the projections on the spacing rules for the purpose of preventing the type dropping out, and each type is formed with a notch which fits a corresponding ridge on the spacing rules. Six claims are made for the use of this form of type box, for the details of its construction, and special form of type and brass rules.—No. 5989. April 23rd, 1888. 8*d.*

Boiler Furnaces.—*H. H. Lake, London. (O. B. Peck, Chicago, U.S.A.)*—This furnace is designed for the purpose of utilising the waste heat of slag by employing it in the generation of steam. A plan and vertical section of the furnace and boiler are shown in the accompanying figures. The table B, which carries the slag, is provided on its under surface with a circular rack M, and the shaft L carries a gear wheel Q, which meshes with the rack M. The circular walls of the furnace A surround the table B, and are separated by a water space. The slag is discharged through the spout D upon the floor B. A blast pipe C enters the walls of

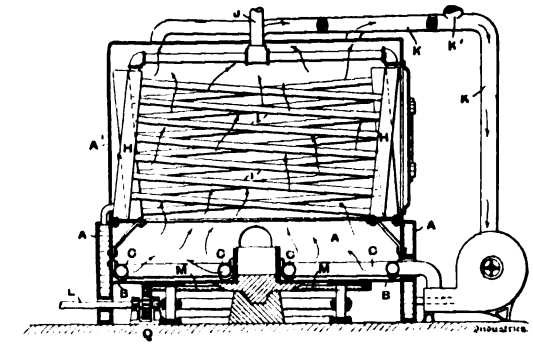

Fig. 1.

the furnace above the table and passes round its circumference, and the air issuing from it causes the slag to give up its heat more rapidly. The parts are so arranged that after the slag has been rotated with the table through one revolution all the available heat shall have been abstracted from it. The carrier E, consisting of a series of scrapers on an endless chain, serves to remove the spent slag. The chain passes through the walls of the furnace, and is rotated by two drums N N¹. As this scraper travels over the surface of the table B it removes the slag and throws it into

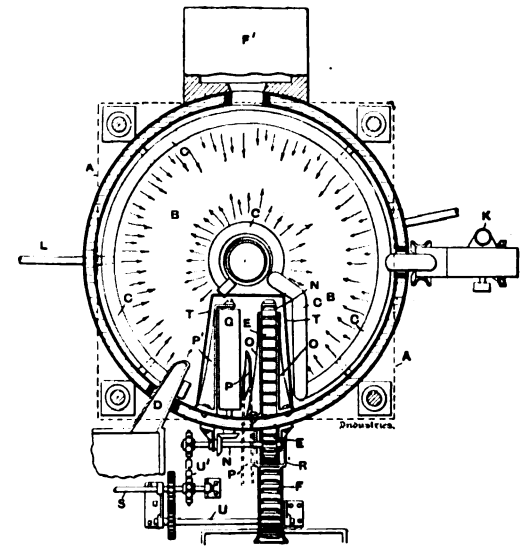

Fig. 2.

the receptacle R, from whence it is elevated by the band F and deposited upon a refuse heap. Above the walls of the furnace is the tubular boiler, in which are arranged the hollow heads H and the water tubes I. The heat from the slag passes between the tubes. At the top of the tubes there is a pipe J which carries off the live steam, and from the top of the cover a pipe K leads back to the fan which forced the air into the pipe C. The additional fire box F¹ is placed outside the furnace, so that if there should be an insufficient supply of slag an auxiliary fire may be lighted for the purpose of heating the boiler. A small spout P is placed in front of the chain E, and it allows a preparation of mud to fall upon the table before the charge of slag enters. A wheel G spreads it out and so forms a coating of fire proof material, which prevents the table from being attacked by the great heat of the slag. Six claims are made for this furnace.—No. 4708. March 27th, 1888. 8*d.*

Joining Metal Plates.—*F. C. Bellinger, Fulda, Germany.*—A joint for metal plates is here introduced, which has a greater resistive power than a soldered joint and a more advantageous exterior than a riveted joint or a fold. The joint is produced by punching elongated slits at right angles to the edge of one plate, and by bending up corresponding laps at the edge of the other plate. These laps are inserted in the slits, and then turned round, and are afterwards pressed into the plate by rolling. A narrow, flat pad, of a thickness equal to two plates, is produced, which is free from any kind of projections or depressions in its surface. On one side only the joint is raised above the level of the plates. One claim is made for this joint.—No. 8930. June 22nd, 1887. 8*d.*

Digitized by Google

CABLE TRAMWAYS.—*W. N. Colam, London.*—This invention relates to the pulleys which guide and support the cable, and its object is to reduce the size of the hatchways in the road, to lubricate the bearings more perfectly, and to simplify their general construction. Two views of a supporting pulley are given in the accompanying figures. The pulley A is preferably made in two pieces, the rim forming one piece, and the arms and the boss forming the other; and the axle D is made in one

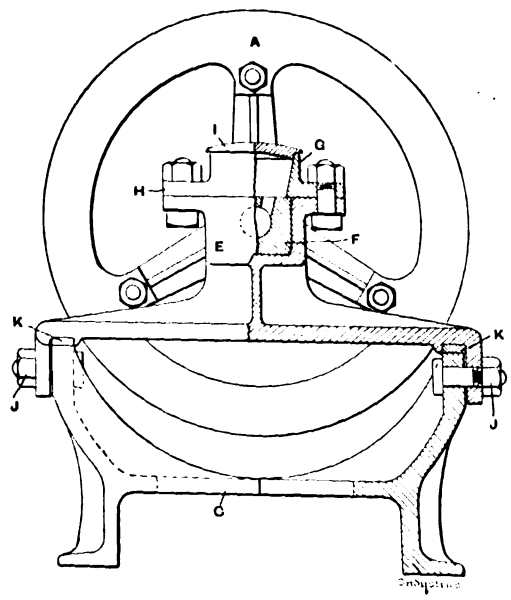

FIG. 1.

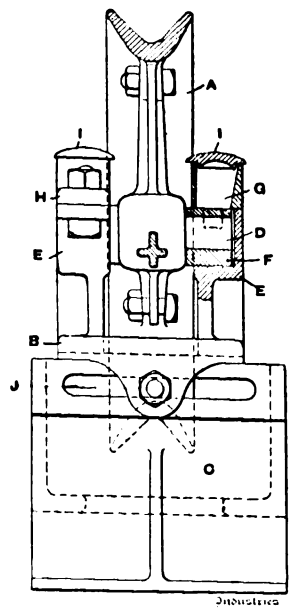
piece with the boss and arms. The pulley is mounted in a compound plummer block E B, which is self contained. The bearing blocks F are made of lignum vitæ when a cast iron axle is used. The block B is adapted to fit and slide laterally on the pedestal C, and suitable locking bolts J are provided to fix the one to the other after adjustment. Strips of wood K are interposed between the block B and the pedestal, in order to deaden the noise of the travelling cable. To insure perfect lubrication, the large grease pots G are formed in the bearing caps H, and are provided with the covers I, so that the lubricant can be introduced without removing the bearing caps. The boss of the pulley for guiding the cable round curves is made of a good length, so as to give a steady bearing, and it is preferably



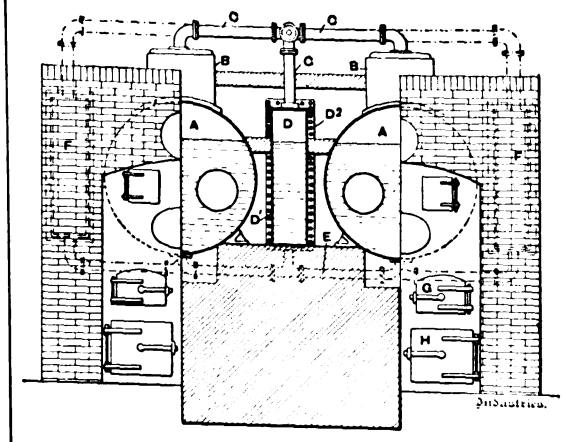


FIG. 2.

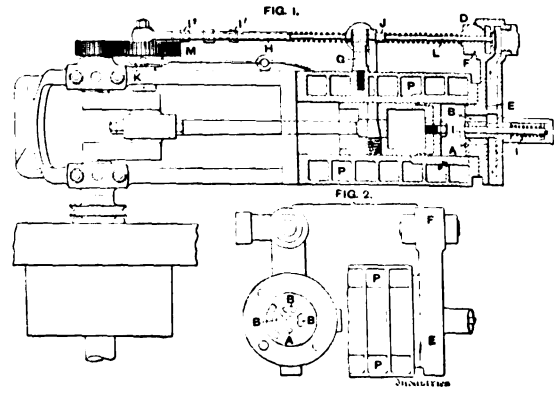
lined with white metal. The pulley runs on a steel pin fixed vertically in a shoe which is laterally adjustable. The pin has a round head at one end, and is tapered at the other to fit in a conical hole in the shoe; between the head of the pin and the top of the boss is interposed a leather washer to keep out the dirt; the top of the shoe is recessed to form an oil cup, and two steel washers are interposed between the top of the shoe and the bottom face of the boss. In order to lubricate the pulley a hole is drilled down the centre of the steel pin, and on the circumference of the pin are cut one or more oilways which are connected to the hole in the pin by suitable passages. The end of the central hole at the taper end is coned to fit the end of a tubular elbow, to which is fixed a pipe leading to the outside of the shoe, terminating in a piston lubricator. Five claims are made for the combination in the supporting pulley of the parts A B C J K, and for the construction of the guiding pulley as described.—No. 8686. June 16th, 1888. 8*d.*

STEAM ENGINES.—*J. Bureau & H. Hendlé, Paris.*—The principal feature of this invention is the method of guiding the piston of the direct acting steam engine described in the specification of Patent No. 9753 of 1886. Grooves are cut in the thickness of the cylinder for the reception of bronze rings, which also hold india-rubber rings in grooves round their circumference. The bronze rings are pressed against the slide on the cylinder cover by springs, and the lubricant is thus retained between them. Bronze wearing plates are fixed to the sides of the slide to reduce the friction, and they can easily be removed when worn. Another improvement is here introduced into the construction of the ball and socket joint of the piston rod and the stuffing box. Instead of allowing the socket to work directly against the ball, the inventors now use a lining of bronze. In order to be able to free the slide from the piston rod without having to take the piston out, the head of the piston rod is made detachable, so that the stuffing box may be simply slid off the piston rod. The reversing link is attached to a rod guided in slides on the valve box, and is connected to the valve rod by an arm, in order to gain room and at the same time to allow the eccentric rods sufficient length. Two claims are made.—No. 6485. May 3rd, 1887. 8*d.*

GIG MILLS.—*E. Michaelis, A. Smethurst, & C. Wood, Manchester.*—This invention relates to the machine described in Patent No. 11640 of 1885, granted to C. E. Moser, and consists in the application of frictional gearing for driving the raising cylinder from the countershaft, with the object of increasing the accuracy of adjustment of the range of variable speeds. Each of the raising rollers receives an independent rotary motion by pulleys from the countershaft, which in its turn is driven from an upright shaft; a friction roller, whose boss is supported by a friction clip, is mounted upon a feather key on the latter shaft, and upon a feather key on the main shaft is mounted a friction plate, which can be moved along the shaft into and out of gear with the friction clip on the upright shaft by means of a clutch lever. The friction clip which supports the friction roller is arranged to be adjusted by screws for the purpose of moving the friction roller nearer to or farther from the centre of the friction plate, and so to impart a quicker or a slower rotary motion to the countershaft and raising rollers. Two claims are made for these improvements.—No. 7844. May 31st, 1887. 8*d.*

STEAM BOILERS.—*J. W. Oldroyd, London.*—The object of this invention is to utilise the heat which is otherwise absorbed by the brick work. Instead of making the walls of the flues of brick work, the inventor replaces them by long thin steam generators, which are connected with the main steam pipe, or



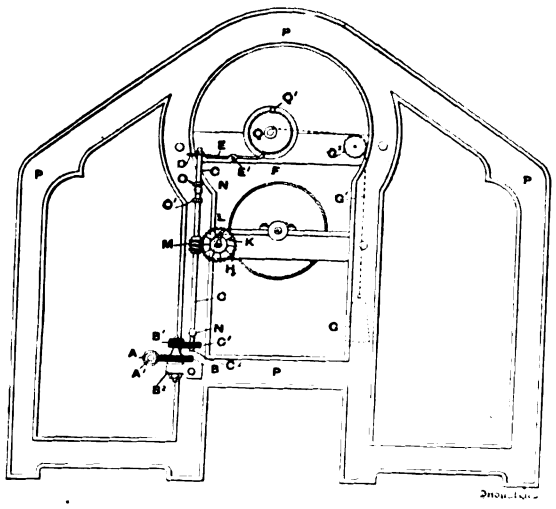
with the steam chest of the boiler. The accompanying figure illustrates an application of this method. A A are the steam boilers proper, and B their steam chests; D is the auxiliary boiler or economiser, which is constructed of boiler plates D^1, and strengthened by angle iron D^2. This economiser is connected to the boilers by the tubes E; and the steam pipes C connect the steam chests, economiser, and main steam pipe. Two claims are made for the combination of the boilers A, steam chests B, steam tubes C, and water pipes E, with the auxiliary boiler D, which is constructed as described.—No. 3216. March 2nd, 1888. 6*d.*

CONVERTERS.—*J. W. Bookwalter, Springfield, Ohio, U.S.A.*—The inventor places a cylindrical core of fire clay from one side to the other of the interior of the converter; this core is in a horizontal position, and its upper side is on a level with the tuyeres. The core occupies the position which is ordinarily assumed by a certain quantity of inert metal, because of the current generated by the air blast being a circular one. By the use of this core all the metal is equally acted on by the air blast, and there is no stationary mass of metal in the centre. Two claims are made for the use of this core.—No. 6951. May 9th, 1888. 6*d.*

DOUBLING AND TWISTING MACHINES.—*H. B. Arundel, Manchester.*—The object of the invention is to slightly raise the top roller from the bottom roller, so that the threads shall cease to be pinched between them when the thread breaks. For each top roller there is provided a thin plate or frame, through a hole in which the roller can work; this thin plate rests with two of its edges upon projections from the cap bars, and its under side is, in all positions, clear of the surface of the bottom roller. The plate is arranged to be slided to and fro, in a direction at right angles to the axes of the rollers, and when slided sufficiently forward, it comes under, and lifts the top roller clear from the bottom roller. As the top roller passes over a slight elevation on the thin plate, the latter is held from moving back too easily, except when released after the threads have been pieced together again. Instead of having a slight elevation on it, the plate may be provided with a projection to catch against one of the projections on the cap bar supporting the plate. There are bearings on each side of the plate to receive the pivots of a forked lever, whose arms are on either side of the top roller. Between the two bent ends of the arms of this lever is carried a bar of glass or earthenware; the threads after passing the delivery rollers go over the bar, and the tension of the threads in passing to the bobbin pulls down that end of the forked lever and lifts a projection at its other end, clear of a constantly oscillating bar or other mechanism. When the threads break the inner end of the forked lever comes in the way of this oscillating mechanism; the forked lever and thin plate are consequently forced forward, and the delivery of thread is stopped. When the machine is at rest the threads between the rollers and spindles may become slack, and the heavy ends of the forked levers will raise the top rollers, with the result that the threads will be broken when the machine starts again. In order to prevent this, the inventor arranges the mechanism so that the oscillations of the bar shall be stopped just before the machine comes to rest, and started a little time after the machine resumes operations; the same object will be gained by using a thin plate, which comes under and holds up the heavy ends of the forked levers just before the machine stops, and is withdrawn just after the machine has started. Four claims are made for this improved mechanism.—No. 13820. October 12th, 1887. 8*d.*

GAS ENGINES.—*J. Y. Johnson, London.* (*La Société Salomon Frères & Tenting, Paris.*)—These improvements relate to the arrangement of the admission and the exhaust valves, and to the disposition of the cooling chambers which surround the cylinder. The application of this invention to an engine working with compression and making four strokes to each explosion is illustrated in the accompanying figures; Fig. 1 shows a horizontal section of the cylinder, and Fig. 2 shows

enlarged views of the valve box. The gas and air are admitted through the valve I in the interior of the chest E, which is in one piece with the chamber F containing the exhaust valve D. The air enters the cylinder through the orifices B, and the gas enters through A; the relative area of A and B is capable of regulation. The rod H, attached to the toothed wheel M, actuates the valve rod L, and thus controls the discharge valve D. The cylinder is cast with hollow sides, and includes the vertical passages P; by this arrangement a draught of air is caused to circulate rapidly through the channels for the purpose of absorbing the waste heat from the cylinder. During the first outstroke of the piston a vacuum is produced on one side of the admission valve I, which is accordingly opened, while the spring which holds it to its seat is compressed; when the piston makes its return stroke, the valve yields to the action of the spring and returns to its seat. After reaching the end of the instroke, an electric spark explodes the mixture; during the next instroke the rod H presses against the valve rod L, and holds it open during the whole of the time occupied by this instroke. Two claims are made for the construction of the cooling passages, and for the arrangements of the ports.—No. 2804. February 24th, 1888. 8*d.*



HARVESTERS.—*J. Howard & G. Gibbs, Bedford.*—The driver's seat is so arranged in connection with the driving gear that, when the driver dismounts, the working parts of the machine are automatically thrown out of gear. In applying this improvement to a grass mowing machine, in which the seat is attached to the rear end of the pole between the two main driving wheels, the inventors connect the seat by a hinge or joint to the rear part of the pole, so that the seat is free to move a short distance in such a manner as to disengage the driving clutch the moment the driver dismounts. Another improvement relates to the method of connecting the draught appliances to the machine; the horses are made to draw from the drag bar, in addition to drawing from the pole. The whipple trees, to which the horses are attached, are connected to a long staple fixed on the under side of the pole, and are free to slide upon it within a certain limit; one end of a draught rod is attached to the hinder whipple tree, and the other end to a drag bar, in such a manner as to prevent the lifting of the driving wheels from the ground, and to carry the cutter bar lightly over the surface. It is also found that the ordinary ball and socket joint between the pitman rod and the knives is the cause of loss of time when changing the knives. By this invention the ball and socket joint is so formed that, upon raising the cutter bar to a certain angle, the pitman may be disconnected from the knife by the ball being drawn through an orifice in the socket. Three claims are made—one for each improvement.—No. 10010. July 16th, 1887. 11*d.*

BOLTING MACHINES FOR FLOUR.—*H. Coubrough, London.* (*G. Summerton, San Francisco.*)—This invention relates to an improved construction in bolting machines, by means of which the bolting cylinder, while revolving on a horizontal axis, has a constant end and side shake imparted to it, so as to give it a sifting action. For this purpose the drum, which may be of hexagonal or other shape, has its axis supported in bearings that are suspended by links from fixed brackets; the bearings are also connected to other horizontal links that are pivoted to the framing of the machine. The points of attachment of the links to the bracket and framing are by preference made adjustable in slots, so as to vary the angle of suspension of the axis. The rotary motion is imparted to the axis and bolting cylinder from a vertical driving shaft by means of a horizontal way shaft and a pitch wheel and chain; upon the vertical axis there is a cam, against which a rounded surface or anti-friction roller on the one end bearing of the axis is pressed by a spring; this spring presses against the other end bearing, so that as the driving shaft rotates, its cam,

Digitized by Google

in conjunction with the spring, imparts a to and fro end motion to the axis and cylinder, the bearings of which will swing on the suspended links, while at the same time they receive a lateral oscillating movement owing to their connection with the side links. The pressure exerted by the spring is made adjustable by means of a regulating screw. The longitudinal reciprocating motion imparted to the cylinder causes the coarser material that is retained to travel towards the discharge end, and this may be made to take place faster or slower according to the position of the links in the slots in the brackets. Two claims are made for this method of oscillating the bolting cylinder.—No. 12532. September 15th, 1887. 8*d*.

Spinning Machinery.—*H. H. Tankard & H. W. Broadbent, Bradford.*—The apparatus here introduced is intended for regulating the production of yarn or "doffings" of worsted, &c., by means of a self acting device, which stops the machine at the proper time for each doffing, and indicates the number of doffings. P represents the frame and Q the throwing off wheel. The worm wheel A is mounted on the shaft A^1 and drives the pinion B; motion is transmitted through B^1 C^1 to the rod C, on whose upper end is mounted a slotted disc D. The swing lever E is retained underneath the cam plate D, and its other end F is acted on periodically by the projection Q^1 on Q. The toothed indicating wheel H gears with the worm M, and on its surface is a series of marked divisions which correspond to the number of doffings that may be completed before the machine is stopped. K is a stop on H, which comes in contact with the pointer L, and

stops the rotation of the wheel; when this happens the worm climbs and lifts the axis C and disc D. The weight G is hung over the pulley G^2 and wheel Q. At the completion of each doffing the throwing off wheel Q is caused to rotate by the action of the weight G until the notch in the cam plate D comes over the arm E; the other end F is then disengaged from the wheel Q. At the same time this revolution is noted on the dial H by the worm M having moved it to the extent of one peripheral tooth past the pointer L. When the requisite number of doffings have been indicated the wheel H becomes fixed, and the axis and cam plate rise; the arm F is released from its hold on the wheel Q, which is caused at once to rotate by the action of the weight Q. The stoppage of the frame takes place until the attendant re-sets the regulating device. One claim is made for this apparatus for regulating and indicating the production of yarn.—No. 11472. August 23rd, 1887. 8*d*.

Gas Engines.—*C. D. Abel, London.* (*Gas Motoren Fabrik Deutz, Cologne.*)—This invention relates to that description of apparatus for igniting the charges of gas engines in which a portion of the charge is brought in contact with the interior of a tube whose exterior is heated by a gas flame. The tube, according to this invention, is arranged centrally within an annular Bunsen burner, and the outer end of this tube is closed by a removable cap. At the centre of the burner, and at about the middle of this passage, is formed a branch passage, which extends vertically upwards, and the vertical igniting tube is placed upon it. The upper end of the chamber of the burner, in which part of the horizontal passage and the lower part of the igniting tube is situated, narrows towards the tube, so as to leave only a limited annular opening, through which the mixture of gas and air entering at the lower end of the burner issues. Surrounding the part of the tube above the annular orifice is a chimney which is lined with fire clay, and perforated with a number of small openings at the level of the burner's orifice, for the purpose of permitting the air to enter. The mixture of air and gas burns in the form of an annular flame surrounding the tube within the chimney, and the supply of air being so regulated as to render the flame of a reducing character, no oxidation will take place on the tube. Four claims are made for this gas igniting device.—No. 11444. August 22nd, 1887. 8*d*.

Shaping Metals.—*T. R. Bayliss, Northfield, Worcestershire.*—The machinery constituting this invention is particularly applicable for stamping, drawing, shaping, and cutting metallic articles of a tubular form, such as cartridge cases. The machinery is double acting, so that a disc or blank can be punched out at one end of the machine, while a cupping or drawing operation is carried on at the other end. Of two sliding bolts, one carries a drawing tool, a crank shaft, and driving gear, and the other a stamping or heading tool. In place of the ordinary cast iron frame for supporting the working parts, the inventor substitutes a series of steel or wrought iron columns mounted on a strong bed plate. Two sets of the columns are used. One short set supports the lower bearings carrying the pinion shaft, the pinions, and the punch guides; and a longer set of columns supports the crank shaft, and is surmounted by a cap, to which the mechanism for working one of the sliding bolts of the punches is jointed. The sliding bolt of the machine carrying the heading punch is actuated by a knuckle motion worked from the crank shaft; the bottom of one of the links of the toggle motion is jointed to the sliding bolt, and the top of the other link is jointed to the strong cap on the top of the columns. A connecting rod is jointed at one end to the middle of the toggle motion, and at the other to the crank shaft. The crank shaft not only gives motion to the toggle joint for the purpose of working the sliding bolt of the heading punch, but also operates the sliding bolt which carries the drawing-through punch, the latter sliding bolt being connected directly to the crank shaft. The heavy work of the machine is done by the sliding bolt which is operated by the toggle joint, for by the straightening of the toggle joint great pressure is exerted on the bolt; the lighter work is effected by means of the sliding bolt worked directly from the crank. The mechanism is so arranged that as the sliding bolt at one end descends the bolt at the other end ascends, and *vice versa*. Two claims are made for this double acting machinery.—No. 12061. September 6th, 1887. 11*d*.

Pulverisers.—*H. H. Eames, Baltimore, U.S.A.*—The accompanying figures show two sections taken at right angles to each other through the apparatus. The cylinder A is made in two parts, B and C, which are held together by the hinges D and the bolts E. The material to be disintegrated is fed through the

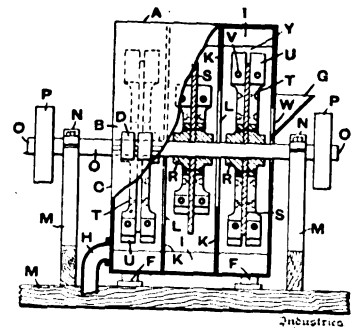


Fig. 1.

hopper G, and the resulting pulverulent material is discharged through the opening H. The shaft O carries the three flanged hubs R, on which are fixed the beater arms T and the discs S. These discs are of steel, and are provided with perforations for the purpose of allowing the finer particles to pass through from one chamber to another. In order that the material shall be

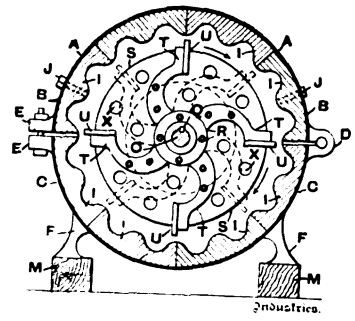

Fig. 2.

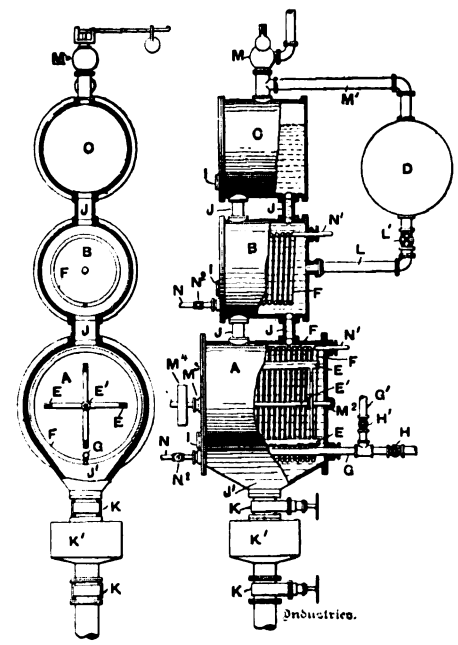
thrown against the outer casing at different angles, the cylinder is lined with the corrugated segments I. The division plates K have circular openings in their central part to allow for the passage of the material from one chamber to the next. The rotation of the hammers U and the arms T causes a current of air to be induced through the chambers, which carries the pulverised material away. Four claims are made for this apparatus.—No. 4681. March 27th, 1888. 8*d*.

ELECTRICITY.



Electrical Switches.—*J. H. Holmes, Newcastle-on-Tyne.*—The object of this invention is to insure the making and breaking of the electrical circuit being effected rapidly, although the handle be operated slowly. The movable conducting contact piece is urged from one position to another solely by the force of a spring, and is not moved directly by the handle. The force of the spring is exerted between the handle and the contact piece, and the direction of the force is altered by moving the handle to either side. The handle and the contact piece are both pivoted, and they constitute a pair of pivoted levers with a spring pressure tending to draw them in either of two directions, so that when one of them is moved by the operator through a sufficient distance, the direction of the force which the spring exerts will be changed so as to draw the other lever over to the same side. The spring is always exerting a certain amount of force on the contact piece, in order to prevent it from remaining stationary in an intermediate position. One claim is made for the form of levers and springs used for this object.—No. 5648. April 18th, 1887. 8*d*.

Secondary Batteries.—*E. E. Vaughton, Birmingham.*—The aim of most constructions of secondary batteries has been to keep the active substance of the electrodes as porous as possible. The method pursued by the present inventor, however, is the reverse, for by the continued exertion of evenly distributed pressure upon the surfaces of the electrodes, the active material is rendered as compact as possible, and is kept in perfect electrical contact with its supporter. The light plates of lead forming the electrodes may be either in the form of plain sheets or with single or double flanges, and may be perforated or not. The active material is red lead, which is applied to the supporting plate in a plastic state in a layer of a thickness equal to the depth of the flanges. When this active matter has been subjected to a uniform pressure for some time, it is found to assume the hardness of terra cotta, and it can then only be removed by chipping; and the longer the accumulator is used the tougher becomes the active material. Each active surface of the electrode is covered with canvas, and between each two pieces of canvas is placed a layer of non-conducting porous material, such as asbestos. Between such partitions are driven several pairs of wedges, so as to exert the necessary pressure. Seven claims are made for this battery.—No. 14622. October 27th, 1887. 8*d*.

Dynamos.—*L. Hanson, Halifax.*—An improvement is here introduced into the construction of the field magnets of the dynamos, which were described in Patent No. 15230 of 1886, granted to the same inventor, with the object of obtaining a more complete magnetic circuit. Molten iron is run amongst the iron wires at the pole pieces; this iron forms a solid mass with the wires, and the electric circuit is made without break or joint. One claim is made for this improvement.—No. 10240. July 22nd, 1887. 6*d*.

CHEMISTRY.

Carbonate of Soda.—*M. R. Wood, Brooklyn, U.S.A.*—The present invention relates to an improved form of apparatus for use in the manufacture of the monocarbonate and bicarbonate of soda by the ammonia process, and the object is to carry out the process with a large quantity of liquid, and at the same time to maintain substantially a specific and smaller body of solution into which the carbonic acid gas is first introduced. The lower primary vessel is shown at A, and the two secondary vessels at B C; the vessels are connected with one another by the pipes J, and the primary vessel is provided with a discharging apparatus formed of two valves K and a chamber K^1. The brine supply tank D communicates through L with the vessels B and C, and the upper vessel C is surmounted by a safety valve M. An equilibrium of pressure is thus maintained

between the vessels A B C D. An agitator E in the vessel A is formed of blades which radiate from the central shaft E^1, driven by the pulley M^4. A coil F in the vessel A communicates at one end with a supply pipe N, and at the other with a delivery pipe N^1. The flow of refrigerating material, such as cold brine, through the coil F is controlled by a valve N^2, and this refrigerant conducts away the heat of the chemical combination. A similar coil is arranged in the first secondary vessel B. The gas pipe G extends into A, and it is perforated for the purpose of distributing the carbonic acid through the liquid in A. A branch pipe G^1 communicates with the ammonia reservoir. The solution of brine in A is first impregnated with ammonia, and then a current of carbonic acid gas is sent through it; carbonate of soda thus formed is drawn off, together with the chloride of ammonia formed in the process. One claim is made for this apparatus.—No. 4284. March 20th, 1888. 8*d*.

Sulphate of Manganese.—*W. N. Hartley, Dublin, and W. E. B. Blenkinsop, London.*—In preparing the sulphate of manganese the inventors make use of the chemical reaction of the dioxide of manganese on iron pyrites. The proportions are: 91½ of pyrites "smalls" containing 47 per cent. of sulphur, and 116 of manganese ore containing from 59 per cent. to 70 per cent. of black oxide of manganese. After having been ground together under edge runners and thoroughly mixed, the materials are sifted and thrown upon the hearth of a reverberatory furnace. The charge, which at first is black, soon assumes a greenish-brown tinge, due to the formation of the sulphide and oxysulphide of manganese. After having been raised to a dull red heat, the charge is shovelled out, and thrown at once into water. Copper is commonly contained in iron pyrites, and nickel and cobalt not unfrequently occur in manganese ores; and the sulphates of these metals are formed together with that of manganese. From a solution of the salts the sulphates of the three other metals may be separated by throwing into the solution some anhydrous sulphide of manganese, and then raising the liquid to its boiling point. The sulphates of copper, nickel, and cobalt are converted into sulphides, while the manganese sulphide goes into solution as sulphate. The insoluble black sulphides of copper, nickel, and cobalt are allowed to settle, and are afterwards converted into sulphates by roasting. The sulphide of manganese used in this precipitating process may be specially prepared by heating in a crucible a mixture of sulphate of manganese and powdered coal or charcoal; or a portion of

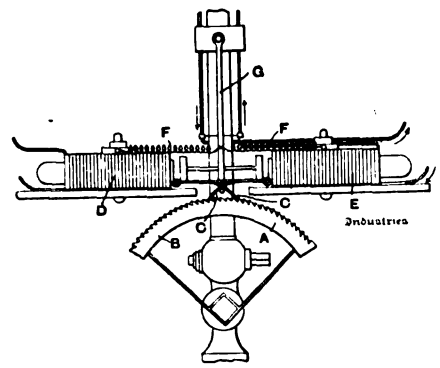
Digitized by Google

the maganese ore may be withdrawn from the furnace when in the greenish-brown condition mentioned above. Two claims are made, for the manner of making the sulphate of manganese, and for the separation of nickel, copper, and cobalt.—No. 6029. April 25th, 1887. 6*d*.

Condensing Lead Fume.—*J. B. Clark, Bristol, and The Panther Lead Company, London.*—In smelting lead ores it is customary to employ flues of considerable length between the furnace and the chimney shaft, with the object of collecting the lead which would otherwise be lost. According to the present invention the fume is led from the flue to a series of condensing chambers, each of which consists of a pipe of earthenware. The pipes are arranged in a vertical position with the lower extremities in a tank of water and their upper ends closed. Near the lower end of the pipe a branch is formed which communicates with the flue and serves as an inlet for the fume, and near the upper end of the pipe there is a branch outlet. The pipe is charged with coke or other material, which is adapted when saturated with water for condensing and arresting the fume during its upward passage through the pipe. The water is introduced in a spray or in a stream at the upper extremity of the pipe, and after percolating through the material escapes at the lower extremity. The condensed fume is carried down with the water and settles at the bottom of the tank. The uncondensed fume which may escape at the upper end of the vertical pipe is led into a chamber, which is of such a size in relation to the furnace that the velocity at which the fume traverses it shall be very moderate: the subsidence of the fume is thus facilitated. The inlet from the flue to each condensing apparatus is provided with a damper. Several vertical pipes may be grouped together with a common inlet and outlet. When using a reverberatory furnace the inventors employ an exhaust fan between the furnace and the condensing apparatus, or between the latter and the subsiding chamber. By this means the draught may be more efficiently controlled. Four claims are made for this apparatus for condensing the lead fume.—No. 9706. July 11th, 1887. 8*d*.

MISCELLANEOUS.

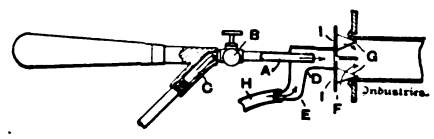
Preparing Flax.—*J. R. Garratt, Holywood, County Down, and W. Scott, Belfast.*—The object of this invention is to prevent any dust or other extraneous matter from combining with the sliver or from settling upon the drawing-off rollers. A current of air has hitherto been employed for the purpose; it has been found, however, that the dusty material is apt not to settle, but to continue circulating in the currents of air. In order to overcome this difficulty, the present inventors place a pan underneath the gills; the pan is closely fitted to the apparatus, so that no draught is induced through the flax. The dust settles down quietly without being blown about, and its subsequent disturbance is prevented by a small quantity of water in the bottom of the pan. In order to prevent any dust or other impurity from attaching itself to the drawing-off rollers, and thus impairing the efficiency of their grip, the inventors substitute metal scrapers in the place of the ordinary rubbers. The scrapers are pressed against the rollers by means of springs, and are so held that their original knife edges shall be preserved by the scraping action. If the rollers are made of wood the scrapers serve a double purpose, for not only do they remove the dust and other impurities, but they also conduct away any frictional electricity which may have been generated on their surface. Eight claims are made.—No. 17652. December 22nd, 1887. 8*d*.



Annealing Kilns for Slag Blocks.—*C. J. Dobbs, Middlesbrough.*—In the specification of Patent No. 3870 of 1883, the inventor described a kiln for use in annealing paving blocks made of furnace slag, in which the blocks were annealed by their own heat exclusively. It has been found advantageous, however, to employ a certain amount of extraneous heating to the floor of the kiln, in order to prevent any chilling of the lowest layer. According to the present invention, therefore, a pit or recess is formed below the floor of the kiln, which is made loose for the purpose; the pit is filled with a layer of suitable fuel, preferably coal, and is afterwards covered over by a floor of bricks whose joints are grouted in. Upon introducing a charge of slag blocks, the heat conducted from them passes through the floor and sets up a very slow combustion in the layer of fuel beneath. Sufficient heat is thus generated to prevent any chilling of the blocks, and the combustion will continue for so long a time that it will be only necessary to renew the layer of fuel after a number of charges of blocks have been acted upon in this manner. The floor being loose at the sides, will gradually sink down as the fuel is consumed, and thus keeps the fuel always enclosed and protected against the entrance of any more air than is necessary. One claim is made.—No. 2607. February 21st, 1888. 8*d*.

Spindles.—*P. Eadie, Paisley, R. Eadie, Manchester, and J. Eadie, Paisley.*—This invention relates to an arrangement by which the rotation of the spindles may be retarded or arrested when required. A circular cam is mounted upon a pin between each pair of spindles; the pin is fixed eccentrically upon a stud which is secured by means of a set screw to the spindle rail. A lever or handle is attached to the cam for the purpose of manipulating it when required, and the cam is surrounded by a plate whose opposite ends are concave. By turning the cam in one direction or the other, either end of this plate is caused to arrive against a collar on one of the spindles, and so to retard or stop its rotation. One claim is made for the combination of the stud, pin, cam, handle, and plate, as described.—No. 10277. July 22nd, 1887. 8*d*.

Firing Pottery.—*J. Aynsley, J. Chew, F. J. Ridgway, J. A. Chew, & J. Aynsley, Longton, Staffordshire.*—According to the method hitherto adopted, the bags for distributing the heat in potters' ovens are built close against the outer wall, the regulating flues being simply apertures left in the wall of the oven opposite the bags. It has been found that by this arrangement the ovens are not of an even temperature throughout, and that a great portion of the heat issuing from the bags is absorbed by the wall. According to the present invention, the bags are isolated, and are built at convenient distances from the oven wall, and the fire flues underneath the oven bottom are so constructed that the heat passing through them may be distributed. By this means a more even temperature is obtained, and also the bags may be surrounded by "saggars" containing the articles to be fired, and thus a greater proportion of the heat is utilised. The "saggars" may be placed uninterruptedly round the outer or largest portion of the oven, and consequently a greater number of them can be received into the oven at once. In order to regulate the heat of the ovens, the inventors build air flues from the outside to connect with the bags; the flues are fitted with suitable appliances for governing the amount of air passing through them. Two claims are made for the method of arranging the bags and flues.—No. 2206. February 14th, 1888. 8*d*.

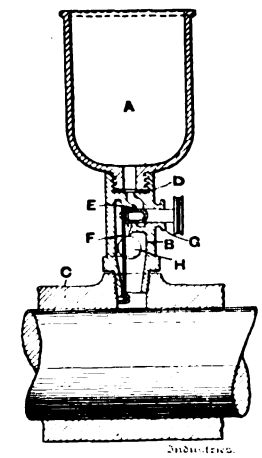


GERMAN PATENT ABSTRACTS.

Gas Tap.—*J. R. Schiller & C. Meyer, Zürich.*—This invention relates to a gas tap to which is connected an electric apparatus for lighting or extinguishing gas flames from a central station. From the gas pipe an armature G is suspended between two electromagnets D and E, and is always held in position equally distant from these electromagnets by springs F F. To the gas tap are secured two segments A and B of ratchet wheels, the teeth of which stand in opposite directions, so that when one of the

pawls C attached to G engages with the corresponding ratchet wheel it moves the tap in one direction, while the other one on engaging turns it in the opposite direction. By sending a current through one of the magnets, the armature G is attracted and one of the pawls turns the ratchet wheel, and, for instance, opens the tap. By sending the current through the other magnet, G is attracted in the opposite direction, the other pawl engages, and shuts the tap again. Wires are connected to small pieces of platinum placed just over the burner, and are heated by the current passing through them, thereby igniting the gas.—No. 43008. April 3rd, 1887.

Cleaning of Tubes.—*H. L. Currier, Lynn, Massachusetts, U.S.A.*—This method of cleaning tubes consists in directing a steam or air jet loaded with sand against the sides of the tubes. The apparatus used for this purpose consists of a tube A fitted



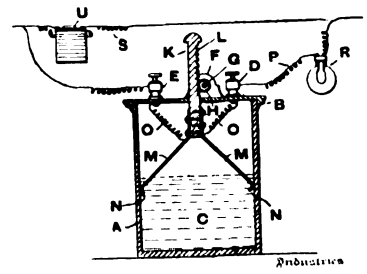
with a valve B and a steam tube C. A is connected to a short tube D provided with a sand tube H secured to a branch tube E. The tube D carries a flange I fitted with guides G, and connected to a ring F in such a manner that perforations remain between the flange I and the ring F.—No. 43033. September 10th, 1887.

UNITED STATES PATENT ABSTRACTS.

Loom Temple.—*W. H. Taylor, Hampton, Ontario.*—The T shaped frame of the temple is provided with slots for the purpose of allowing its adjustment on the breast beam of the loom. A vibrating arm is pivoted to the central arm of the frame, one end of it carrying an adjustable striking piece for contact with the lay beam, and the other being connected by means of cord to a weight which retracts the bar after it has been set by its contact with the lay. To the end of the bar is riveted a spring piece which is provided with teeth, projecting through slots in the frame, to engage the cloth, and an inclined plane in connection with the spring piece serves the purpose of lifting the teeth out of the cloth, when it meets the long arm of the frame, on the vibrating bar being struck by the lay. Two claims are made for these improvements.—No. 383501, dated 29th May, 1888.

Looms.—*H. Wyman, Worcester, Massachusetts.*—The inventor introduces an improved arrangement of the stopping mechanism for looms. The lay is provided with feelers which feel for the binders at the backward movement of the lay. The presence of a shuttle causes an arm of the feeler to act on a lever pivoted below the breast beam, and to free it from a pin on an arm of a rock shaft extending across the loom. There is a similar set of devices at each side of the loom. One of the arms of the rock shaft is extended, and is connected with a sliding rod which is normally forced by a spring towards a cam on the crank shaft. The presence of the shuttles in opposite boxes at the level of the race way entirely frees the rock shaft arms from engagement with the levers, and permits the spring to force the sliding rod into a depression in the cam as the latter is rotated; the shipper handle is thus forced out of its notch by means of a lever pivoted below the breast beam, which is hit by the arm on the rock shaft. The continued rotation of the cam re-sets the mechanism. Four claims are made.—No. 383163, dated 22nd May, 1888.

Axle Lubricator.—*G. W. Brown, West Newbury, Massachusetts.*—The flow of oil from this lubricator is regulated according to the temperature of the bearing. The cup A holds the oil, and the stem B is screwed into the bearing. The screw G is provided for the purpose of cutting off and opening the supply of oil; the oil passes through perforations in the hollow end of the screw,



and out through the valve E. A sight hole is provided at H. A double strip of metal F is screwed at one end to the bearing, and the other end carries the valve E. It follows that the degree of heating of the bearing will control the opening and closing of E, as the heat will have the effect of bending the double strip of metal F. Six claims are made for the operation of this valve by the variation of temperature.—No. 382752, dated 15th May, 1888.

Cotton Gin.—*J. R. Montague, Auburn, New York.*—According to this invention the cotton is taken from the hopper by a toothed roller, over which vibrates a cleaning card, for the purpose of opening and straightening the fibre. The cleaning card is moved concentrically with the toothed roller by means of special mechanism. A wiper roll knocks the cotton down upon a vibrating screen, which allows the dirt to fall through; from thence the cotton passes under a feed roll to the gin rolls, and is acted upon by a reciprocating rake when near to the latter rolls. The ribs upon the feed roll are arranged so as to be protruded and withdrawn by a cam. Nine claims are made.—No. 383754, dated 29th May, 1888.

Shuttles for Looms.—*J. C. Sergeson, Philadelphia.*—The spindle holding head has pivoted on it the bobbin retaining catch, which is normally forced by a spring to engage the bobbin. The head is also provided with a cavity for the reception of a knuckle, which is actuated by a spring. This knuckle serves the purpose of holding the spindle, and is formed with a lip, which engages the end of the bobbin retaining catch when the spindle is in its outer position, and so frees the bobbin from the catch. Four claims are made.—No. 383774, dated 29th May, 1888.

Rheostat.—*F. J. Crouch, Eugene City, Oregon.*—The accompanying illustration represents a vertical section of the improved form of rheostat as applied to an electric light system. The circuit includes the lamp R and the resistance coil U. The rheostat consists of a vessel A which is partly filled with a

saline solution. The vertical rod K, which is mounted in suitable slides, carries a rack L and the two conducting arms M. These arms are insulated from one another, and extend more or less into the saline solution. The rack gears with a pinion G whose revolution regulates the amount of current passing through the instrument. The wires of the circuit are attached to the arms M by means of the clamps D E and the wires O. Four claims are made for this instrument.—No. 383345, dated 22nd May, 1888.

The full specifications of the British and United States patents, and the Official Journals of the German Patent Office, from which the above abstracts have been compiled, and the Official Journal of the United States Patent Office, may be seen by subscribers and clients at the Reading Room, Manchester Office of Industries, *where also Patent Indexes from* A.D. 1617 *may be consulted. Copies of the British specifications may be obtained on application to* H. Reader Lack, Esq., *Comptroller-General, Patent Office, Southampton Buildings, London, W.C. The published price must be remitted, together with a sum sufficient to cover postage, which may be reckoned at* ½*d. for every* 10*d. or fraction of* 10*d. Remittances exceeding one shilling must be made by Post Office Order.*
